Elect

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," DEC. 25, 1891.

THE

ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOLUME VIII. (NEW SERIES.)

FROM JULY 3, 1891, TO DECEMBER 25, 1891.

THE

ELECTRICAL ENGINEER.

No. 1, Vol. VIII. LONDON, JULY 3, 1891. PRICE 3D.

NOTES.

Kidderminster.—The Bill confirming the Kidderminster electric lighting has been passed.

Carbon Trusts.—It is stated that a "trust" is being formed of the principal American electric carbon manufacturers.

Dover.—We may remind electrical engineers that the tenders for Dover electric lighting are to be sent in on the 10th inst.

Whitby.—The Bill for confirming the provisional order for Whitby has been ordered for second reading in the House of Lords.

Steam Separators.—Prof. Carpenter, of Sibley College, Cornell University, has recently carried out a series of experiments on the efficiency of steam separators.

Sales.—Our readers will notice the continued advertisement of sales of plant at the Albert-embankment and Quintin Matsy's Forge, to which we have already called attention.

French Cables.—The *Times* correspondent states that in the French Senate on Wednesday a grant of 5½ millions for cables between Marseilles and Tunis and Marseilles and Oran was agreed to.

Cardiff.—Messrs. Gilbert and Co., Hanway-street, W., have secured the contract for a complete installation at Messrs. Hopkins, Market, Cardiff, with a large number of arc and incandescent lamps.

Edinburgh Exhibition.—A second dividend, making 16s. in the pound, has been paid by the liquidator of the Edinburgh Exhibition. The materials are being sold, and a further dividend will be declared.

Telegraph in Scotland.—The Post Office extensions of the telegraph go on from time to time, reaching further and further into remote districts. One of the latest of these is to Pitlochry and Loch Tummel.

Bridge Lighting in London.—The Bridges Committee of the London County Council find there is not sufficient light on the bridges crossing the River Thames, and extra burners are to be added at the cost of £100.

Winslow (Bucks.).—The electric light was tried at Winslow on Friday evening last, when it proved a great success. Gas directors will have to take less for their gas, or, it is thought, it will not be required for the coming winter.

Swiss Electric Launch.—The Oerlikon Works, together with MM. Escher-Wyss, have built an electric boat, which has recently been launched on "Zurich's bright waters." The boat is capable of running six hours continuously, at eight miles an hour.

Spanish Cables.—Submarine cables have been laid successfully between Tarifa and Tangiers, and between Tunara, a fishing village situated eastward of the Spanish lines, and Cueta, the Spanish settlement on the Moorish side of the Striats of Gibraltar.

Selby.—Contracts are required for the lighting of the public lamps of the town, by the Selby Local Board. The prices are to be per lamp, from August 1, 1891 to May 31, 1892. Tenders to be sent in by July 3 to Mr. J. H. Bantoft, clerk, Finkle-street, Selby.

Street Lighting in France.—In reference to the paragraph under this heading last week, we are informed that the installation carried out by M. Clemançon, of Paris, is on the Bernstein system, the lamps having been supplied by the Bernstein Electric Lamp Company.

Accrington.—The Markets Committee of the Accrington Corporation have recommended the Town Council to introduce the electric light at the Town Hall, and also to consider the powers granted to the Corporation for a further extension of electric lighting within the borough.

Telephone Patents.—Our readers will notice that the National Telephone Company are calling attention to the fact that all their patents do not all expire this month, and that proceedings will be taken against persons making transmitters upon the patents which do not expire till 1892 or 1893.

Birmingham.—Mr. Charles A. Smith, of the Athenæum, 71, Temple-row, Birmingham, has been appointed agent to Messrs. Woodhouse and Rawson for Birmingham and district, and has opened showrooms at the address given, where samples of goods may be seen, as well as local orders executed from stock.

Storage Cars.—A successful electric storage car system is reported in operation in Dubuque, Iowa. After years of investigation, Mr. Rhomberg, the president of the line, has instituted this system. The cars run at 10 miles an hour, and swifter cars are to be put into operation. The Accumulator Company's batteries are used.

Cricket.—A friendly game was played on Saturday at The Elms, Acton, in a field adjoining the works of Mr. Ronald Scott, between an eleven got up by Mr. Scholey, of the *Electrical Review*, and an eleven from the works of Mr. Ronald Scott. A very enjoyable afternoon was spent, and we are informed that the return match will be played on the 25th inst.

Duke of Hamilton's Telephone.—The telephone which connects Brodick Castle and the Duke of Hamilton's shooting lodge at Dougbie with the chamberlain's house and postmaster's house at Brodick was satisfactorily completed on Saturday. The work has been executed by Messrs. Cox, Walker, and Co., electrical engineers, Edinburgh and Darlington.

Queen Anne's Mansions.—A separate company has been formed to light the Queen Anne-mansions. It has been pointed out that the London Electric and the West-

minster are the only companies who have applied or are applying for parliamentary powers in this district, and that operations of the above company will be confined to the Queen Anne's-mansions.

West Cowes.—The Local Board of West Cowes, Isle of Wight, require tenders for 160 public lamps of 20 c.p., to be fitted on the present gas lamps. The tenders are asked for oil lamps, but it is probable information on electric lighting would be received. The tenders are required to be sent in to Mr. H. J. Dament, clerk, High-street, Cowes, by July 4th.

London Lighting Company.—The Commissioners of Sewers have withdrawn their threatened opposition to the provisional order granted by the Board of Trade to the Brush Electrical Engineering Company for the electric lighting of a portion of the City of London. This order, which has already been confirmed by the House of Commons, will now pass without any further opposition through the House of Lords, no other petition having been presented against it.

Westinghouse Engine Governor.—The Westinghouse Company, after two years of experiment, are announced as having brought out a governor for high duty compound engines, whose efficiency has never been equalled. It is a combination of cranks, two springs, and heavy unbalanced eccentrics. A severe test, in which 250 h.p. was thrown off in three seconds, showed the engine to be perfectly stable on running with this governor.

Marriage.—We have to offer our sincerest congratulations to Mr. Albion T. Snell, engineer to the General Electric Traction and Power Company, on the occasion of his marriage, which took place on Monday. The employés and staff of the "Immisch" Works, at Kentish Town, presented Mr. Snell with a handsome timepiece and card-table as a mark of their respect on the occasion. Mr. and Mrs. Snell leave for a tour in Devonshire and Scotland.

German Exhibition.—This exhibition is becoming more and more successful as the season progresses. What with German exhibits, pictures, panoramas, and the magnificent dramatic representation of "Germania," to say nothing of illuminations and the splendid bands, the gardens at Earl's Court form a centre of attraction always thronged with visitors. There are some new types of oil engines and some fine electric lustres to inspect for those who require business attraction as well as pleasure.

Carshalton.—Tenders are invited by the Carshalton Local Board for the lighting of their district (consisting of the entire area of the parish of Carshalton) with gas, oil, or other illuminant at per lamp, exclusive of the costs of columns, frames, and lanterns, for 12 months from 31st July. Tenders, marked "Public Lighting," and addressed to the chairman of the Board, must be deposited at the Board offices at or before 12 noon on 8th July. Particulars from Mr. James W. Manley, clerk, High street, Carshalton.

Protection against Hail.—It appears that the country round Tarbes in France is subject to frequent and often very severe hailstorms, and, being a seat of the *petite culture*, many valuable crops and glasshouses are destroyed. The director of the observatory of the Pic du Midi, M. Vaussenat, has arranged a series of poles furnished with metallic tips, and connected by wires on the crests of the hills around, with the view of reducing the electrical tension of the clouds, and thus obviating the destructive hailstorms.

Helston (Cornwall).—A meeting of the Helston [illegible]uncil was called last week to consider the lighting [illegible] Mr. Cade moved that Mr. [illegible] Aust[illegible] asked to give an estimate for lighting the town with electricity. He thought they should try some other mea[ns] rather than cramp themselves with the Helston Ga[s] Company. Mr. Dale seconded this, for, although he could not hold out much hope that they would be illuminated with the electric light, it would be well to know the cost. The resolution was carried.

Storage Traction.—An article in the *Street Railway Gazette* on storage battery traction ends with the following sentence: "One reason for the apparent failure of the storage battery to come up to the exacting requirements of street railway service has been the attempt to do too much with too few cells, exactly as if the attempt were made to run a road with too few horses. Say, for instance, if five sets of cells were provided for two cars instead of four sets, as at present, ample time would be given to fully charge the cells, the wear and tear greatly reduced, and the service greatly improved."

Tramways Institute.—The annual meeting of the Tramways Institute, which was held yesterday under the presidency of Mr. Carruthers Wain, was well attended. Considerable discussion occurred on Mr. Kapp's paper describing the Lineff system, which is now arranged so that the insulation resistance of line is greatly increased. Messrs. Reckenzaun, Sturgeon, Dickenson, and others participated in a lively discussion. Mr. Jarman read a paper describing his system, and exhibited a model of his car. The general tone of the meeting was favourable to electrical traction, the main question being, will it pay?

Telephone Facilities in Scotland.—The Telephone Company are endeavouring to remedy the defective telephone service which has arisen between the Border towns and Edinburgh since the interposition of an exchange at Penicuik, by laying a new line between Penicuik and Edinburgh for local service only. The existing line between Edinburgh and the Border districts is to be reserved for the exclusive use of the southern towns. A new line is also to be laid *via* Peebles to connect Galashiels and the other Border centres directly with Glasgow and the West of Scotland The Kelso and Jedburgh lines will shortly be ready for use.

Zinc Elements.—Messrs. Moseley and Sons, of Manchester, are introducing a form of zinc elements for batteries, says the *Manchester Examiner*, built up by sliding tubes of thin, almost pure, zinc into one another. Each tube is amalgamated before the element is put together, and the mercury permeates the whole wall of the tube, as the latter is only $\frac{1}{32}$in. thick. The amalgamation is accordingly very perfect, and local action is entirely got rid of. The manufacturers state that when these elements are used, no time has to be spent in cleaning and scraping the zincs, which remain free from chloride of zinc and crystals till completely expended.

Telephones in Stockholm.—The Telephone Company of Stockholm have considerably reduced their charges and introduced a novel feature into their service. The charges have hitherto been £5 to £7 a year. This is now reduced to an all-round charge of 12s. only, for which instruments and wires are installed. Needless to say, for this sum everybody who has the slightest use for the telephone can have it. Besides this charge the subscribers pay 1½d. per conversation, the apparatus being supplied with a counter. Only those who use the telephone very often would have to pay rates at all high, and for these, special inclusive fees can be arranged.

The Electric Light on Snowdon.—"Sir Edward [illegible]rin," says a Welsh correspondent of a Manchester [illegible] is goin[g] [t]o do great things on Snowdon. He is [illegible] fixed at the summit of the

mountain. The light is to be so powerful as to light up every crag and precipice of the great mountain even in misty weather. Moonlight ascents of Snowdon in summer are very popular, but one would expect that they would be as nothing compared to what ascents by electric light will be if Sir Edward is able to work out his scheme. The experiment will be so novel that as soon as the news goes out that the light is on, Llanberis may count on a large influx of curious tourists."

Electric Railways.—"The longest electric railway in the world," says the *Financial News*, "is to be built between Asheville and Rutherfordton, in North Carolina. It will be 41 miles in length, and both passengers and goods will be carried. The necessary power will be obtained from a fall of water, and, when completed, the line will be the only electric railway constructed to deal with both freight and passenger cars." The line may be the longest electric railway yet built, but it is certainly an error to imagine that it will be the only electric line to deal with goods as well as passengers. The Bessbrook line, among others, constantly takes large quantities of goods traffic. It is, however, a good sign that lines of this length are being built as really electric "railways."

Babcock and Wilcox.—We notice that the prospectus is issued of Babcock and Wilcox, Limited. The share capital is stated at £240,000, of which £100,000 is to be in £10 six per cent. cumulative preference shares, and the balance in £10 ordinary shares. The vendor is to take one-third of each class of share in part payment of the purchase-money of the European patents and businesses of Babcock and Wilcox, water tube steam boiler makers. All the balance of the shares is offered to the public. It is not to be denied that the Babcock and Wilcox boilers have hitherto achieved considerable success in Europe, but £240,000 is an immense sum for the public to pay for practically "patent rights" in the boiler business, and the point is, when these patent rights run out the boiler will be open to everyone to make. We are not altogether inclined to the opinion that these boilers are the best suited to electric light purposes.

Weymersch Battery.—We have received a prospectus from the Weymersch Battery Syndicate, of Victoria-mansions, who announce that they have taken works at Colwell-road, Dulwich, for manufacture. Although the battery has been before the public some time, the directors have refrained from bringing it forward until it had repeatedly stood the test of practical work. They now announce themselves justified in recommending the battery for producing electric energy for light and motors on some scale. A battery is shown at the offices driving a Blackman's ventilating fan, and it is stated that a similar one is being used for an electric launch. A complete installation is also shown fitted up for electric light. The syndicate do not claim that the battery can compete with a large electric central station, but that it can be successfully and economically used in private houses for light and power. The mode of charging the solution is easily managed by means of simple taps.

Electric Lighting of Paris.—The *Daily News*, always the most open of our great dailies to affairs electrical, has the following note in its editorial news column: "Paris, according to Mr. Albert Shaw, is now the best lighted city in the world, and a model for all cities that are bent on introducing electric lighting on a grand scale. It is the great installation under the vast central markets of Paris that has enabled the municipality to command the situation and to carry out a scheme which has been settled, not hastily, but after a patient, scientific, and systematic study. This installation, however, has never been intended for the general work of lighting; it is for experimental purposes, and also for acting as a regulator of charges, each division of the city radiating from this centre being leased for a limited term to a responsible electric company. The old troublesome question of how to dispose of wires never arises in Paris, where, thanks mainly to the subways, there are absolutely no obstructive wires."

Visit to the Frankfort Exhibition.—At the recent meeting of the Electrical Section of the London Chamber of Commerce, one of the subjects discussed was the formation of a party to visit the Frankfort Exhibition. It was generally felt that there were greater privileges and facilities afforded in the way of guides, etc., when the visit took the form of a representative party than there would be in the case of a visit as private individuals. The authorities of the exhibition have been communicated with, and have expressed themselves favourably towards the proposed visit, which would probably extend from the 5th to the 15th September. With the view of determining whether the visit can be made in the form of a party, the secretary would be pleased to hear from electrical engineers as to whether they propose to visit this exhibition or not, and if so, whether they would wish to become one of the party, and if the date named (September 5 to 15) would be suitable.

Tramcar Tickets.—The New York *Electrical Engineer* records an admirable departure in the way of bus and tram tickets. It says the Belt Electric Line Company has abandoned the use of bell punches on its cars. Receipts are given by the conductors for cash fares. These receipts are put up in pads, 100 to the pad. Each pad has its distinctive number, and each receipt its serial number. The conductors are charged with their money receipts every night, and when they settle the next night must return the receipts in the pad, or must return cash to correspond with the missing receipts. In order that the public may be interested in receiving and taking care of these receipts they are given a money value—that is, upon the return of 100 receipts at the office of the company the bearer will be entitled to six street car tickets. In other words, the receipts are worth 1s. a hundred. This is certainly enough to justify people in saving them, and many small boys and girls will doubtless take an interest from this time on in collecting the receipts.

Simple Ammeter.—A really good, entirely satisfactory, and simple direct-reading ammeter seems yet to be invented. We have seen a simple enough one at the Acme Electric Works, the invention of Mr. Adrian D. Jones, of their testing department, late student of the City Guilds College. The "Acme" ammeter, as it is to be called, depends upon the uncoiling of a spring to compensate the varied motion of an armature in a coil. The long pointer is attached to a pivot, which is actuated by the moving armature through a long spring coiled once round the pivot before being attached. The consequence is that at the point where the greatest movement of the armature is met with, most of its motion is taken up by the spring, and comparatively little movement is given to the needle. On the other hand, in the position when little movement is given to the armature by a certain strength of current, the spring being uncoiled, the movement acts to the full extent. The scale is a long and open one, 8in. or 10in. diameter for 50 amperes, giving great space for readings. Each spring is fully tested before making up, and the instruments are carefully calibrated direct in amperes.

Testimony from Bath.—The *Bath Herald* says: "We have now had just over a twelvemonths' experience of electric lighting in our thoroughfares—the streets having

been lighted for the first time on Midsummer night last year—and though there are still a few croakers, who endeavour to pick holes and find fault with it, I question whether there are many, if any, who would like to go back to the system of lighting by gas—save and except, of course, those who from interested motives refuse to break their allegiance to the old system. Difficulties which were at first met with now appear to have been entirely overcome, and the light burns as steadily and evenly as any installation I have seen. It has already been the means of bringing the city into considerable notoriety, as evidenced by the number of deputations which have from time to time visited us from other places where the adoption of the light is under consideration, and during the electrical exhibition which is to be held at Taunton shortly, I have no doubt a stoppage at Bath will be included in the visit of all interested in the advancement of electricity as an illuminant. In course of time the Council will undoubtedly have to consider the advisability of increasing the number of lamps, by placing them closer together in certain thoroughfares which at present are insufficiently lighted."

The Speed of Electricity.—The experiments now in progress at M'Gill College, Montreal, under the auspices of the British and Canadian Governments, to ascertain the longitude of Montreal by direct observations from Greenwich, have led to the accomplishment of a remarkable telegraphic feat. The Canadian papers report it thus: "The first thing to determine was the length of time it took a telegraphic signal to cross the Atlantic. An automatic contrivance, whereby the land line could work into the cable, was provided, and a duplex circuit was arranged, so that the signal sent from Montreal would go over the land lines to Canso (Nova Scotia), thence over the cable to Waterville, Ireland, and return to Montreal again. Attached to the sending and receiving apparatus was a chronograph, which measured the time. Out of a couple of hundred signals sent, it was found that the average time taken to cross the Atlantic and back again—a distance of 8,000 miles—occupied a trifle over one second; the exact time being one second and five-hundredths. Prof. M'Leod, who is carrying on the experiments with Mr. Hosmer, the manager of the Canadian Pacific telegraphs, has left for Canso, where further experiments will be made. As soon as this work is completed, the Canadian Pacific Railway have offered their wires for determining the longitude and latitude of Vancouver, B.C."

Southampton Electric Cranes.—The Southampton Harbour Board last week had before them the draft agreement with the Southampton Electric Light and Power Company. It is proposed that the arrangement should continue for seven years, the Board guaranteeing a minimum payment of £200 a year. It was moved that this be adopted, but the period of seven years was objected, four being considered sufficient. Mr. Emanuel said that the company had stated the cost of plant would be £3,500, which at 20 per cent. would cost £700 a year, so that £200 was a small sum to ask. But the company were only entitled to charge 20 per cent. on the actual cost of conduit (£625), which would come to £125. He moved that four years be substituted. The chairman said there would be a central chamber at the bottom of the High-street, and the Board would have to take their motive power from thence to their own property. They were going to pay by meter for the motive power [illegible]ired, but if the electricity used did not cost £200 [illegible] v would still pay that sum for the term s[illegible] Emanuel was satisfied [illegible] recome[illegible] difference between seven [illegible] Th[illegible] *was carried, as was also* [illegible]

the agreement was signed they should have a complete estimate of the whole cost.

Feeder Tramways.—An interesting venture in light feeder tramways was opened this month in India, and inspected by Major Pulford, R.E., for the Government, who expressed his satisfaction with the arrangements. The line, which is a steam tramway of 2ft. 6in. gauge, is laid along the public road, and the engines are capable of travelling at 10 miles an hour. The line extends from Shahjehanpore (where it connects at a joint transshipment platform with the Oudh and Rohilkhund Railway) to Khotar, a town six miles from Milani on the L. S. and S. Railway, the total length being 31 miles. The line was carried out by Messrs. John Fowler and Co., of Leeds, through their branch at 31, Dalhousie-square, Calcutta. These small feeder lines have attracted a considerable degree of attention, as being very important additions to the large trunk railways. We mention the matter to show that the question of light railways is ripe for business in India, and although this line is worked by steam, there is every indication that, properly pushed, there might be also a considerable field for overhead conductor electric feeder lines for passengers and goods. When it is reflected that in America electricity has proved itself cheaper than horses, and actually in some cases has ousted steam, it is evident that a very large field may naturally be expected in our colonies and India.

Sad Death.—We very much regret this week to have to record the death by drowning at Hampton on Saturday of Mr. W. G. M. Mackenzie, secretary of the General Electric Traction Company. Mr. Mackenzie, who had charge of the electric boat department of the company, was living at Hampton during the summer months. On Saturday morning he went for a bathe in the backwater at Hampton before breakfast, as was often his habit, this time with a friend, Mr. Clarke, who was staying on a visit with him. Mr. Mackenzie was seized with cramp soon after plunging into the river and struggled violently. Mr. Clarke swam to his assistance, but was unable to rescue him, and was almost drowned himself, being only just saved by a boatman in a light skiff. The body was not recovered till two hours afterwards. Mr. Macpherson, managing director, was telegraphed for, and attended the inquest on Tuesday. Mr. Mackenzie was unmarried, and only 37 years of age. He was appointed secretary of the company at the time of its conversion from the Electric Traction Company and Immisch and Co. He was universally respected by the company, and by everyone who had the pleasure of knowing him, as a straightforward English gentleman. During his previous life he had passed through many and varied adventures in the South Seas and other parts, often with hairbreadth escapes. His sudden death amongst the present peaceful surroundings has caused a great shock to all his many friends.

University College Engineering Society.—At a *conversazione* held in University College, London, on Tuesday, June 30th, the above society gave an exhibition of machinery, instruments, models, and drawings in the engineering laboratory. The temporary electric lighting was undertaken by the Keys' Electric Company of London. The light was given by four arc lamps, and an electrolier with six incandescent lamps, the necessary current being supplied by one of the firm's 10-h.p. dynamos working at 110 volts, and running from a Crossley gas engine indicating 8 h.p. at 350 revolutions. The installation gave every sati[illegible]ction. The firm also lent a very complete exhibition [illegible] appliances. Messrs. Siemens Bros. and Co. [illegible]ranti also gave a very interesting [illegible]truments, as well as their electric

cables. There were several steam engines, a Worthington pump, a small alternate-current dynamo, and a model of Brotherhood's three-cylinder engine and pump in motion; whilst numerous models and photographs of Joy's valve gear, Giffard injectors, Kennedy's water-meter, brickmaking machine, torpedo, Holden's liquid fuel injector, Donkin's sprung piston rods, gas exhauster, fourway valve, and Sulzer valve gear, Hero, Newcomen, and Savory engines, a cylinder of Robey engine, with automatic valve gear, represented various branches of mechanical engineering. The laboratory testing machine, capable of exerting a pull of 100,000lb., was described, and the method of testing demonstrated; numerous tests in tension, compression, shear, and bending being displayed. The method of testing cement was fully illustrated. The engineering laboratory formed a centre of attraction throughout the evening.

Teague's Meter.—We drew attention at the time of the St. Pancras Exhibition to a new electric meter invented by Mr. Francis Teague, of Acme Electric Works. This meter promises extremely well, and has great points of advantage. Several improvements have been made in details, and it is expected, we believe, that it will be ready for the market in a few weeks. The meter is a simple embodiment of Faraday's experiment. A magnet has a large hole pierced in one of its poles, and in this the other pole projects, leaving a thin space between the solid and hollow poles, having a most intense magnet field. In this a thin metal cylinder, which carries the current, rotates by reaction of current and magnetism. The cylinder is mounted on jewelled points, and gears into a worm with dials reading direct in B. T. units. The meter has received improvements in a metal frame to prevent all warping; also the rotation of the cylinder has been damped by suitable arrangements, so that its greatest speed now is about equal to 100 revolutions only in the minute for 50 amperes. The meter, one of which we saw tested, starts very slowly, but regularly, at a current of ·2 ampere, less than that required for an 8-c.p. lamp. The motion is very sensitive, starting immediately and stopping absolutely dead when the current is turned on or off. It has only one moving part—the cylinder—besides the train of wheels, and these move so slowly that there is not much danger of wear and tear. Both wheels and pinions are made of brass to prevent any inconvenience from rust in damp places. The only possible objection is the mercury contact, and the hole through which the spindle rests is so small, and is, again, closed in by the cover, that no dust could get in. It has been carefully tested, and is correct to within 2 per cent. the whole way up from 1 to 100 lamps. Teague meters are being tested at the Pall Mall, Westminster, Kensington Court, and Chelsea stations. We expect to hear more of this meter, which is simple and should be cheap.

City Electric Lighting Bill.—The Parliamentary Committee of the London County Council report with reference to the Bill granting a provisional order for the City of London. The Bill contains a clause authorising the transfer to a single company of the undertaking of the two companies (Brush and Laing-Wharton) authorised to supply in the City of London, and also the undertaking proposed to be authorised in the district of St. Saviour, Southwark, in which the station for generating electricity to be supplied to the City of London will be situate. It is obvious, says the Parliamentary Committee, that on any such transfer some complication may arise by reason of the fact that the County Council have the appointment of inspectors generally in the county of London, and the Corporation have the appointment within the City. Moreover, the enactments in the orders within the City do not in some respects correspond with those in force outside. A difficulty also would arise in connection with the question of purchase. As the time for lodging the petition expired on the day of our meeting, the committee sanctioned the presentation of a petition, which has accordingly been presented. The attention of the Board of Trade has already been directed to this clause in their orders, but think the clause should be retained, and have retained it, so that if the petition is proceeded with it becomes rather a question of opposition to the Board of Trade by the London County Council. The clause in question provides that any transfer under the terms of it shall be on such terms and conditions as the Board of Trade impose, and the committee understand that the Board of Trade think that this would be sufficient to enable them to deal with any question which might arise. The deputy-chairman and the chairman of the Highways Committee have been requested to seek an interview on the subject with the proper official of the Board of Trade, and if satisfactory arrangements can be made, the petition may be withdrawn. In the meantime it was recommended that the course taken in presenting a petition against the Bill be approved.

City Lighting.—The Streets Committee of the Commissioners of Sewers at last week's meeting brought up a report recommending the Commission to consent to the proposed transfer of the undertakings in regard to the electric lighting of the City to a new company to be formed under the title of "The City of London Electric Lighting Company." Mr. J. L. Sayer, chairman of the committee, said that at the time the contracts were entered into it was known that they would involve an outlay of at least a million, and that the contracting companies would either have to borrow the money or form a syndicate. Mr. Morton, M.P., asked what promotion money was to be paid. They had had the experience of the Hansard Union, which was floated entirely upon the House of Commons contracts, and his opinion was that the name of the Commission had been sufficiently used already by the companies without it being further used for Stock Exchange purposes. Mr. C. T. Harris said he had ascertained that the Brush Company would receive £310,700, and the Laing, Wharton, and Down syndicate £237,000, from the proposed new company. He moved an amendment to delay the assent to the transfer of the contracts until more detailed information was forthcoming, urging that the provision for a reduction of the charges to private consumers when a 10 per cent. dividend was earned would be sacrificed if the capital was increased. Mr. Stapley seconded. Mr. Deputy Edmeston was surprised that such information should be needed when the committee were told by the managing director of the Brush Company that no money would be paid other than for materials and for work that had been done. Mr. A. A. Wood hoped that the consumers would be properly protected. The chairman said he could give the Court the assurance of the representative of the Brush Company that not a shilling was to be paid for goodwill except for works, etc., which were to be executed. Mr. Cloudesley thought that further information should be given. Mr. Morton asked whether anyone connected with the Commission was connected with any company; he saw the name of the Lord Mayor and Messrs. Pannell and Co. on a document. He was glad to see that the Lord Mayor had withdrawn his name. Mr. Pannell said his name only appeared as an auditor. In reply to Mr. Shaw, the solicitor stated that the position of the Commissioners would be in no way prejudiced by the proposed transfer. The amendment was put and lost by 18 votes to 24, and the report was agreed to.

ARC LAMP STANDARDS.

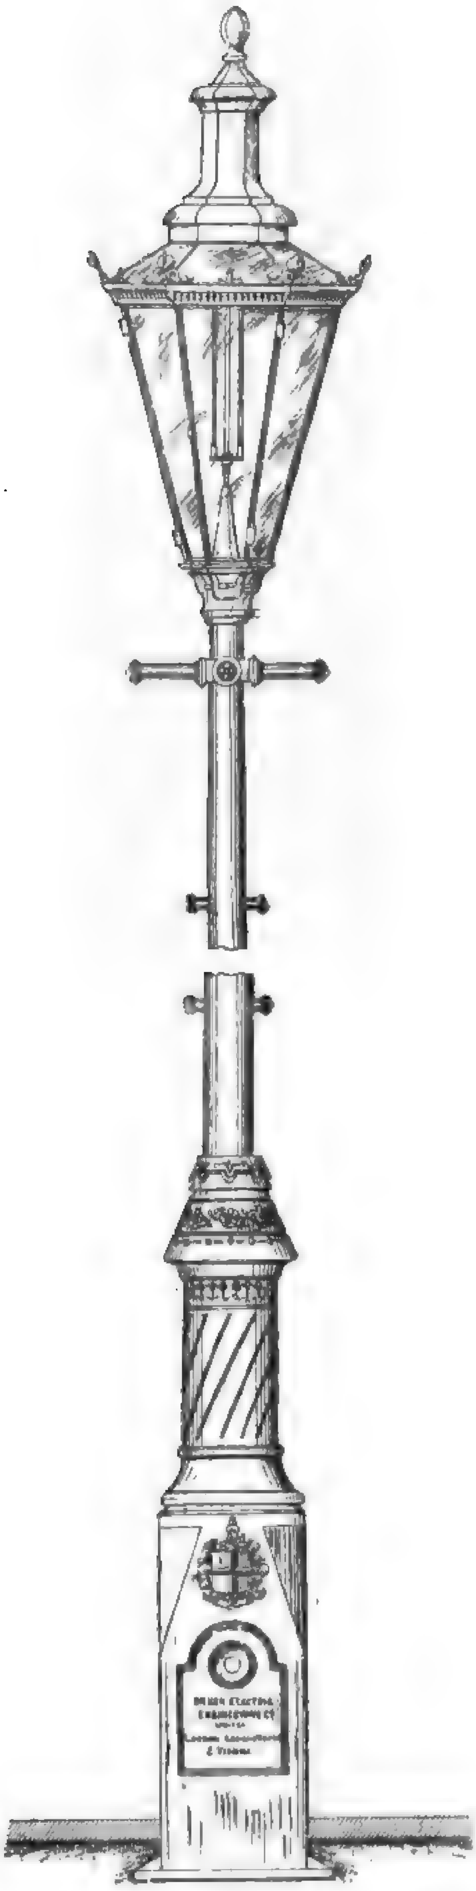

Fig. 1.

It is known to our readers that a number of arc lamps have been installed in the City in order to obtain opinions as to the suitability of the standards for such ligh Many people are of the opinion that the present o tunity is unique in character, and the time will not r again, in our day at any rate, when the design and struction of standards can be made worthy the ligh

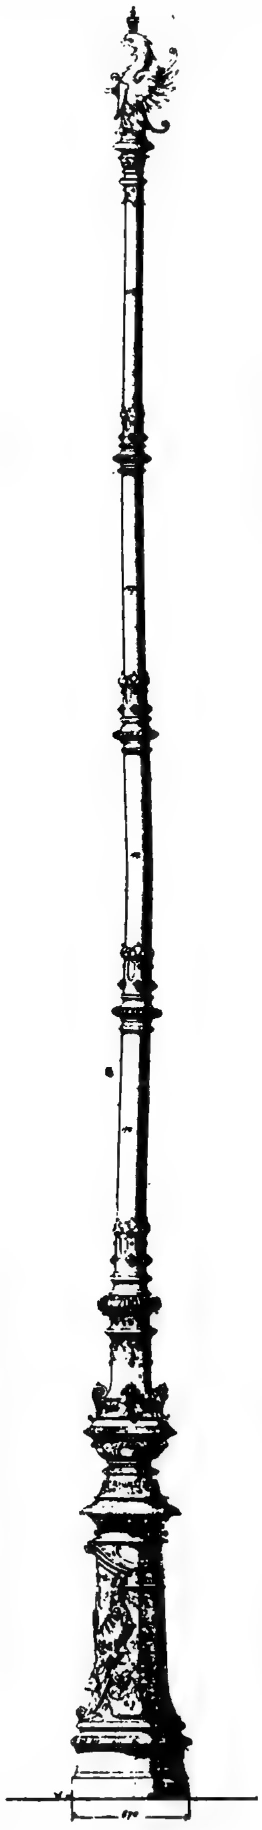

Fig. 3.

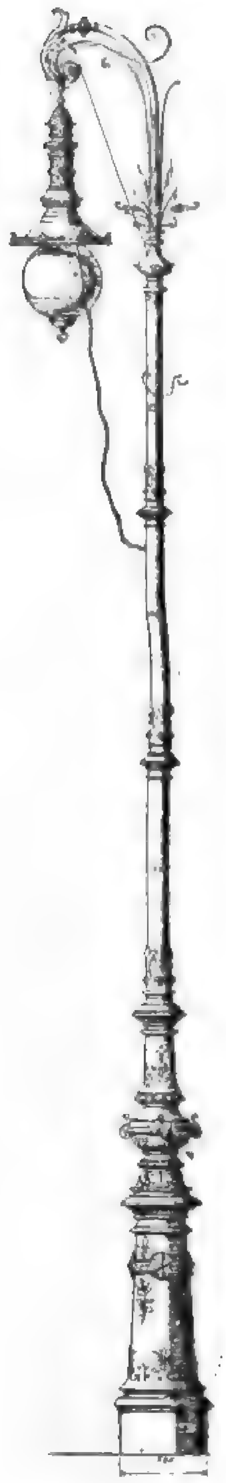

ig. 4

of the greatest city the world has ever seen. A mist too frequently made is to think that beauty of form

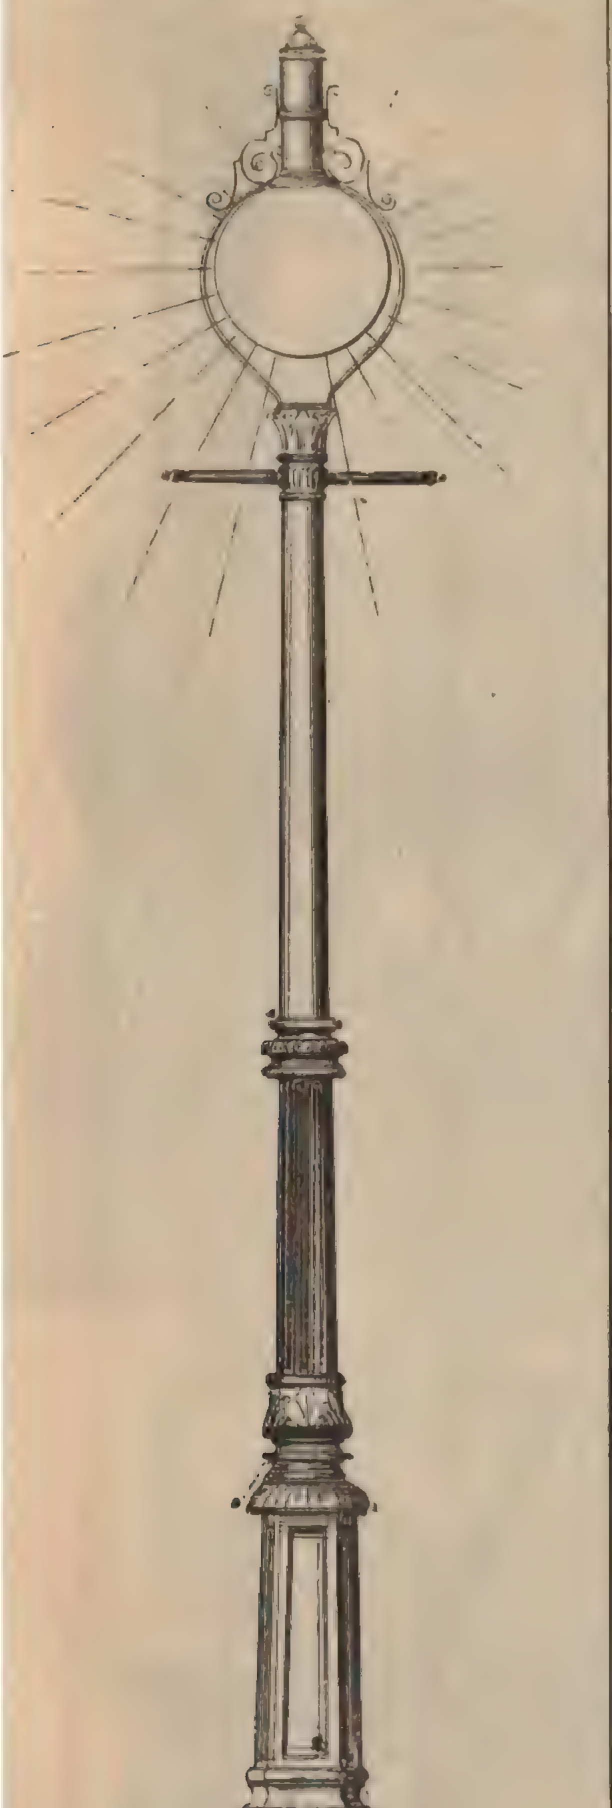

FIG. 5.

ance of design are incompatible with the bustling vity and the narrow streets of City work. The idea "anything" will do must be negatived, and a good example must be set to those towns that follow the lead of modern Babylon. We are amongst those who believe the engineers have not quite realised the possibilities of the case, and the temporary standards, as erected, seem a little deficient in artistic merit. An illustration of the standards erected in Queen Victoria-street hardly meets the case. They ought to be seen *in situ* to be able to decide as to their design. However, so far as illustrations will assist, we herewith give various designs of arc lamp standards. Fig. 1 shows the standard as erected in Queen Victoria-street by the Brush Company. To us the knobby excrescences are an eyesore, and rather put us in mind of an

FIG. 2.

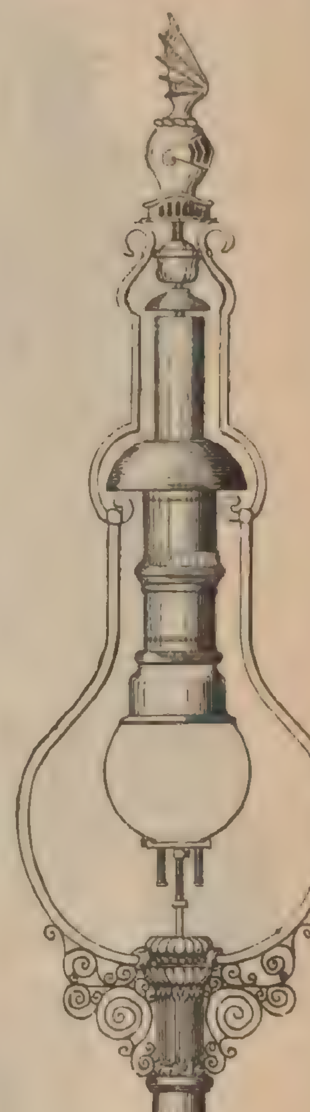

FIG. 6.

antediluvian ladder; the ornamentation and proportions of the base are also crude and inartistic. With the head of the standard we have not much fault to find, either as in Fig. 1 or as in Fig. 2, the latter of which shows the head of the standard as proposed for the portion of the City to be lighted under the Laing, Wharton, and Down Syndicate. The base and centre-piece of both standards are the same. Figs. 3 and 4 show the standards as used in Berlin; Fig. 5 is a design for a standard for the City, by Mr. W. Doubleday, of Birmingham, as is also Fig. 6.

Alhambra.—At the performance of "Oriella" at the Alhambra, all the ballet electric effects have been carried out by Mr. Chas. S. Northcote, engineer to Messrs. B. Verity and Sons.

THE ROYAL AGRICULTURAL SOCIETY'S SHOW AT DONCASTER.

We have already directed attention to the prominence of oil engines at this show. In other directions the visitor could inspect motors of the most approved type, and possessing all the improvements known to the manufacturers up to date. Of purely electrical apparatus there was little to be seen. The engineers of the society, Messrs. Easton and Anderson, used a Prentice dynamo and motor, constructed by the firm, to carry on the trials in the dairy.

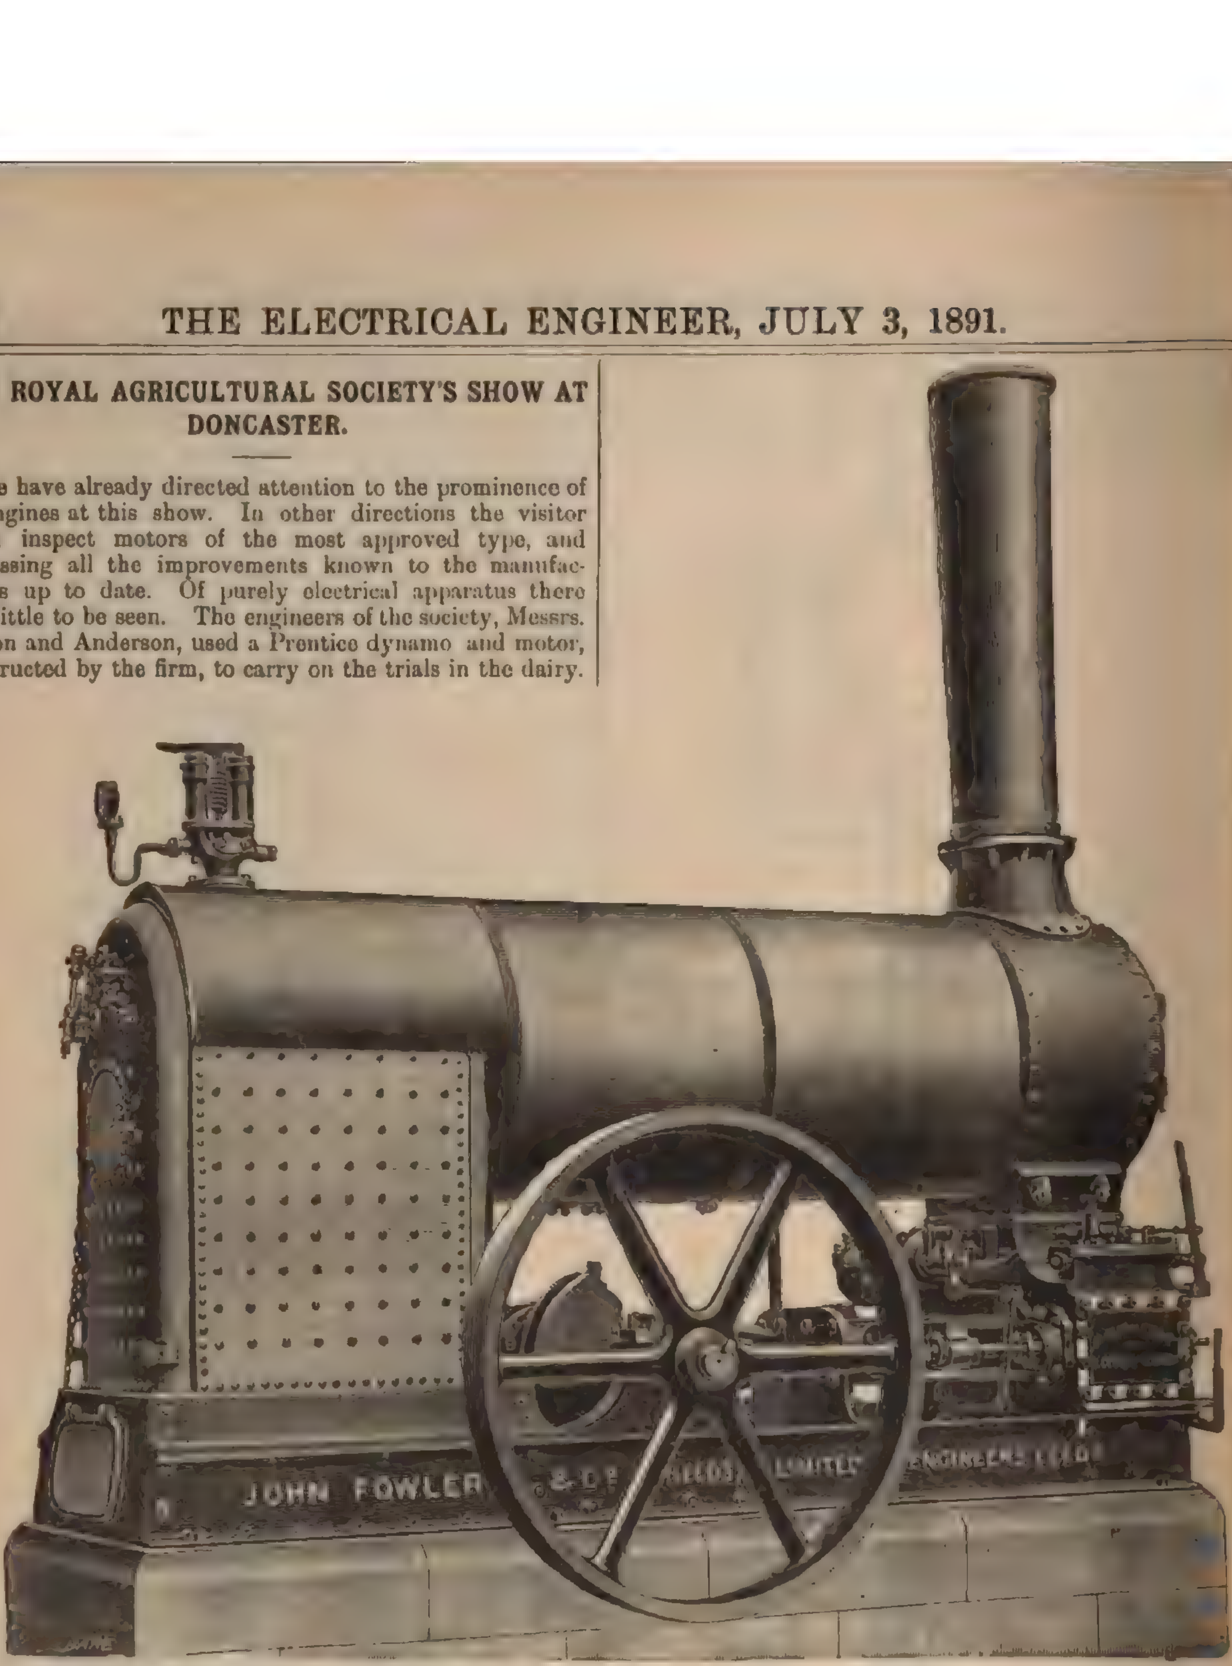

Fig. 1.

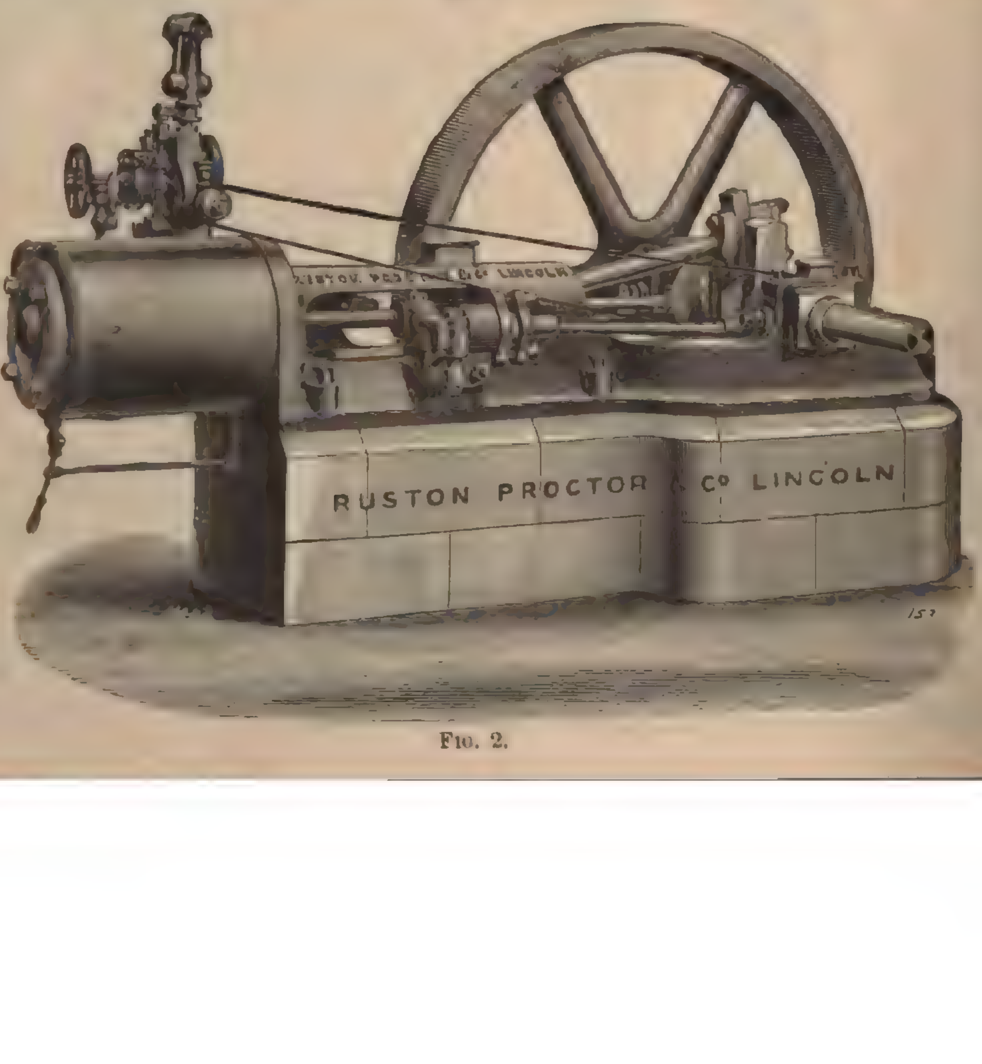

Fig. 2.

So far as we were able to judge, the apparatus was well adapted to the purpose, caused no trouble, and got rid of much objectionable shafting, enabling the trials to be among crushed bones, ore, etc. The separator was, we believe, constructed by Messrs. Goolden, and was under the charge of Mr. Atkinson. The separator is conically shaped,

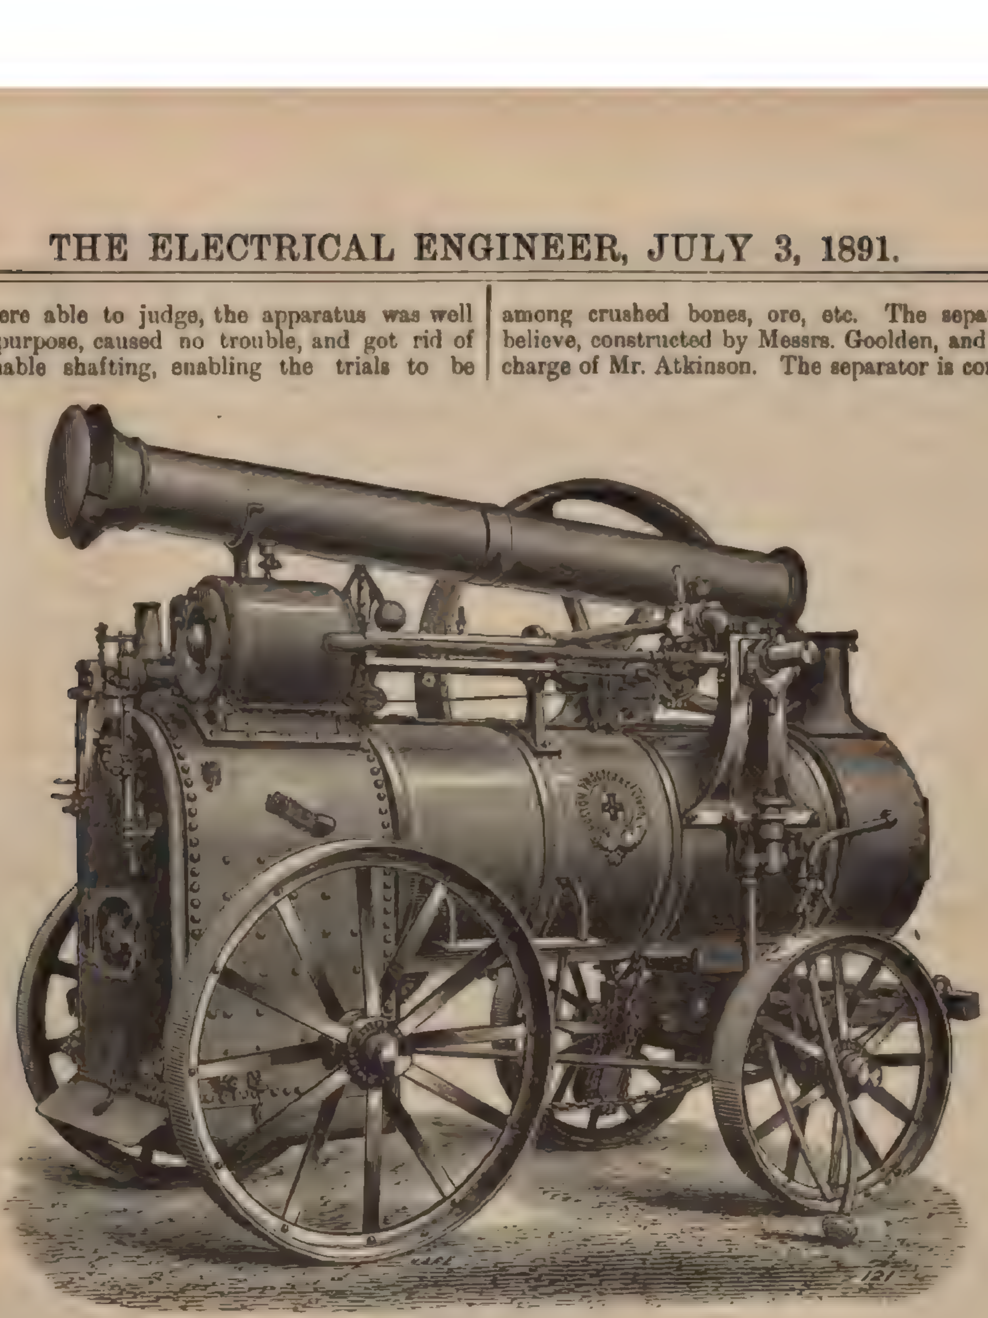

FIG. 3.

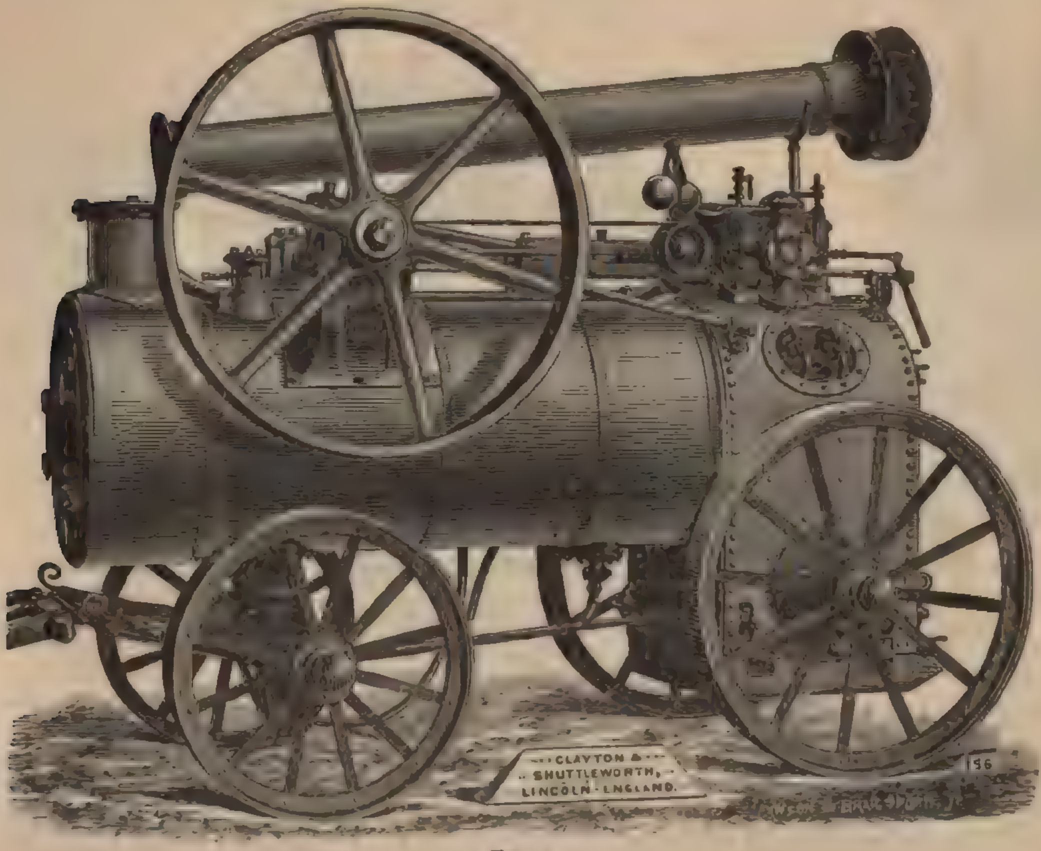

FIG. 4.

carried on at any desirable point with greater facility than has usually been the case.

The Hardy Patent Pick Company exhibited a magnetic separator, used for the purpose of extracting iron from with soft iron bars running lengthwise down the interior. These bars are wound with wire, the ends of which are carried to a commutator. The material to be treated is led into the small end of the apparatus, which revolves upon

four friction wheels, and gradually passes down and out at the larger end. During the passage the material comes again and again into contact with the magnets, and any iron becomes attached to them. The iron is carried round by the magnets, and as the action of the commutator breaks contact just as the magnets rise over a shelf, the iron drops off upon the shelf. The material traversing the cone comes about a hundred times into contact with the magnets, so that there is little probability of a piece of iron getting away.

Messrs. Christy and Carter's separator was also shown, but this apparatus needs some improvement before it can be said to be perfect.

Of engines portable, semi-portable, and horizontal, there was a fine display. Most of these engines are of the well-known types of the manufacturers, and call for little comment. Fig. 1 illustrates a semi-portable engine of Messrs. John Fowler and Co., of Leeds. Like most, if not all, of these makers' engines, Hartnell's gear is used, and the governing is such that the variation of speed is not more than 1 or 2 per cent. between full and no load. Fig. 2 shows a fixed engine by Messrs. Ruston and Proctor, and Fig. 3 a portable engine by the same firm. Since last year's show Messrs. Ruston and Proctor seem to have incorporated several improvements, the principal of which are the enlargement of the cylinder and of the firebox, so that a recent 8 h.p. is about equivalent to an old 10 h.p., with the advantage of a reduction in cost. Fig. 4 shows a portable engine by Messrs. Clayton and Shuttleworth. The workmanship of all these engines is the best possible.

(To be continued.)

THE NAVAL EXHIBITION.

The exhibit of the T. G. Electric Power and Traction Company, Limited, Maldon Works, Kentish Town, London, N.W., at the Naval Exhibition represents admirably the varied classes of work carried out by this enterprising company. It comprises both ship plant and general installation work, and shows some interesting examples of the application of electric power to machine tools and other purposes; whilst by no means the least useful part of the exhibit is a set of three-throw high lift ram pumps run by one of the company's mining motors, and a small fan coupled direct to the shaft of a motor shows a cheap, efficient, and noiseless means of ventilating crowded halls and theatres. The stall is brilliantly and tastefully lighted by a number of frosted 16-c.p. incandescent lamps in artistic fittings, many of which are especially suited for use on board ship. These lamps are run off a combined engine and dynamo, which at 320 revolutions per minute gives an output of 150 amperes and 80 volts. The plant is specially designed for use aboard ship, and conforms to the Admiralty requirements as regards heating, duration of runs, etc. On the same circuit are run the motors for driving pump, fan, tramcar gear, and machine tools. A motor and gearing similar to that used at the North Metropolitan Tramway Depôt at Canning Town and the Liverpool Tramway Company is also shown running. The motor has a cylinder armature and gives 10 brake horse-power at about 900 revolutions per minute when supplied with current at 190 volts. The armature is cased in at either end; the brushes are of carbon, in holders of a specially arranged type, patented by the company, and used most successfully by them for motors of all descriptions. The gearing consists of two transmissions, and the high-speed pinion is built up of fibre. In practice it is found that tramcars with this gear make less noise than ordinary horse cars. The same form of motor truck, slightly modified, is used by the company for light railways.

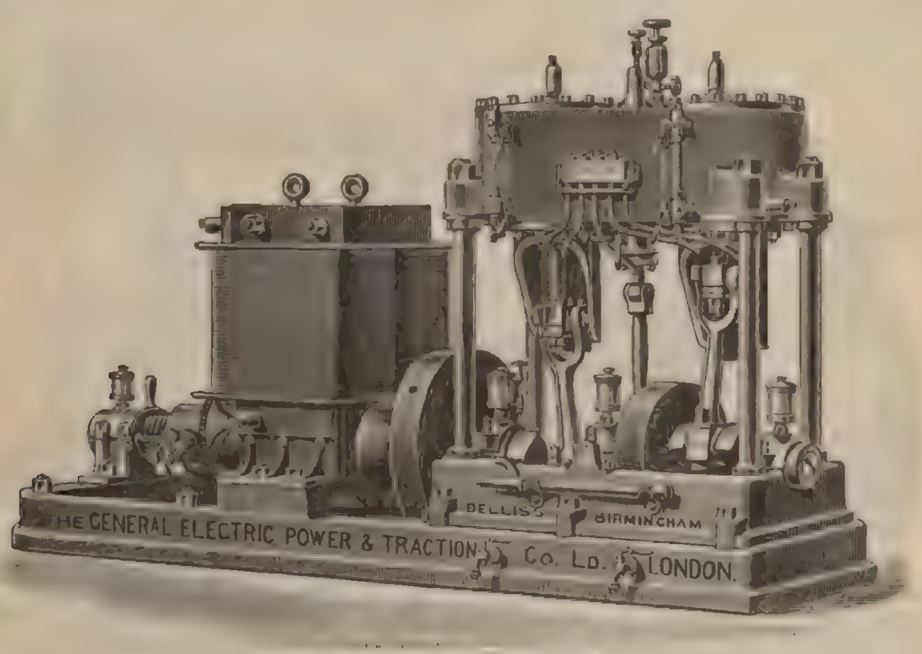
A machine worthy of special note is a portable drill, with radial arms, capable of drilling holes up to $1\frac{1}{4}$in. in iron and steel. This machine is driven by an Immisch $\frac{1}{2}$ h.p. motor, and is an admirable illustration of the portability of electric tools. It is as convenient in every respect as an ordinary power drill, and combines the further advantage of portability.

A set of three-throw pumps illustrates the company's method of applying electricity to high-lift pumps in mines. Some dozens of these plants are now at work in different parts of Great Britain, the Continent, and the colonies, and in all cases they have given the highest satisfaction, realising a high efficiency with a minimum attention, cost, and wear. The parts are so simple, and the general details so well throughout, that breakdowns are of rare occurrence, and owing to the interchangeability of parts such accidents are easily guarded against.

On the stand is also an Immisch launch motor with patent ball-bearing thrust block, such as is used by the company for general boating work. The machine is light compact, and efficient, weighs about 350lb., and develops $3\frac{1}{2}$ brake horse-power at 800 to 900 revolutions per minute. Some interesting examples of high-speed propellers are also shown, which serve to mark the advances the company have made in this branch of their work.

The boat switches fitted with three levers—one for starting and stopping through a resistance, one for full speed and half speed, and the third for running ahead or astern—are compact and workmanlike, and have now stood the test of two seasons' experience.

In the grounds just outside the Camperdown Gallery the



Combined Engine and Dynamo.

company has an electric pannace designed on the lines of the Admiralty steam pinnaces. It is 36ft. long, 7ft. beam, with a maximum draught of about 2ft. It is built in pine with oak stem, stem and stern posts, and is bright all over. The accumulators, 50 in number, are arranged in teak boxes under the seats, and are so placed as to be easily removable when necessary. The whole is so strongly built that by suitable arrangements the pinnace can be slung on davits with all electrical equipment ready for use. The cells can be charged either with the pinnace slung in the davits or moored alongside the ship. The motor is much more powerful than those usually supplied by the company for use in the launches on the Thames and at Windermere, and a speed of 11 miles per hour can be obtained for some three to four hours. Since these boats are principally used for shore purposes, speed and power have been considered of more importance than duration of run. For shore and harbour pinnaces electricity possesses many advantages over steam, and they no doubt will be largely in demand before long. These launches are ready for use at a moment's notice, and possessing none of the disadvantages of steam as regards dirt, smell, and heat, commend themselves to the consideration of all. One of these pinnaces, 40ft. long, 7ft. 9in. beam, and 2ft. draught, with a handsome teak cabin, is now being built by the T. G. Electric Power and Traction Company to the order of the Naval Department of the Russian Government; it is expected that this launch will give fully 11 miles per hour. The company have demonstrated the sea-going properties of these pinnaces; they find them to have a very steady motion even in a fairly high sea, and the centre of gravity is so well placed that the rolling is little. The motor having no reciprocating parts, runs more smoothly than a high-speed engine—this advantage will be specially felt when there is a tendency to racing of the propeller; and the whole of the electric details have been so well thought out and proved by actual experience, that there is no fear of a hitch. Since the motor and accumulator are all arranged beneath the floor and seats there is more room and greater comfort for passengers, and the carrying capacity of a given size boat is increased by about 50 per cent. The small torpedo boat running on the lake at the Naval Exhibition has been equipped by one of the company's launch motors, and the company have just received an order to build and equip a second boat of similar dimensions. The headquarters of the company's boat department are at Platt's Eyot, Hampton, where different-size launches can be seen and inspected by those interested.

There are many other interesting things to be seen at this stand, but we cannot enumerate them here; a visit should be made.

The Telautograph Again.—Prof. Elisha Gray, the noted electrician of Chicago, will give a public exhibition in July of the latest invention, the telautograph, which (says a New York telegram) is destined to revolutionise telegraphy. Prof. Gray perfected the invention in 1889, after working on it for seven years, but kept the secret until the patents were secured. The instrument not only transmits the message a long distance by wire, but reproduces at the receiving point a perfect facsimile of the message as written. Pictures and diagrams may also be transmitted. The instruments will be manufactured at Highland Park, a suburb of Chicago, and branch lines will be established throughout the country.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom............	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	[illegible]	...	17s. 4d.
Other Places..................	4s. 10d.	...	9s. 8d.	..	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VI. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

MUNICIPAL ENGINEERS.

One of the most important duties of municipal engineers in the immediate future will be to watch for and advise their respective authorities upon the introduction of electric light and power. A good deal of friction has in the past arisen between supply companies and local authorities. Each party was fighting for its own hand, and neither saw any common ground of action. It has been well said that as men grow older they grow wiser. The same holds true of those who promote new industries. Filled with enthusiasm at first, they imagine that everyone to whom they go should rush with alacrity to embrace the chance of displacing the old by the new. David's decision about the sword is too often forgotten. He would not use it because he had not tried it. The promoters of a new industry have the same feeling to contend against. Proof, in some way or other, must be given as to the advantages said to be obtained. The technical advisers of local authorities—that is, their engineers—knew little of electrical matters, and the exponents of the new departure knew little more. The latter had something which they swore by, but of its capabilities knew nothing. All were learners. For a time their progress was naturally slow. Satisfactory proofs gradually accumulated, and now greater activity prevails, while the outlook points to still greater development. The municipal and county engineers are therefore buckling down to the task of learning all they can about electrical progress. At their meeting last week several papers were read dealing with electric lighting from the municipal point of view. The most important of these is the address of Mr. W. H. Preece, F.R.S., which goes straight at the crucial point of the whole matter—its cost. Mr. Preece's conclusions are that the electric light has been vilely calumniated, and that instead of being the rich man's light, it is really the poor man's light. Once convince municipal authorities that the cost of this artificial light is not that of a luxury all will be plain sailing, for it is evident to the most sceptical mind that its other advantages are overwhelmingly in its favour against any other artificial illuminant. From many points of view gas might have been termed a diabolical invention. It is always dangerous—not openly, but insidiously so—although interested parties are ever commenting upon the smell preventing accidents; whilst with electricity there is no such danger signal. We have always held that the danger from explosion is the least of the dangers from gas. Its leakage propensities in minute quantities probably cause more headaches, more depression of spirits, conduce more to the lowering of tone of the system, and putting it in a condition to contract any prevailing epidemic, than all other causes combined. Putting, however, these questions aside, the municipal engineers have a solid substratum of data as regards cost to consider. Their visit to Ferranti's central station, to the City and South London Railway, would initiate them into the

practical part of the work. In this direction the difficulties encountered have been neither few nor simple, but for the most part have been successfully overcome, so that half a dozen or half a score of engineers would readily provide plans for the lighting of any town in the kingdom—plans which if carefully carried out would lead to perfectly trustworthy and satisfactory lighting.

VESTED INTERESTS.

The decision with reference to the Birmingham electric tramways and the telephones shows conclusively that the telephone companies will fight under the ægis of "vested interests" to obtain the monopoly of "earth return." The man in possession is a most difficult individual to deal with. Morally, his right may be objectionable, but practically he laughs at all opponents. The "earth" as a return seems naturally to come under the head of common property, just as the air we breathe; but currents do interfere with each other, and no doubt heavy currents, such as are used in tramway work, or in lighting, cannot use the same earth as telephone or telegraph currents. The case stands thus: In many places telephones have been installed, and in the majority of instances, when installed, the earth is used as the return part of the circuit. The telephone companies are private adventure concerns, and whatever profits arise go into the hands of shareholders and are not common property to the whole community like telegraphic profits. A part of the profits is paid in the shape of royalty to the Telegraph Department, and so may be looked upon as a benefit to the community, but otherwise, as we say, the adventure is one of a purely private character. Tramway work, electric lighting, electric transmission of power, are also private adventures, and from the moral point of view these adventures have just as much right to use an "earth return" as the telephone.

In no case, however, is an earth return better than a metallic return, and it is only used to save money; and this, so far as telephony is concerned, is usually saved at the expense of time and temper. The best telephone circuits are those wholly metallic. It is argued, however, that initial saving is of the utmost importance in the early stages of an industry, and that the development of telephony would be greatly retarded by insisting on the use of metallic circuits Some eminent telephone engineers dispute this, and contend that in all instances the complete metallic circuit is the best.

At Birmingham the tramway company desired to use the earth as a return, but the telephone company objected, and has won the day, in that the tramway company will have to incorporate in its Bill a clause to use a return wire. The shareholders of the tramway company, being mostly local people, are rather nettled at this decision, and a good deal of correspondence has taken place on the subject in the local Press. It will be seen, however, that the question is wider than Birmingham, and must be decided upon the wider basis. Are we to recognise the principle of "vested interests" wherever a telephone wire is installed, or is earth to be "common property," or is it to be reserved solely for the nation—*i.e.*, for the Post Office?

UNDERGROUND ELECTRIC RAILWAYS IN NEW YORK.

The question of rapid transit has been one that has been agitating the minds of engineers and municipal authorities in New York not less than in London itself. The overhead railways above the streets have made their unpleasantness abundantly felt in spite of their convenience, and further rapid transit was hardly to be looked for in this direction. Street railways with overhead conductors are equally objectionable in a large and crowded city, conduit systems have not yet shown their practicability on any scale (though they seem to promise well in this country), neither have storage cars demonstrated their absolute efficiency and economy on the scale desired. There remained the underground tube electric railway, which, without disturbing the street, has been shown by the City and South London line to give a desirable solution of the problem in point of rapidity and safety, as well as facility of obtaining the necessary space for new railway lines without encroaching on the streets. We learn that after considerable discussion, which has been going on for some months, it has just been decided to put down 20 miles of this underground tube electric railway to serve from the business part of New York to the west end suburbs. We believe it is not at all improbable, also, that a similar railway will be undertaken to give communication for the east end district.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

BATH.

SIR,—On January 30 you published among your notes the following:

"BATH.—We are glad to learn that considerable and gratifying improvements have taken place at the Bath central station. The festoons of wire and other temporary arrangements that made this station somewhat like a Yankee station have given place to the neatness and solidity that should distinguish English engineering work. The high-potential terminals also—previously a source of our complaints—are now covered in with glass and out of harm's way, and matters have smoothed over considerably since the new chief engineer took up his work there"—implying that I had left the station in these particulars in a "temporary" and "Yankee"-like condition, which I deny.

By a remarkable coincidence that number of your paper never reached me, and the above was only brought to my notice a day or two ago.

At the date of your note, and for some time afterwards, the wires were in exactly the same condition as I left them a month before, as were also the switchboards, with their high-tension terminals. Therefore "the considerable and gratifying improvements" mentioned were carried out by me, and not by the new engineer, as stated.

I much regret your inability to give the source from whence you obtained the above information, but trust you will recall these imputations against me by publishing this letter.—Yours, etc.

GEORGE S. HOOKER,
late Chief Engineer of the Bath Central Station.
184, Evering-road, Clapton, N.E., July 1, 1891.

COST OF LIGHTING BY GAS AND BY ELECTRICITY.*

BY W. H. PREECE, F.R.S.

I have the pleasure this morning of bringing before you the subject of the relative merit and cost of gas and electricity for lighting purposes, and as a practical man, speaking to practical men, I propose to consider the subject solely from a practical point of view, and to deal rather with the financial aspects of the question than the mere technics. Of course I shall have to deal a good deal with figures, and figures are proverbially dry. It has been said that you cannot extract a joke out of figures, and that you can always manipulate figures to suit your own particular view. Neither statement is quite true, because we have all of us heard the old story about the two men contesting with each other, and one man saying: "Why, sir, it is as plain as two and two make four," and the other man saying, "But two and two don't make four; two and two make 22." And, again, as to manipulating figures to suit one's own purpose, I dare say it will be said I am going to do very much that kind of thing myself. I am addressing you, if I have any prejudice at all, as a gas shareholder, and not as an enthusiastic electrician. Comparisons of cost are generally fallacious, because the comparison depends so very much upon the point of view taken. The questions we have to decide are principally such as these: what is the capital involved in any particular industry; what is the profit derived, and what has the consumer to pay? I am not going to bring before you any fanciful figures. They are published figures, and they are figures you can all get for yourselves, and you will be able to check the deductions I am going to make. I have taken the case of Manchester for the simple reason that I have more authentic records of what is done in Manchester than I have of what is done in any other town. And, from the records of the gas department in Manchester, it seems that one ton of coal in Manchester produces 9,611 cubic feet of 20-c.p. gas. I take Manchester also because it is above the average—20-c.p. gas is rather in excess of the average of the country; the average of the country is not more than 15 c.p. Since this is the quantity of gas produced by a ton of coal it follows that 1lb. of coal will produce 4·29 cubic feet of gas, and if 4·29 cubic feet of gas is burnt per hour, we get in Manchester an illumination of 17·2 candles. Now, in drawing a comparison between gas and electricity, I must use one technical term—and I think it probably will be the only technical term I shall use—and it is a technical term which is now coming into very general use, and will have to be understood by every engineer, whether electrical or municipal—that is, the term *watt*. A watt is the mechanical unit of power. The common unit of work with which we are most acquainted is the foot-pound, and the unit of power we know best is the *horse-power*—that is, the power exerted that will raise 33,000lb. one foot per minute. In other words, you may say a horse-power is the power which will raise 550lb. one foot per second. The watt is that power which in the metrical system will raise—I forget the exact value in grammes per centimetre, but it is that power which is exerted by a current of one ampere flowing through one ohm for one second. It enables us exactly to tell you how many lamps will be lighted and what light they will give. So in the use of electrical energy, if we burn in a steam boiler 7lb. of coal per hour, we shall produce 1·3 h.p. of electrical energy, or represented in watts we shal[illegible]duce 1,000 watts, and 1,000 watts is called a kilowatt. [illegible]al will give us a kilowatt-hour of electrical energy, and I will show you what light it will give. In the same way that I have shown that 1lb. of coal distilled into gas will produce 4·29 cubic feet, or 17·2 candles of light, so 1lb. of coal burnt in a boiler to produce steam will give us electrical energy that will give the following—I will show it in two forms: one *the arc lamp*, which we use in our streets, and the other *the glow lamp*, which we use in our houses—1lb. of coal burnt per hour, and used as electrical energy, if burnt in the form of glow lamp will give 48 candles, and if burnt in the form of an arc will give 288 candles. So here we start with the first theoretical fact that I bring before you, that 1lb. of coal distilled into gas in Manchester gives us a candle power of 17·2, if converted into electrical energy in the form of a glow lamp 48 candles, and in the form of an arc lamp 288 candles. That is theoretical; we will now come to hard facts. In Manchester, during the 12 months ending March 30th, 1890, the income derived from gas was £434,3[illegible], the expenditure was £360,804, showing that in Manchester a balance of £73,547 was derived from gas. That balance was devoted to meeting interest on loans, depreciation of plant, and the cost of public lighting. But from that fact I derive this: that the cost per 1,000 cubic feet of gas to the Corporation of Manchester was 2s., and therefore it costs the Corporation of Manchester 2s. to produce 4,000 candles of light. For the next point I am obliged to use an estimate for the simple reason that at present the Corporation of Manchester have not established a central electric light station. They have obtained a provisional order so as to enable them to do this, and they are now considering whether they shall carry it out themselves or transfer their powers to another body. In making an estimate of the cost of electricity in Manchester, we have to take the experience of the cost of manufacturing electricity elsewhere, and on this point there are at hand more reliable, accurate, and truthful facts than perhaps anything else connected with electricity. The Board of Trade exercise such a powerful control over the electric lighting interest, that there is no "hanky-panky" with the accounts. The accounts of expenditure must show the cost of production, and these are within the reach of everyone. My own experience of electricity is a pretty extensive one, for we have a great many of our post offices lighted with the electric light, and I have a central station at the General Post Office, which if you had not your bill full I should have been tempted to invite you to see what we are doing; we have a very large plant and we are going to produce in St Martin's-le-Grand sufficient power to light 10,000 lamps, besides which we are laying down another plant at Coldbath Fields, where we shall generate electricity for another 10,000 lamps—and from my own experience I can say we can produce a kilowatt, or a Board of Trade unit, for 4d. This means that if we can produce 4,000 candles by gas for 2s., we can produce 4,000 candles by the arc lamp for 8d., and we can produce 4,000 candles by a glow lamp for 4s. So you see, on these facts—I am not calling them estimates, for they are facts—on these facts, the theoretical estimate of light produced is twice as much by the glow lamp as by the gas lamp. However proud we, as gas engineers, may be of producing gas of 20 c.p., when you come to the houses and shops of the users and consumers you find this 20 c.p. is very considerably diminished. This is a very important question, and one which some six or seven years ago concerned us at the Post Office very much, and Mr. Vernon Harcourt, F.R.S., and myself devoted considerable time to experiments on this question. Mr. Vernon Harcourt—who is a very painstaking, careful, and accurate experimenter—found, taking the ordinary burner, supposed to be consuming 5ft. per hour and giving 15 c.p. in London, really gives only 10 c.p., due partly to dirt in the burners, but principally to the flickering of the light of the gas, caused by draughts of air in the room. So, while a light burning in a special burner in a laboratory may give 15 c.p., when you come to a room or passage that lamp will only give 10 candles. This *pro rata* value is equally true of Manchester as of elsewhere. The result is you must add 30 per cent. to the cost of the gas for your 4,000 candles. This is another point. I ought also to say this depreciation in the value of light is

* Address delivered before the London meet[illegible]tion of Municipal and C[illegible]neers.

not only true in the case of gas, but also true to a certain extent in the case of electricity. The lamps when they are still fresh and new give 16-c.p. light, but after they have been used 200 or 300 hours there is a peculiar effect of the electricity flowing through the carbon filament that causes the carbon to evaporate—it flies away in straight lines and is deposited on the glass bulb, obstructing a certain amount of light. Again, you have a certain amount of dirt and dust collected on the outside. The consequence is you have a depreciation in the amount of your electric light, though not quite so much as in the case of gas. I ought to mention, without drawing any distinction between the light-giving power—whether electricity or gas—in the light given by each, that five cubic feet of gas will give practically 10 c.p., and 33 watts in the normal power will give you also 10 c.p. There is one element of loss in gas that is very serious indeed—that is, the tremendous waste of gas that occurs through lights being left burning unnecessarily. Persons who have their houses and offices lighted with gas know that servants, as a rule, go and light all the burners, unless a careful householder goes round and cuts off those that are not wanted. The result is this: from this very element of waste there is 20 per cent. of gas used more than is necessary. This fact is brought out thus: taking the nine principal towns in this country, and taking the average numbers of hours of gas and electricity burnt in this country, the average number of hours for gas is 600, while the average number of hours for electricity is 460. The figure 460 is taken from the average of 200,000 electric lamps which are now alight in London. While in gas you have a tremendous waste from these burners being left flaring, you have no waste from electricity. Electricity is so easily lighted—a tap turns it on and off—that there is a species of instinct that teaches everyone that you only want your electricity alight in the place where you are using it, and at the moment you are using it, and the result is you get no waste. The result of it all comes to this: that the comparison between gas and the glow lamp is not 2s. as against 4s., which is theoretical, but the practical figure of 3s. 8d. against 4s. We can prove this. The average amount, taking the returns from the chief nine towns of this country, paid per gas burner per annum is 9s.; the average price of gas being 3s. per 1,000ft. The average price of the 200,000 electric lamps burning in London is 10s. So we have these two facts. That the average price paid per burner by the consumer for gas is 9s. per annum, the average price paid by the consumer to the electric light provider is 10s. This is a rather startling figure, because most people are under the impression that the cost of the electric lamp is very much greater than that of gas, and I have been myself very much surprised that the price I pay in my own house, where I generate my own electricity and have done so for the last eight years, was so very small. I find, although I have a gas engine and accumulators and have over 70 lamps, I am not paying more than when I had gas burners. I have taken all the companies in London, and have tabulated the revenue derived by each company per lamp per annum, taking the 33 watt lamp and the 10 candle burner. The Metropolitan Electric Supply Company derive a revenue of 12s. per lamp; the Chelsea Electric Supply Company, 8s. 6d. per annum; the Kensington and Knightsbridge, 9s. 2d.; the House-to-House Electric Supply Company, 11s. 6d. per annum; the St. James's and Pall Mall Electric Supply Company, 9s. 6d.; and a company, not in London, but in Brighton, obtains 8s. 6d.—the mean for 200,000 lamps being 10s. I have also verified myself this ratio between the two. In the General Post Office, where we burn a great quantity of gas, and where night operations are extended to late hours, and begin at early hours in the morning, there, from the experience of two years' working and comparison, we find that gas costs 18s. per lamp, and electricity 22s., so the ratio there is one of 9 to 11, and not of 9 to 10. Take the case of Manchester, where gas is cheaper than in other towns. The average price paid per lamp for gas in Manchester is 7s. 6d. per annum, while taking the cost of electricity to the consumer at 5d., the revenue that Manchester will derive from electric lamps will be 8s. 4d. Of course the rates of charges vary very much in London. The private companies are charging 7¼d., in other instances 8d. In Bradford they commenced by charging 5d., which they have since raised to 6d. In Newcastle they are charging 4½d. to the public, and they are allowing a large discount on that price to the large users of electricity. We in the Post Office are large users, and we have a discount of 20 per cent. off that 4½d., which makes the cost of our electric lighting in Newcastle very nearly approaching that of gas. In factories where they have isolated installations all facts show that electricity is cheaper than gas. I have figures from Bolton—from Messrs. Horrocks, Crewdson, and Co.—who are very large employers of labour in the district. They have had the electric light going for six years, and while they were using gas the cost per burner per annum came out at 5s. 6¾d. Since they generated their own electricity it comes out that their lamps cost 4s. 0¼d., so there is a considerable reduction. Those who know Manchester know that under the Exchange there is a large restaurant, which used to be unbearably hot when lighted with gas. The manager two years ago replaced gas by electricity, and he finds he is not only saving £800 a year in cost of illumination, but has probably doubled his income by allowing his guests to have their meals in comfort. So far as figures go, I have given you hard facts to show there is not much difference between the cost of electricity and that of gas. I tell all my friends that my house is lighted by gas, but I burn my gas in the garden, and allow all the vitiated gases to disappear in the air, while I extract from the gas what I want—light, and have it in the house free from all impurities. If you take 25 cubic feet of gas and burn it direct, you will only have 50 candles of light with a 10-candle burner, whereas if you burn your 25 cubic feet of gas in a gas engine, and convert it into electrical energy, it will give you 160 c.p. in the house. So, with a little care, you will be able to use the same gas and treble the amount of light in the house. I see in the programme you are going to the Royal Naval Exhibition. The Royal Naval Exhibition is lighted by electricity. There is an engine-room fitted up there with probably the latest developments of electrical machinery, for electrical machinery is constantly changing; we are daily producing improvements of some kind or other. The electrical room is well worth your visiting, and you will see there how the electrical energy is generated, and you will probably find that one dynamo and one engine is supplying the electric current to the whole of the exhibition. On Saturday you are going to have an even more interesting visit to the works of the Electric Supply Corporation, at Deptford. They are not completed, but there you will see preparations that are being made for lighting one million lamps in London. At the present moment there is only sufficient machinery to allow 200,000 lamps. You will be able to see there the space required for electrical machinery to light a million lamps. One of the great merits of electrical machinery over gas machinery is the small space which it uses. Gas requires 100ft. by 50ft. for every million cubic feet per annum; 100ft. by 50ft. is quite sufficient with electricity to light up one of our big towns. We must not neglect other points. We must not neglect the fact that when we deal with electric lighting we are removing from our midst a source of deterioration to our goods, chattels, and pictures; we are removing something which destroys our decorations, and dirts our ceilings; we are introducing into our houses something which encourages cleanliness; we add materially to our comfort, and by adding to our comfort we add very much to our cheerfulness. I know nothing which adds so much to the cheerfulness of our lives as the electric light. I feel it will even add to our lives. I feel that if I had not had the electric light in my house for the last eight years I should not have been addressing you to-day; and I hope when you meet in London 10 years hence I shall be able to come and address a larger body (for you will then be electrical engineers also), and give you experience of the progress and improvements which have been made. Another point is, that it adds so much to the security of our buildings and of our houses. It is not absolutely safe; it would be absurd to say it was. Carelessness and folly will cause fire by electric current as by gas. It requires

supervision and the usual care that engineers know so well how to exercise. But it is this question of health which I want to thrust down everybody's throat as the great merit of electric lighting, even if the price were very great indeed. We find in the Savings Bank Department of the General Post Office the cost of the electric light is actually paid for by the increased service we get out of our staff. The electric light has diminished the hours of sick absence two hours per head per annum. That put down at 10d. per hour, which is the ordinary overtime rate in the Government service, means we save £680 per annum. Our electric light costs us £700 per annum, so our electric light is really costing us only £20 a year. In the General Post Office itself we succeeded in putting in the electric light just before Christmas, and the Chief Controller told me the electric light enabled them to do their work quicker than ever before, and that the light was equal to 200 men. The purity of the air you breathe, the sanitary aspect of the electric light, is the point and aspect which commends it so much to municipal engineers and local authorities. We must not forget that gas, when let into the air, has impurities which are poisonous. Gas burnt in a bedchamber is as bad as bad water and bad smells. The chief duties of municipal engineers have been to improve sanitary matters, to remove vegetable and decaying matter from water, and by a proper system of drainage to remove all dangers from health. But the duties of a municipal engineer will not be complete until he takes in hand the electric light. This is the one point I wish to urge—that is, that the electric lamp is not the lamp of luxury. The common argument is that it is a luxury only, and that it is only the rich man who can afford to pay for it. I say the electric light is the poor man's light. If you can have the light for 8s. 4d. per annum, the benefit which a working man derives from living in a pure atmosphere, instead of in close, unhealthy, ill-ventilated rooms, makes it worth the serious consideration of our home authorities. The price of gas is going up; the price of electricity is coming down. The price of gas is going up from labour disputes and strikes; the price of electricity is coming down because we know so very much more about it. I have not said much yet about the relative cost of production of gas and the electric light. We can produce 1,000ft. of gas for 1s. 10d.; the extra 2d. is for management and collection, though I have no doubt under certain conditions gas engineers can produce it for 1s. 7d., or 1s. 4d., or even 1s. What can we produce electricity for? It so happens I have just been making exhaustive enquiries as to the cost of electricity in the production of phosphorus and copper. These are two industries where the use of the current is uniform and continuous, and the engines, dynamos, and everything working at their maximum efficiency. In electric lighting the use of the light is irregular. People will not go to bed at the same hour, or rise at the same hour, or all use the light together, so that the "load line" is variable. Where the load line is constant—and in works where copper and phosphorus is produced it is constant—you can produce your electricity for ⅓d. per unit. There is no mistake about that figure—the cost of production of a unit of electricity on a large scale, with a constant load, is one-third of a penny. What does that mean? If we take the theoretical difference between gas and electricity, it is equal to gas produced at 3d. per 1,000ft When we have the prospect of producing electricity at one-third of a penny per unit, equivalent to gas at 3d. per thousand, it shows that a vast field of development is before us. There is one reason why gas is still ahead of electricity. It is that there is such a market in this country for residuals, the price obtained for coke and ammoniacal liquor and the other ingredients of gas works, practically reduces the price of coal to the gas manufacturer in London to 4s. 6d. per ton. We have to pay in London for Welsh coal 23s. per ton. That is why we have to pay more for electric light than for gas. When we come to Gibraltar and Malta, where I recently went to see whether it was possible to introduce the electric light, there is no market for residuals, and it required no difficulty on my part to show that it was possible to produce electricity c[illegible] an gas. I have endeavoured to the best of my [illegible] ng this *matter before you* as practical men, [illegible], if you agree with my conclusions, to point out to your different boards that the duty of a corporation is to look into this matter not only from a financial, but from a political as well as a sanitary point of view, and, above all, from a philanthropic point of view, and to endeavour to persuade, as I have endeavoured to persuade you, that the electric light is the light of the future, and not the light of luxury, but the poor man's lamp.

ELECTRIC LIGHTING BY MUNICIPAL AUTHORITIES.*

BY PROF. HENRY ROBINSON, M.I.C.E., M.I.E.E.

As this is the first occasion on which I have met the association since the council paid me the compliment of electing me an honorary member, I desire to express my high appreciation of the honour conferred on me thereby. I gladly accede to the wish expressed to me that I should bring before this meeting the subject of electric lighting, especially from a municipal point of view. The supply of electricity to the community may now be regarded as one of the requirements of the day, and it is of first importance to municipal authorities to consider the expediency of preserving the supply in their own hands Many have lost the opportunity, and have allowed companies to obtain powers over their areas. Many are now deliberating upon the point or are in conflict with companies, and, as I think the question is ripe for decision, and I hold that it is not so advantageous for these undertakings to be carried out by private enterprise, and by outside capital, as it is by capital raised on the rates, whether from a financial or public point.

When Mr. Chamberlain, as President of the Board of Trade, in 1882 was engaged in the lengthened enquiry on the subject of electric lighting (which resulted in the Act of that year), an organisation, composed chiefly of delegates of the principal municipal corporations, urged upon the Board of Trade the necessity for entrusting the supply of electricity to local authorities, in preference to companies, in order to avoid the creation of another monopoly like gas and water, and to ensure the profits of the undertaking being secured to the ratepayers instead of to outside companies. A prominent part was taken in the action at that time by Mr. T. Eccleston Gibb (the vestry clerk of St. Pancras), whose judgment and experience in affairs relating to municipal government is probably second to none in the kingdom. He held the strong opinion that the authority should keep the powers in their own hands and Dr. Hopkinson, F.R.S., and myself were consulted at that time with a view to this policy being pursued in the St. Pancras district. The result was that a provisional order was obtained in 1883, by which all the companies were and have been ever since excluded from this district, and in this respect St. Pancras has been an exception to the rest of the metropolis in having acquired these powers. The onerous conditions imposed on companies by the Act of 1882, together with the failure of the most prominent companies to realise the anticipations that had been held out by them, led to a period of suspense which was beneficial, inasmuch as during that interval many technical and practical difficulties were overcome as regards the production and supply of electrical energy. In the year 1888 an amending Act was passed, under which many of the onerous conditions were removed, and by which the monopoly acquired by any company was extended to 42 years. By this time numerous able and enterprising inventors had been devoting themselves to perfecting the machinery for producing the supply of electricity, and of the methods of distributing it. During these years the Patent Office presents a record of inventions probably unique in the history of that department, and whatever opinion may be held as to who should undertake the work, the thanks of the community are undoubtedly due to those who served as pioneers. The time had then arrived when (as I stated to the St. Pancras Vestry in March, 1889) a public body need no longer hesitate to engage in the business, and from the points of view of finance and

* [illegible]ead before the London meeting of the Association of Muni[illegible]ounty Engineers.

general convenience it was most desirable for the business to be undertaken by the authority. As regards finance, the authority can provide the necessary capital at a far lower rate than a company can, and as regards convenience, the public lighting of the streets, the disturbance of roads, and the sanitary advantages of substituting electric light for gas in dwellings, point to their being matters that clearly devolve on the authority to deal with. The wide field that is open for the employment of electrical energy for motive power, tractive, and public lighting purposes, is also a further reason for the supply being in the hands of the authority.

I think it will be useful to put on record in your *Proceedings* calculations that I have made of the relative cost of gas and electricity which have appeared in various reports of mine, when advised on the subject of electric lighting.

TABLE SHOWING COST OF GAS LIGHTING.

Description of burner.	Candle-power.	Consumption of gas per hour per lamp.	Candle-power per cubic foot used per hour.	Cost per hour with gas at 2s. 9d. per 1,000 cub. ft.	
				Per lamp.	Per c.p.
		Cubic ft.		Pence.	Pence.
Ordinary bats-wing	10	4·3	2⅓	·142	·0142
Flat flame from	11·5	4·6	2½	·152	·0132
Flat flame to ...	13·8	4·6	3	·152	·0110
Flat flames in clusters	60	15	4	·495	·0083
	90	20	4½	·66	·0073
	150	30	5	·99	·0066
Special form (requiring motive power)	120	10	12	·33	·0028

On an average it may be assumed that each private lamp in London will be used for 1½ to 2 hours per day throughout the year, whilst in the suburbs it will be used 1 to 1½ hours per day. In shops open till nine o'clock, each lamp will be used three hours per day, and for public-houses, restaurants, etc., each lamp will be used four to five hours per day throughout the year.

The annual cost of gas would thus be in a private house with 30 lights used on an average 1½ hours a day, or 547 hours per annum:

	£	s.	d.
547 × 30 = 16,410 lamp hours at ·152d............... =	10	7	11
Add for rent of meter.......................................	0	14	0
Annual cost...	£11	1	11

The cost of gas-piping and ordinary (not ornamental) fittings may be taken as follows:

Workshops and factories	20s. to 25s. per light.
Shops	25s. to 35s. ,,
Private houses (with 20 to 40 lights)	30s. to 40s. ,,

It has been feared that gas properties will be injuriously affected by the general introduction of electric lighting, and that feeling has influenced some municipal authorities who own the gas works either to oppose electric lighting orders or to secure them with a view to their not being acted on. I think the apprehension of gas properties being injured is exaggerated. There is an increasing demand for gas for warming, for cooking, for motive power, and for other purposes, which makes it quite possible that the consumption of gas in the future may not be so diminished as is feared.

I will next give the result of my calculations and experience as to the cost of electricity. In a private house with 30 lights used on an average 1½ hours a day, or 547 hours per annum, the total lamp hours will be 16,410 per annum as before.

In order to compare with the estimate for gas previously given, a 12½ c.p. may be taken as the average for each lamp (some being 10 and the others 16 c.p.).

The actual cost of producing a Board of Trade unit of electricity may be taken at about 2½d., excluding the provision for the sinking fund, or 3¼d. per unit including that provision. At the rate of 3¼d. per unit the cost would be as follows:

·0135 × 12½ = ·169d. per lamp hour, including renewals.

	£	s.	d.
16,410 lamp hours at ·169d..........................	11	11	1
Add for rent of meter	0	14	0
Total	£12	5	1

If the current is charged at 6d. per unit (which is lower than most companies charge, and will yield a profit to the authority) the cost per candle-power per hour will be about ·022d. per lamp hour, or 0·275d. including renewals, in which latter case the cost of the 12-c.p. lamp would be £19. 10s. per annum, instead of £12. 5s. 1d.

For workshops and factories the cost of ordinary fittings for electric light will be from 25s. to 30s. per lamp.

Shops...................................	30s. to 40s. per lamp.
Private houses (with 20 to 40 lights)	35s. to 45s. ,,

There are several advantages in employing electricity instead of gas to which it is difficult to assign a money value. For instance, the whitewashing, painting, and papering of rooms would be seldom necessary when electric lighting is employed. The vitiation of the air by gas would be obviated, with good sanitary results, and the risks of fire would be diminished. In comparing the respective cost of gas and electricity the lamp hours are calculated as the same in both, whereas I think it will be found to be less with electric lights, as a light or series of lights are switched on and off so easily that it is found the light is more frequently turned off when it is not wanted than is the case with gas. Where delicate textile fabrics and decorative or artistic goods are exposed, it is found that the substitution of electric light for gas is attended with great advantage as regards their preservation, and also in enabling colours to be matched. Electric light is preferred to gas where wines, beer, etc., are stored, as it preserves the cellars and vaults cool.

I will next deal with public lighting, which concerns municipal authorities very closely.

For street lighting the arc light is the most economical. The smallest size of arc lamp at present manufactured requires a current of about five amperes, but for steadiness and efficiency it is desirable not to use less than six amperes. The candle-power of arc lamps varies considerably according to the angle at which it is measured. The greatest intensity with continuous-current lamps is found at an angle of about 40deg. below the horizontal line. The following table gives the approximate candle-power at various angles. The height of the lamps should be arranged so as to give an angle of not less than 7deg. to the most distant point which it is intended to serve.

LIGHTING POWER OF ARC LAMPS.

Current in amperes.	Horizontal	At angle of 7deg.	At angle of 10deg.	At angle of 20deg.	Maximum at angle of 40deg.
	c.p.	c.p.	c.p.	c.p.	c.p.
6	92	175	207	322	460
8	156	300	350	546	780
10	220	420	495	770	1,100

The following table gives the cost of working arc lamps:

Current in amperes	Average candle-power at angle of 20deg.	Watts required	Units used per hour.	Cost of current at 3½d. per unit.	Cost of carbons ·50 and fixing ·16	Total cost per lamp hour.	Cost per average candle-power per hour
				Pence.	Pence.	Pence.	Pence.
6	322	300	0·3	1·05	0·66	1·71	·00531
8	546	400	0·4	1·40	0·66	2·06	·00377
10	770	500	0·5	1·75	0·66	4·21	·00313

The last column in the table gives the cost per candle-power per hour, and these figures are arrived at by dividing the "total cost per lamp hour" by the figures representing candle-powers "at an angle of 20deg." (given in the table of lighting power) which represents a fair average of the power from arc lamps. The last column in the table of cost admits of comparison with the last column of the table previously given of the cost of gas.

Arc lights should be placed high up for the following reasons:

1. On account of their high candle-power and great distance apart.
2. Because the light thrown down at an angle is much greater than that cast horizontally.
3. Because the light given horizontally is not so steady as that which is thrown down at an angle.

The following data enable the coefficient of minimum lighting power in streets to be determined:

Let P = candle-power of lamps.
L = maximum distance from lamp in feet.
H = height of lamp in feet.
X = a coefficient.

The light falling on a unit area of pavement varies inversely as the square of the distance from the lamp, and is directly proportional to the angle at which it falls. This angle is nearly proportional to the height of the lamp divided by the distance. Therefore,

$$X = \frac{P}{L^2} \times \frac{H}{L}$$

or

$$X = \frac{PH}{L^3}.$$

The usual standard of gas lighting is represented by the amount of light falling on a unit area of pavement 50ft. away from a 12 c.p. gas lamp 9ft. high, which gives a coefficient as follows:

$$X = \frac{12 \times 9}{50^3} = \cdot 000864.$$

Adopting the above coefficient, I calculate that the before-mentioned sizes of arc lights will give the same standard of light at the heights and distances stated in Table A.

TABLE A.

Current in amperes.	Height of lamps. 20ft.	25ft.	30ft.	35ft.
	Maximum distances served from lamp in feet.			
6	160	175	190	202
8	185	202	220	235
10	205	225	243	260

Table B gives the corresponding distances, assuming the minimum standard to be doubled, thus bringing the coefficient up to ·001728, which represents the amount of light on a unit area 50ft. away from a 24 c.p. lamp 9ft. high.

TABLE B.

Current in amperes.	Height of lamps. 20ft.	25ft.	30ft.	35ft.
6	130	144	155	166
8	150	165	180	193
10	170	190	205	220

The distances the lamps are apart would, of course, be double the distances mentioned in Tables A and B.

One arc lamp will take the place of from three to six gas lamps, according to the locality, arrangement, and standard of light adopted.

A scheme of arc lighting, based on the substitution of one arc light on the average for 3½ to 4 gas lamps, would double the minimum standard of light, whilst the average standard would be increased 10 or 12 times.

Placing lamps along the middle of the streets has the advantage of illuminating the fronts of the houses more uniformly, and this advantage is more apparent when the lamps are of higher candle-power than that of the present gas lamps. Moreover, in business thoroughfares the footways are often fairly illuminated by the shoplights, whereas the middle of the road is thrown more into shadow.

The regulation of traffic in crowded thoroughfares would be much assisted by a well-considered system of large lights and shelters or refuges, and the cost of police control over traffic in streets likely to become congested would be reduced thereby, whilst the number of accidents would diminish.

A higher standard of street lighting appears to be inevitable in the near future, even if it is attended with increased cost. This is evidenced by the fact that authorities are now directing their attention to affording a much larger amount of light in main thoroughfares than has heretofore been accepted as sufficient.

In carrying out a system of public lighting by electricity, the fact that the lights can be instantaneously switched on and off at a central station may be taken into account. By having a second main and by connecting the lamps alternately to the two mains, every alternate light could be switched off at, say, midnight, and a saving effected in the *annual cost*. *It should be noticed that* with public gas lamps an appreciable time is taken up in the operation of lighting and extinguishing, by which the lamps that are first lighted and last extinguished have been consuming gas beyond the actual time that is needed for lighting purposes. A series of electric lights, on the other hand, admit of being switched on and off at the central station at the exact time required by the season, so that practically the number of lamp hours in the case of electric lights is less than with gas lights to the extent of several hundred lamp hours per annum.

It is not within the province of this paper to refer to the various methods for generating and distributing electricity. Municipal authorities have abundant practical data to enable them to be advised as to the introduction of the right system for electric supply in a district. This requires good judgment and a careful consideration of present requirements, having in view the possibility of future developments.

THE ELECTRIC LIGHTING OF PUBLIC BUILDINGS; WITH SPECIAL REFERENCE TO THE ATHENÆUM ELECTRIC LIGHT INSTALLATION.*

BY PROF. JAMIESON, M.INST.C.E., F.R.S.E.

Prof. Jamieson said that he would like to explain, by aid of sketches, etc., on the blackboard, how the various efficiencies given in Table IV. had been obtained.

1. *The electrical efficiency* of each dynamo was ascertained by running it at the normal speed (500 revolutions per minute), and noting simultaneously from the ammeter and the voltmeter the amperes, C_e, in the external circuit, and the potential difference or external E.M.F., E_e, with a constant load.
The product of these two quantities, viz., $C_e \times E_e$ = output in watts.
Having worked the dynamo at this output until the temperature of the various parts become constant, it was stopped, and the copper resistance of the armature between the brushes, R_a, the shunt magnet coils, R_s, and the main magnet coils, R_m, were taken *immediately* by a Wheatstone bridge and a Thomson deadbeat mirror galvanometer. From these resistances and the above values the current that had been flowing in the armature, C_a, and the total E.M.F. generated in the same, E_a, when the machine was working, were calculated as shown in the paper.
The product of these two quantities, $C_a \times E_a$ = total watts generated.

$$\text{Hence, electrical efficiency} = \frac{C_e \times E_e}{C_a \times E_a} = \frac{140 \times 113}{144 \cdot 2 \times 121 \cdot 36} = \cdot 904, \text{ or}$$

90·4 per cent. at *full* load for dynamos Nos. 2 and 4. As stated the efficiency of these two dynamos rises to 91·5 per cent. at about two thirds of full load, because then the temperatures, and consequently the resistances, of the armature and field magnet coils are not so great, or a less percentage of the total watts generated is transformed into heat at that output than at the maximum for which the machines were designed. The mean efficiency of the four dynamos at two-thirds load was thus found to be 88·5 per cent.

2. *The commercial efficiency* in the case of the Athenæum dynamos is also given as being equal to 88·5 per cent.; whereas, under ordinary circumstances, it should be less than the electrical efficiency. The brake horse-power was, however, taken with one engine coupled to its two dynamo armatures, but with the brushes lifted. Consequently, we could not eliminate the power required to drive the armatures *alone* at the normal speed of 500 revolutions per minute.

3. *The mechanical efficiency* of the engines was obtained by comparing the ratio of the brake horse-power to the sum of the indicated horse-powers of the three cylinders of the triple expansion engines when run at normal speed and load. The Crosby indicator was used for taking the diagrams.

4. *The commercial efficiency* of one engine and its two attached dynamos was found by multiplying cases 1 and 3, or 88·5 per cent. × 80 per cent. = 70·8 per cent.; because, owing to an accident to the indicator gear, we did not get a complete set of cards whilst measuring the electrical horse-power at the Athenæum by the ammeters and voltmeter. The simultaneous readings for electrical and indicated horse-powers of the new compound engines with the present dynamos will, however, be carefully ascertained when the engines have been fitted, and the results communicated to the institution.

5. *The theoretical efficiency of the engine.* This was ascertained by calculation from the indicated horse-power and the weight of steam used per indicated horse-power at known pressure and temperature.

6. *The commercial efficiency of the boilers.* This value was not ascertained, because it would have entailed not only a chemical analysis of the flue gases, but also their weight and temperature. The term commercial efficiency is used in different senses by different engineers. We, however, prefer to keep the term "commercial" for the ratio of the energy got out to the energy put in,

* Discussion on paper read before the Institution of Engineers and Shipbuilders in Scotland, *vide E.E.*, May 1, 8, 22, 1891.

and hence we have stated the "commercial efficiency of a boiler" to be the

$$\frac{\text{Heat units in steam generated from every pound of coal burned*}}{\text{Available heat units from every pound of coal burned}}.$$

This is an important quantity to be ascertained by the engineer, since it tells him the efficiency of a boiler as a means of transferring heat from the heated surfaces to the water.

7. *The theoretical efficiency of the boilers.* This quantity was ascertained in the following manner:

Steam at 145lb. absolute = 355deg. F., and absorbs 1,190 B.T.U. per pound when raised from water at 32deg. F.

But the feed-water was 145deg. F.; ∴ 145deg. - 32deg. = 113 deg. F.

Or, every pound of water had received 113 B.T.U before being introduced to the boilers.

∴ 1,190 B.T.U. - 113 B.T.U. = 1,077 B.T.U. *per pound* from water at 145deg. F. into steam at 355deg. F.

The coal used was only capable of converting 12·5lb. water at 212deg. F. into steam of 212deg. F., thereby absorbing 966 B.T.U. I arrived at this result from tests of the samples of the coal used by Thomson's calorimeter (as described at page 39 in Jamieson's "Text-book on Steam and Steam Engines," fifth edition).

But in the Athenæum boilers 6·8lb. of water were converted into steam at 145lb. absolute, by the combustion of each pound of coal.

Consequently, how many pounds of water would have been converted into steam from and at 212deg. F.?

$$966 \text{ B.T.U.} : 1{,}077 \text{ B.T.U} :: 6{\cdot}8\text{lb.} : x \text{ pounds.}$$
$$\therefore x = 7{\cdot}58\text{lb.}$$

From the above we can now deduce the efficiency of the boiler; for

$$12{\cdot}5\text{lb.} : 7{\cdot}58\text{lb.} :: 100 : y.$$
$$\therefore y = 60{\cdot}6 \text{ per cent.}$$

$$\text{Or, } \frac{\text{Heat units in steam generated per pound of coal}}{\text{Total heat units per pound of coal with perfect combustion}}$$
$$= \frac{7{\cdot}58}{12{\cdot}5} = {\cdot}606 = 60{\cdot}6 \text{ per cent.}$$

8. *Theoretical efficiency of the whole plant.*

Regarding the theoretical efficiency of the whole plant, see Table IV. We may check the result as follows:

Theoretical efficiency of boiler (60·6 per cent.) × theoretical efficiency of steam in the engines (7 per cent.) × the commercial efficiency of engines and dynamos (70·8 per cent.) = 3 per cent.

The **President** said they had heard Prof. Jamieson's explanatory remarks, and he now called for any further criticism.

Mr. Thom said he would confine himself to the mechanical arrangements. The author stated that, "Where the space is unlimited, then undoubtedly a slow-speed compound condensing engine of the Corliss or other quick and early cut-off type is to be preferred. Their efficiency is higher than that of any other class of engine." This was an assertion which must not be allowed to pass uncontradicted, as this antiquated theory of slow speed and early cut-off had done more than anything he knew to retard the advancement of the modern steam engine. The only point which could be claimed in its favour was the appearance of the indicator diagrams which had more beautiful expansion curves, and were therefore more suitable for showing the action of the steam in a cylinder theoretically. In practice the most economical engine was the quick-running compound or triple expansion, carrying the steam over half stroke, which gave less condensation in the cylinders. As theory always followed hard on the best practice, he had turned up the last book on the subject by Prof. Cotterill, and had found it stated "that low speed engines are less economical than high will be readily admitted," the reverse of which the author stated, and he pointed out that the condensation varied inversely as the square root of the revolutions, but they did not require to decide this question from a theoretical standpoint. The Admiralty found the engines so wasteful when working slow with an early cut-off that, when practical, they arranged two sets of engines on one shaft and only worked the one set when working at half power. He found from looking at the drawing of the boiler and connections that the arrangement had not had the consideration it deserved. Great care had been bestowed on making duplicate sets of pipes, but the part most likely to give trouble was common to both boilers, and instead of care being taken to save that part from fracture, there was stress put on it which it never was intended to take. He spoke of the connections between the steam receiver and the boilers. It would be noticed this was a rigid connection, but when steam was in the receiver it would lengthen, owing to the higher temperature about a quarter of an inch between the connections to the boilers. This had not been taken into account, so it was only a matter of time before the expansion and the contraction of the receiver broke this connection. He might say this arrangement would not be passed by the Board of Trade or Lloyd's surveyors. The receiver should be in halves, or connected to the boilers by flexible copper pipe, with bend or other arrangement of joint which would allow for expansion. He saw no reason why lives should not be guarded from obvious danger on land as well as at sea, and hoped to hear that this dangerous connection would be made safe for the attendants and others.

Prof. Jamieson: When I said "slow," I did not mean slow piston speed, but few number of revolutions per minute. I would keep high piston speed, but a good long stroke. First, in regard to the early cut-off engines, I may say as a matter of careful experiment that Mr. Ferranti, with small Corliss condensing engines at Deptford, obtained 13·5lb. of steam per hour per indicated horse-power. I know of no triple expansion engine that will beat that.

Mr. Thom: The triple expansion engines of s.s. "Iona," recently tested under ordinary working conditions by Prof. Kennedy and scientific staff, were found to use 13·35lb. per indicated horse-power per hour.

Prof. Jamieson said his experience had been that, given unlimited room and money, they were better off, taking everything into consideration (economy, freedom from breakdown, and expenses of upkeep), in the particular case of electric lighting, with simple, steam-jacketed, strong horizontal engines running at about 100 revolutions per minute, with a fair piston speed of, say, 400ft. per minute, having small clearance spaces and an early cut-off, than with *very* short-stroke high-speed engines, whether of the simple or compound type. More especially was this the case when they were far removed from the maker's works, and desired to employ an ordinary engineman instead of a highly-paid skilled mechanic. He had proved this to be the case in several instances. In regard to Mr. Thom's objections to the connections between the boilers and the steam dome, he had only to say that they had received due consideration from several points of view. Freedom faucet joints were employed, and, in addition, the stools upon which the boilers rested were made to a larger radius than the outside of the boilers, together with expansion hole in front smoke-box, so as to permit of free movement due to expansion or contraction of the steam dome. The original tender drawings, as well as the boilers, had been duly inspected and passed by the Boiler Insurance Company, of which Mr. Longridge, of Manchester, was the chief engineer.

Mr. Mavor: I think the institution owes its thanks to Prof. Jamieson for bringing this paper before it, but the paper as it stands is most disappointing and unsatisfactory, except when supplemented by the information which he gave this evening, and details of the boiler tests, which, we hope, he will be induced to produce. The question of high and low speed depends upon the size of the engine which you have to deal with. With a small engine, there is no doubt that the high speed is more economical than the low speed. The experience he spoke from was very accurate tests of different types of engines.

The **President**: I think it would clear the mind of many members present if you would speak of engines with high revolutions as compared with low revolutions. The engineering mind does not distinguish between engines with a great many revolutions and engines with fewer revolutions. It is the speed of the piston that we speak of when we refer to the speed of engines.

Mr Mavor said the state of matters was something like this, that where they had small machines they wanted to get an efficiency and the revolution as high as possible, and that tended to high revolutions to begin with. By using the engine coupled with the dynamo, they eliminated the trouble that was likely to arise from any gear whatever. That, he thought, there could be no dispute about, that an electrician in choosing a dynamo would choose an engine with high revolutions. When Prof. Jamieson said, "As the lamps get older, the carbon loops get thinner, and consequently their resistance increases, therefore we have to gradually increase the pressure to 115 volts as circumstances require," that method of procedure was utterly fatal to economical working. The condition of affairs in various instances might slightly modify the evil which this procedure brought about, but it would be evident that if the lamps began to increase in resistance and the pressure was increased accordingly, whenever they introduced new lamps, which were more valuable than old ones, intended to run at 110 volts, and they put in a pressure of 115 volts, it was proximate ruination. Of course the difficulty then arose that the lamps decreased in brilliancy, and the cure was to remove them as they increased in resistance, and replace them by new ones even before they broke down. It was just possible to get out of a lamp the life of 1,500 hours, but probably a life of 1,200 to 1,500 hours was a pretty economical one, especially as the cost in a year or two would be less. It was perfectly fatal to get the brilliancy out of old lamps. That was one important point. Then a statement was made to this effect: "A fair comparison has been made between the price that would be charged by any outside central lighting station at 8d. per B.T.U., and the actual cost to the Athenæum for generating the same by its own plant. It will thus be seen that for public institutions, etc., where there is a sufficient demand for light, a very considerable saving may be effected by running a private installation." Such calculations were extremely difficult to make without, at least, 12 months' experience of running. He found that Prof. Jamieson had got all the items in this calculation, and he had said that he had no objection to publish them in the *Transactions*, which would be found interesting. He might mention that while the cost in the Athenæum was 1·06d. per B.T.U. on a certain day in March for generating electricity, that was not by any means an unusual economy for such a load, and they had found frequently that they could reduce the cost in the following ratios. If they took a long day in winter, it would be found that the number of units generated brought down the cost to a very low point, in some cases as low as 2d. per unit, whereas in small runs it rose up to 11d. or 1s. Therefore, to take a single day was no guide to economy. The putting down of a lighting station was a most important one. It would be better for electric lighting if everyone had his own electrical manager, but he was very strongly of opinion—

* Just as it is customary to call the "commercial efficiency" of a dynamo

$$= \frac{\text{the electrical horse-power got out}}{\text{the brake horse-power put in}}.$$

and to his own loss he had held the opinion—that it was a great mistake for anyone in the centre of Glasgow to put down an electrical station with one or two exceptions. The only exceptions were the newspaper offices, where they would manufacture electric light cheaper than gas, and the railway stations and hotels, where the demand for light existed all day, and coal was obtained cheaper at these places. They could make it for 3½d. per unit. Mr. Preece, of the London Post Office, claimed to do it for 3½d. With such a case as the Athenæum, he was satisfied that, leaving out of consideration the enormous labour entailed in superintending the installation, and having an engineering manager in their place, the cost was out of all proportion to the advantage gained by so doing. There were one or two points of the general arrangement that he would like to call attention to. The drawing of the supply curve was very interesting, and the author said that it would show as favourably as any building that was not used during the night for putting in its own plant. At the same time, giving it the benefit of all that apparent advantage, he was quite satisfied that they would be much more comfortable and happy if they sold off their plant as soon as the town was able to supply them, and not increase it any further. Then with regard to the switchboard, it was a little difficult to follow it, but Prof. Jamieson was good enough to give him an explanation of it that day. There was the connecting switch. The purpose for which this switch was inserted was to prevent the dynamos from reversing on each other. It was his opinion, and open to discussion, that in such a case these machines ought not to be compound ones at all. They had in many cases compound dynamos for running parallel, and there was no object in having them parallel, because they required so much attention. Although a good deal had been said about compound winding, it seemed disadvantageous to divide the dynamos into four. One could not see the object of that, because with two properly constructed dynamos and one spare armature with a set of batteries the arrangement would be much simpler.

Mr. Couper said he was sorry that Prof. Jamieson did not give in his paper all the data which he had given since. The paper was a little difficult to discuss on that account, but there were one or two points he should like to take notice of. Under the heading, "General Arrangement of Plant," Prof. Jamieson said: "In installations of moderate dimensions, such as we have been considering, where space is of great moment, the engines, boilers, dynamos, etc., may be all placed with advantage in one room." He was inclined to think that such was not a good arrangement, and was one neither to be commended nor followed. In the Athenæum the engines and dynamos were placed close to the boilers and entirely unprotected, so that it was impossible to prevent the dust from the coal and ashes lodging on those very parts which should be protected, and kept free from grit. Everyone knew the amount of dust that gathered in a place where boilers were being fired, and if no other arrangement could have been made, surely a glass and wood partition could have been put up, shutting off the dynamos, engines, and switchboard from the rest of the space containing the boilers. It was all very well at first with a new start, but how about the tear and wear, and the renewal in course of time? As to the type of boilers used, he believed it was the one best suited for that and many other purposes. He just noticed the other day the report of a paper read on April 7 by Mr. R. E. Crompton before the Institution of Civil Engineers, in which the author stated that the space from front to back in electric light stations was generally so limited that boilers of short length and easily transported, and built in position, were best suited for this work. The boiler which occupied the least cubic space, and yet fulfilled the other requirements, was the one best adapted for situations like that of this installation. Space was limited, and generally so; it was a rare thing nowadays to find a public building where space was no object. The type his firm had supplied to the Athenæum was one that was easily accessible, and had its external surface visible at all times; it was not surrounded by brickwork, beneath which corrosion might be going on unknown. In regard to the receiver, to which one gentleman had taken exception, he might say they did not approve of its present arrangement. They suggested a connection by a copper bend pipe from each boiler, but Prof. Jamieson, as the consulting engineer, preferred a rigid connection, and went into the question of expansion to see what the amount would be, and satisfied himself with the arrangement. He also told them that he got the sanction of Mr. Longridge, and ultimately the connection was made as it then existed. So far, it had not given any trouble that he knew of.

Mr. Lindsay Burnet said that with regard to the mechanical engineering part of the paper, he would remark that it was generally found that the space was limited in public buildings, therefore, the slow-working flue boiler, having suitable heat-absorbing surface, was rather out of the question at ordinary working pressures, and to his mind would be entirely out of consideration for a pressure of 150lb. per square inch, such as was used in the present instance. Naturally, a slow working machine was more easily tended than a fast-working one; but he ventured to think that with the great variations of power required in cases like this, the fast working boiler, along with the higher intelligence of the attendants, would attain the highest commercial efficiency. One would have expected that a well known public teacher like Mr. Jamieson would have treated this part of the subject in more exact language than to speak of horse-power of boilers without defining that horse-power in some way. The Athenæum boilers might be 60 of that unknown ... if you coaled them to that extent; but from Table IV ... 'put, the heat efficiency was only 58·6 per cent. Of ... be (for the paper gave one no means of judging) that ... efficiency satisfied the whol... on for r... efficiency as referred to the ... t he w...

say that for a steam plant working only nine hours' full power ... of the 24, it was best to attain to 70 per cent., irrespective of first cost, so as to give the highest commercial effici... Regarding this low heat efficiency of 58·6 per cent., he would ... to state that with the grate area as used at the trial, which w... much as one-sixteenth of the total heating surface, it would req... great skill to prevent waste of fuel, and it would here be in... resting to know if the forced draught appliance was in use a... time. In the face of this, when it was remembered that b... efficiency, as usually stated, was a combination of the efficiencies ... the firemen, of the heating surface, and of the furnaces, as well ... of the fuel used, it was just possible that the efficiency of tr... mission through the given heating surface was really good: and ... course, this was the point for the boiler engineer when he had ... a free hand for the whole arrangement. In Table IV., Mr. Jam... gave, in item No. 6, a statement (without the value attached) of ... mercial efficiency which he (Mr. Burnet) considered quite mislead... and really useless to the steam user. It would be of great interest ... to know how a value was arrived at by Mr. Jamieson in making ... his complete statement of cost of light to the Athenæum ... prietors, as compared to equal light brought from a central stat... In the paragraph headed "Pipes and Flues," the statement ... made that "throttled passages check the flow of these ... (steam, water, or gases) in a most decided manner." T... reason why this well-known truth had impressed the co... sulting engineer of the Athenæum so much as it seemed ... have done, was that he decided at first to connect ... original small chimney by a wrought-iron box flue to ... new boilers, the result being that there was not suffic... draught to burn the fuel, and hence the blackest of black ... and little steam. A steam jet forced draught appliance was ... and did no good; only at last was a proper chimney erect... which appeared to give such excellent natural draught that ... practical men would wonder of what use was the steam jet. Let ... grate surface be made so that 20lb. of good coal be burned w... natural draught per square foot of fire grate, get an intelli... fireman who would regulate the fire with the chimney damper ... not by the fire-doors, as was mostly done at present; there w... then be abundance of steam with economy, and no more ... than at present. With reference to Mr. Jamieson's remarks ... the engines, he would say of them much as he had said in reg... to the boilers as concerned size and speed; and also that he had ... from engineers of experience in such matters, that commer... efficiency was attained best with subdivided power, just as adop... in the Athenæum. Undoubtedly it required men of high... intelligence to tend fast-steaming boilers and fast-running engines, and one could not (to take an extreme instance), expect a fa... labourer who now and again shoveled coal below an egg-end... boiler, to be able at once to keep steady steam in a fire engi... boiler, or in a Thorneycroft tubular torpedo boat boiler. Neve... theless, the higher intelligence could be procured, and should b... got and paid for, as it could easily be out of the saving effected.

Mr. M'Whirter said he was surprised at seeing Prof. Jamieson publishing such statements at they had in that paper. The infor... mation Prof. Jamieson had given rather cleared the ground; but ... would have been much easier and much better for the discussio... if the facts and figures put forward that evening had bee... embodied in the paper as published; particulars of tests we... always more valuable than the results. Results were alway... suspicious. This with all respect to Prof. Jamieson's standing ... he was sure that the author would be the very last to accept res... from anyone without the necessary data enabling these to be discussed. He (Mr. M'Whirter) wished to call attention to the factor ... efficiency. He quite agreed with the position the author took ... in regard to the difference between small high-speed engines an... larger engines running with slower revolutions. In the Athenæum it would have been impossible to have put in large Corliss engines which would no doubt have given good work and high efficiency. When it was remembered that such engines as those turned ... by Willans, running at 400 revolutions, and obtaining an electric horse-power for something like 18lb. of steam pressure—

Prof. Jamieson: More than that—28. An electrical hors... power would require fully more than 28lb. of feed-water per hou...

Mr. M'Whirter: If Prof. Jamieson would refer to the discussio... last year at the Institution of Electrical Engineers, he would ... it as he had stated. He referred to the discussion on Prof. Forbes' paper on electric lighting, etc. Here Prof. Forbes referred ... one firm in Berlin using Corliss engines, and working with ... consumpt of 15lb. of water per electrical horse-power. It wou... be a very good thing if they were to get the results of the forc... draught that Prof. Jamieson had used. This was something ne... and it would be a very good thing to get the steam results wi... and without it. From the author's remarks about the accumula... tors, and the defect of avoiding reversals, it appeared that he h... no E.M.F. cut-out in use.

Prof. Jamieson: We have that. It will be seen in the drawing.

Mr. M'Whirter: Coming to the dynamos, he did not at a... agree with the remarks of Mr. Mavor. He had no trouble wha... ever in using compound dynamos, either in working them singly ... coupled together; but at the same time it was necessary to ass... the regulation of compounding by means of a small rheost... inserted in the shunt circuit; the reason for this, which was w... known, being that, no matter how exact a dynamo might be ma... to compound immediately on starting work, the rise of temperatu... in the field magnet coils altered the relative values of the shunt a... series excitation, and lowered the permeability of the field magnet. As th... temperature increased, both tended to reduce the voltage ... the ... nals of the machine after having been run for some time. ... ound dynamos on the same circuit where accumulato... ere certainly troublesome, but thi... uld ...

easily guarded against. His firm used an arrangement whereby it was quite impossible to have the accumulators joined up to the main circuit at the same time as the dynamos. It was exceedingly simple and convenient. It was a pity the sizes upon dynamos were not marked, as the smallness of the scale made accurate measurements difficult. The first thing that would occur to electrical engineers was that the Athenæum dynamos appeared to be much too small for their work. He did not understand why such small machines were put in, and this impression was confirmed by the electrical data. Taking the revolutions as given, also the volts and the armature-turns, using Kapp's formula, then

$$K\,L = \frac{115}{500 \times 24{,}810^{-6}} = 1{,}200$$

useful lines in the magnet, and taking the magnet as 10in. diameter, then there would be 78·5 square inches, or a flux per square inch

$$= \frac{1{,}200}{78{\cdot}5} = 15{\cdot}3\,;$$

or, taking the leakage value as equal to 1·35 for this form of field, then the total flux per square inch 20·7 This was not only much above usual practice, but was higher than what has hitherto been taken as the theoretical limit of magnetisation, and showed that the watts expended in obtaining this very intense field were much too high; in other words, that the magnetisation was obtained at too high a price. This would be seen when they considered that the force required for magnetisation had to be increased from 4·6, with an induction of 16 lines per square inch, to 7·7, with an induction equal to 17 lines per square inch. Modern practice showed that very few dynamos were now made with a greater magnetic flux than 10 lines per square inch (useful). He (Mr. M'Whirter) had occasion to design a dynamo for almost exactly similar output. Instead of having 78·5in. of cross-section in the magnet, he had found that to get good work it was necessary to put in section equal to 117 square inches, and this dynamo had a drum armature, whereas the Athenæum machines were Gramme wound. Coming to the armature of the Athenæum dynamos, he found them in much the same condition as the field magnets namely, overloaded. The armature-turns were given as 248, and this multiplied by half the total current gave the load in ampere-turns:

$$248 \times 77 = 1{,}900 = \text{ampere-turns.}$$

(To be continued.)

CAMBRIDGE LIGHTING.

At a recent meeting of the Town Council, the debate on electric lighting was resumed.

A comprehensive report from the Electric Lighting Committee was placed in the hands of members of the Council, giving the entire history of the work of the committee since their first meeting on November 15, 1889. The proceedings included Dr. Fleming's report, which was before the committee on the 11th December, 1889; the arrangements made by the committee as to the employment and remuneration of Dr. Fleming; Dr. Fleming's reports of the 9th December, 1890, and 14th April last; and, lastly, the letters from Prof. Garnett to Mr. Finch, dated 14th April, 20th April, 25th April, 28th April, and 12th May last. These had reference to the system of electric lighting which has been carried out by Mr. Parsons in Newcastle-upon-Tyne, and which Prof. Garnett believed to be well adapted to the requirements of Cambridge. The letters also gave the results of the tests applied to Mr. Parsons's radial generator, with a view to arriving at the coal consumption. The committee presented all these documents for the consideration of the Council, and again recommended the adoption of the report of the 1st of May last.

Alderman Finch said the main question they had to consider that day was not whether the Council would adopt a system of electric lighting for public streets, because that question had been raised and distinctly decided on a former occasion, but what system they were prepared to proceed with? He would not ask the Council to definitely order the committee to adopt the system which was then under consideration, but he would put it in another shape, and ask them to authorise the committee to carry the scheme out. The committee came before the Council that day asking for authority. Surely it was high time, now that that question had been before the Council for so long a time, to take some definite steps. It was very desirable, as he said on Thursday last, that they should utilise the winter. If the winter was over before the electric light was established, they would not get that support from the customers which they would have if they had the light in the earlier part of the winter. He did not think he need bother the Council by going into the details of the question, because the documents which had been printed by order of the Council had been placed before the members of the Council. First of all, there was the report of the sub-committee who went to Newcastle; then they had the letters and the discussion raised by Dr. Fleming; the replies of Prof. Garnett and Mr. Parsons, and the subsequent letters of Prof. Garnett. The committee found that the works at Newcastle, where the turbine engines were in use, had been able to give a certain substantial result, and that business had been carried on at a profit. Therefore, even those engines, imperfect as they were, speaking in the light of present improvements, were satisfactory for the purposes to which they were applied. If they were satisfactory, that was to say, in regard to yielding profits, then they had one substantial fact on they could proceed with their work in Cambridge. He did not know whether the committee would, even if they were advised by the Corporation, adopt precisely the same machines that were in use at the works at Newcastle, because there was undoubtedly a great deal of difference in the price of coal at Newcastle and Cambridge, and what would very well pay at Newcastle would not necessarily pay in Cambridge. But they were shown a new form of turbine, which would effect very great economy. An experiment had been made upon the new machine, and the result went to show this: that it was more efficient than those in use at Newcastle, and it required 60 per cent. less fuel to do the same amount of work. Therefore, if they could make a profit at Newcastle, they could make a profit at Cambridge. They were not, as had been charged against the committee, taking upon themselves the duties of experts. No man sitting round those tables who was about to take up that question would say he was an expert; he would ask for certain facts, make enquiries what the outlay and revenue was likely to be, would see the different kinds of machinery in use, and the result would be that a man of business would be in a position to form a judgment as to whether he would or would not adopt a system. The committee and sub-committee had been doing something of that kind. It had been suggested that there was only one opinion amongst engineers with regard to that invention, and that opinion was adverse. He had with him one of the volumes of the *Proceedings* of the Institution of Mechanical Engineers in August and October, 1888, when Mr. Parsons read a paper describing the turbines which are now in use at Newcastle. There was one chorus of praise from beginning to end. After reading extracts from the speeches of several men of eminence in favour of the scheme, Alderman Finch said if it was true that there was only one opinion upon that matter, they then knew from an authoritative source what that opinion was. He did not think he need go any further into the merits of the scheme. The sub-committee who went to Newcastle was composed of men who were very fairly representative of the Council. They were shown figures similar to those sent to the Board of Trade as to their capital, the balance-sheets and the monthly pay-sheets, and as the Council could not go and look at those documents for themselves, they asked them to say that they would believe those men of business, and study the statements that had been made. He contended that the paragraph in the report which had been criticised by an electrical journal had been abundantly verified, inasmuch as instead of there being a gain of 35 per cent. there was a gain of nearly 50 per cent. What they asked them to do was to authorise the committee to proceed on the lines of their report. If they agreed to that, they would be asked to appoint Prof. Garnet as electrical engineer on the terms which he addressed to the town clerk, and which the committee thought very reasonable, and then they would be asked, further, to authorise the Electric Lighting Committee to proceed up to a certain amount of expenditure. He then proposed "That the committee be authorised to proceed on the lines of their report."

Councillor Scott seconded the motion.

Councillor Dr. Porter said he felt very sorry that he found it necessary to move an amendment, and make some remarks upon the report of the committee. The first point he would like to refer to was the position of Dr. Fleming, who was one of the highest authorities on electric engineering. Dr. Porter had read a copy of a letter forwarded to Dr. Fleming by the town clerk, which he said made it clear that Dr. Fleming had been appointed by the Council. He contended that the committee had no right to dismiss an officer appointed by the Council, and asked for Dr. Fleming to be reinstated as professional adviser to the Corporation. If the committee dismissed an engineer simply because he expressed opinions which did not coincide with their own, he did not see the use of an expert at all. He would like to make one or two remarks upon the report of the Electric Lighting Sub-Committee, which was adopted by the Electric Lighting Committee. The most important question for the Town Council to consider was, he thought, would the working be remunerative? Alderman Finch referred to the accounts kept at Newcastle, and mentioned the profits they might expect if that system was adopted. It seemed that the balance for the half-year was £843. Dr. Porter then referred to what he considered to be two most important omissions from the accounts—namely, interest on the capital expended and repairs and renewal of the machinery. If those items were allowed, the profits would be £65, and if they deducted a further sum for extra cost of coals they would have their profit of £843 converted into a loss of £400. He thought from that statement it was quite clear that the works at Newcastle afforded no satisfactory basis for them to work a similar system with any chance of making any profit whatsoever. He next quoted statements from the report of the sub-committee, with a view of showing that twice the amount of steam was required to work the turbine system that was necessary for working other systems with an ordinary engine, and read extracts from a letter from Messrs. Willans, objecting to misleading statements in the report as to the consumption of steam in the Parsons turbine and the Willans engine. It was stated in the report that in the new form of Parsons turbine, a saving of 35 per cent. would be effected, and Mr. Alderman Finch in his speech had advanced this saving to 50 per cent. Prof. Garnett's reports rested far too much, like that of the committee, on hypothesis. Why were not the experiments conducted on the new installation at Scotland Yard, and all hypothetical statements got rid of? He stated that an experiment conducted on the electric installation at Peterhouse, under the superintendence of the Demonstrator of the Engineering

Laboratory, showed that the consumption of coal per unit generated was 8·5lb. He thought the only justification for the Town Council undertaking any system of electric lighting was to make a profit for the relief of the rates. If they could not show clearly that they could make a profit, then it would be quite wrong for the Council to undertake a scheme which might involve the ratepayers in a great loss. He moved in substance that the report be amended, by referring the question of the efficiency of the Parsons turbine as a motor to Mr. Kennedy, M.I.C.E., and that Dr. Fleming be reappointed professional adviser to the Corporation.

Councillor Vinter: May I ask the question whether Dr. Fleming was appointed by this Council?

The **Town Clerk**: No, sir; he was not.

Councillor Vinter: Then Dr. Porter's contention entirely falls to the ground.

Councillor Dr. Porter then read a portion of the town clerk's letter to Dr. Fleming, which was as follows: "I have to inform you that the terms stated in your letter describing the scope of your duties in regard to the electric light in the town were approved by the Electric Lighting Committee, and upon their recommendation have been sanctioned by the Council, subject to a slight alteration in paragraph B."

Councillor Vinter: That, surely, is no appointment by the Council.

Alderman Cockerell seconded the amendment, mainly because he thought the matter required further consideration, and that they ought to receive further advice before they proceeded with any scheme. If they did as Alderman Finch asked them to do, they would be committing themselves irrevocably to that particular scheme. He thought the matter was one of such great importance to the town that they could not do better than have further advice before taking further proceedings in that matter. As to whether Dr. Fleming was appointed by the Council, he was surprised to hear the suggestion that he was not. He distinctly remembered the committee making a report to the Council, and the Council confirmed that report. If that was not an appointment by the Council he would like to know what was.

Councillor Vinter differed with Alderman Cockerell, and said it was not a question for further consideration at all. It was a question of the disposal of the electric light for Cambridge by the Town Council, and if the recommendation of the committee was thrown out that morning, he thought they would have a very great deal of difficulty in finding a committee who would labour for the electric light as they had done for years past. First of all, he contended that Dr. Fleming himself had practically resigned—he never was appointed by the Council at all. After that they could not place any confidence in him as a practical man. Dr. Porter laid stress upon the balance-sheet prepared at Newcastle, from which he argued that there would be a loss if the system was adopted in Cambridge. But Dr. Porter might have looked a little further, and told the case fairly. Dr. Porter assumed that the price of the electric light in Cambridge was going to be the same as in Newcastle, whereas it was going to be 25 per cent. more, which made a difference of £1,200 per annum. He thought Dr. Porter ought not to have omitted such an important fact. The reasons Prof. Garnett expressed himself in favour of the scheme were, first, the small cost of the machinery, and then he went on into details about the buildings and the efficiency of the scheme. Now, if the cost of the machine be one-third less than that recommended by Dr. Fleming, and the efficiency was the same, it could not possibly be contended that they were advocating the cheapest thing simply because it was the cheapest. He was sure that every member of the committee was perfectly satisfied that that was the best scheme. There was only one member who differed as to the report, and he not upon the principle: he thought it would be better in the hands of a company than in the hands of the Corporation. They had the unanimous report of the committee, and he hoped that they would support it. If the Council were going to undertake the work, they ought to do it at once. Their provisional order would run out next July, and they ought not to lose the chance of taking the matter up. He thought that past experience showed that if the Council had been wise in taking up the work of the water and gas companies—and he went further, and said the tramways—they would be very much better off than they were.

Councillor Burford expressed a hope that the amendment would be accepted. They had the ratepayers to study, and he maintained that they, as a corporate body, ought not to enter into any commercial speculation unless they could make it pay. They were in no particular hurry for the electric light; they could wait a little while. He thought it would be a great deal better—there would be less expense and risk—if a company took the matter up. He did not know they had individuals who could carry out that matter better than they could in London. They did not find any corporation or vestry having taken the matter up in London, and he thought that with one exception public bodies were like London. If they went to Birmingham, they found the Council in a similar position to themselves. They found, after a great deal of discussion, it would be much wiser and less expense to the ratepayers if a private company took the matter up. He felt certain that the adoption of the electric light by the Council would mean increased rates. If they borrowed £30,000 or £40,000 it must mean an increase in the rates. He felt certain that if they promoted that scheme they would have increased rates, but if they threw the responsibility on an individual or company they could get what they asked for. It was too serious a matter to enter into that scheme hastily. They had had some splendid reports, but when Dr. Fleming [illegible] the scheme he found it to be a failure. He said that [illegible] *ought not to have been dismissed.* Dr. Fleming was [a con]scientious man, and too conscientious to allow the Corporation [to] be dragged into a thing which he thought would not pay. [He] wanted the electric light—it was a splendid thing—but he thought they ought not to spend the ratepayers' money when they would not receive benefit. He knew there was a strong feeling that it would be a good thing if the matter was in the hands of a company.

Councillor E. C. Young thought they had already settled the question some time since that they intended to carry that work out. Were they discussing that morning whether they were to have the electric light or not? He understood they had already agreed to undertake the electric light, and the only point they had to consider was, which was the best method of carrying it into execution. On the advice of Dr. Fleming, a scheme was submitted to them which they thought would pay, both financially and as far as the lighting was concerned. To their surprise they discovered, as time went on, that instead of that being the case, the initial costs were so great that the committee must of necessity stay their hand. A sub-committee was appointed to consider whether some more excellent way might not be devised for executing what was the intention of the Council. The sub-committee visited Newcastle and Bradford, and came back with a report strongly advocating the adoption of Mr. Parsons's system. They had not dismissed Dr. Fleming; he said Dr. Fleming had practically withdrawn from the situation. When the matter was submitted to Dr. Fleming, he distinctly said he could not recommend the system of Mr. Parsons; and they, on the other hand, could not accept Dr. Fleming's scheme because the costs were so great. The question was whether they should or not adopt the system of Mr. Parsons, which, in contradistinction to Dr. Fleming, they believed could be worked at a profit. He did not expect much profit for the first year or two—no one who started a new venture expected that; but when he looked at the fact that the light would be all over the town in 10 or 15 years' time, he thought that those who found the money for the undertaking would receive profit from it. In the case of the water and gas companies, the people all over the town were obliged to have water, and in many cases they were obliged to have gas, and the shareholders reaped the benefit; but if, on the other hand, the Corporation undertook the management of those concerns, the ratepayers would have received the benefit. That was the reason why he had always advocated that those concerns should be in the hands of the Corporation.

Councillor Dr. Kenny observed that Councillor Young seemed to forget that the inhabitants of the town were under no obligation to have the electric light. Their experience had been very much enlarged in more than one direction since they first formed the idea of applying to the Local Government Board in reference to that matter. What had they there that day in that report? They had a record of the changes and experiences of the committee. It was not very long ago that a scheme was to have been carried out by Dr. Fleming. That was put to the test of experience by the opponents of the scheme and collapsed. Then the committee brought forward another scheme, which looked equally well upon paper. That was submitted to the onslaught of Dr. Fleming, and that again collapsed, and the consequence was Dr. Fleming collapsed also. He (Councillor Dr. Kenny) was contending that day that they were entitled even at that stage to consider whether or not it was desirable that the Corporation should undertake that work. Councillor Burford had told them that his increasing experience of the work of the Corporation had led him steadily to believe that it would be unwise for the Corporation to undertake extra duties. He confessed exactly the same. He was in a position of doubt when he first came into the Council, but his increasing experience of the burdens on the shoulders of the Corporation led him to think that they were not a body sufficiently numerous, and had sufficient leisure to be able to take upon their shoulders an extremely important commercial undertaking. He felt that the more because that undertaking involved a capital expenditure of not less than £27,000. That might be a fleabite to some Corporations, but they were to take it upon their shoulders when they had a great sewage scheme which they could not possibly put off. For those reasons he hoped they would pause before it was too late, and resign that important undertaking to private enterprise.

Councillor Whibley said that with reference to the question which had been raised as to whether the scheme should be undertaken by a Corporation or a private company, he felt very strongly that it should be in the hands of the Corporation.

Councillor Bond said that as electricity was comparatively a new science, and improvements took place every year, it was just possible that after the committee had been at work sometime, they would find a more excellent scheme than they had at present. He thought they were very much indebted to Dr. Porter for pointing out that they ought not to undertake works of that sort unless they would be remunerative. He (Councillor Bond) would rather say, unless the town were safe from losing money. If the committee were going to carry out that scheme, had they made up their minds that the town would not incur a loss? If they did not carry that report, of course the committee would resign. Where were they going to get another committee? He thought it would be better if a private company were allowed to carry the scheme out; but under the circumstances he had come to the conclusion that they would be able to make it pay, and the town would not be involved in a loss. He did not feel disposed after the hard work the committee had done to oppose the motion.

Alderman Finch pointed out that if he shared the anxiety shown by several members of the Council as to whether the undertaking would pay, he would not make the proposal he had done. He was confi[dent] that the scheme would be made to pay. With regard to D[r. Fleming], when he arrived at that conclusion which

had been stated, there was not a single member of the committee prepared to go on with his scheme. He contended that Dr. Porter had formed his opinion on narrow premises, and concluded by stating that the committee believed that the scheme would pay its way.

On the amendment being put to the meeting, 10 voted for it and 19 against. The motion was then agreed to.

On the motion of **Alderman Finch**, seconded by **Councillor Vinter**, it was decided to appoint Prof. W. Garnett electrical engineer for carrying out the scheme.

It was also decided: "That in the event of their report of 1st May being adopted by the Council, they be authorised to conclude contracts for the carrying out of the electric lighting of the town on the general lines of that report, it being understood that the total cost shall not exceed £26,500, and that the installation shall suffice for 5,000 lights of 16 c.p. or their equivalent."

COMPANIES' MEETINGS.

CITY AND SOUTH LONDON RAILWAY.

The adjourned general meeting of this Company, to consider the question of raising further capital, was held on Tuesday at Winchester House, Mr. G. C. Mott (chairman) presiding. A report of the proceedings which gave rise to this adjournment will be found in our issue for June 19.

The **Chairman** said they would remember that at the meeting held on June 16 it was agreed that in the interval the Directors should have a conference with some of the larger shareholders of the Company to see whether any method could be devised for raising the additional capital in a better and more economical way than had been proposed. That conference had been held, and the matter had been very fully and carefully discussed; and in the result it was agreed by all of them, he thought, that the recommendation made to them by the Directors was the best and most economical way of raising the money. It was proposed to slightly modify the resolution, and this quite met the view of the Directors themselves—namely, that although they created £150,000 of preference shares, they should be authorised at the present moment to issue only 5,000 of them—that was £50,000. It had also been thought desirable that the preference shares should carry with them the ordinary voting power, the same as the ordinary shareholders had. He concluded by proposing: "That the resolution passed at the general meeting of the Company, held on August 12th, 1890, relating to the creation of the new capital authorised by the City and South London Railway Act, 1890, be, and the same is hereby, cancelled and annulled, except as to the creation or issue of 5,000 ordinary shares of £10 each, part of the total number of 20,000 shares authorised by the said resolution." This was simply cancelling what they did nearly a year ago in creating all the balance as ordinary capital. They must cancel this before they could create the preference shares.

The motion was seconded by **Mr. S. Hanbury**, and carried unanimously.

The **Chairman** then proposed the following resolution: "That £150,000 of the share capital, being the balance of the £200,000 authorised to be created by the City and South London Railway Act, 1890, be, and the same is hereby, created in 15,000 preference shares of £10 each, bearing interest at the rate of £5 per cent. per annum, and that the Directors be, and that they are hereby, authorised to issue 5,000 of such preference shares, in such amounts, at such times, and on such terms and conditions as they may think fit. The holders of the preference shares hereby created shall be entitled to vote on the same scale of voting as the holders of ordinary shares."

Mr. Hanbury seconded the resolution.

A **Shareholder** asked whether the interest was cumulative.

The **Chairman** said that they could not make it cumulative under their Act. The shares were, in fact, ordinary shares, having a priority as regarded interest. They must remember that the amount of preference capital they created was very small in proportion to the ordinary capital—much smaller than in the case of any other railway company.

The resolution was carried unanimously.

COMPANIES' REPORTS.

NATIONAL TELEPHONE COMPANY.

The report of the Directors for the year ending April 30 states that there is a balance to the credit of net revenue account of £194,821. 8s. 1d., after providing, among other charges, for the expenses of issuing new debenture stock, and the accrued interest thereon to April 30, 1891. Of this amount the sum of £62,973 has been absorbed by the payment of an interim dividend on the preference shares at the rate of 6 per cent. per annum, and on the ordinary shares at the rate of 5 per cent. per annum for the first six months of the year. The Directors propose to pay a further dividend on the preference shares at the rate of 6 per cent. per annum, and on the ordinary shares at the rate of 7 per cent. per annum for the last half of the year, which will absorb a further sum of £86,365. 19s., leaving a balance of £45,482. 9s. 1d. Out of this amount they propose, under article 113 of the articles of association, to transfer to reserve account £40,000, bringing up the amount of the reserve fund to £93,500. There will then remain £5,482. 9s. 1d. to be carried forward to next year. The extension of the Company's business during the last year has been so large that notwithstanding the heavy reduction of rates which the Directors thought it wise to make in the provinces, in view of the expiration of some of the Company's most important patents, the gross revenue, which last year stood at £411,114. 14s. 1d., reached £418,560. 7s. 8d. on April 30, 1891, and is still steadily increasing. The number of exchange and private line subscribers over the whole of the Company's system, including the South of England district, which last year was 29,257, was on April 30, 1891, 35,440, an increase of 6,183 subscribers during the year, and the number of subscribers is still increasing. The Directors are still acting upon the conviction that it is of vital importance to continue the policy of developing and improving the Company's system, and of giving greater facilities to the public. The accrued rental for the year ending April 30, 1890, was £363,704. 17s. 5d. For the present year it is £422,378. 6s. 2d. The working expenses for the year ending April 30, 1890, amounted to £148,457. 0s. 9d., being 40·7 per cent. on the accrued rental, whilst the working expenses of this year amount to £184,056. 9s. 6d., being at the rate of 43·5 per cent. on the accrued rental. The Directors have taken over the business of the South of England Telephone Company, Limited, which is now merged in this Company. On the amalgamation, in July, 1889, of the three principal companies, it was thought desirable that the customary annual retirement of one-third of the Directors should not take place at the end of the first year, in order that the numerous arrangements rendered necessary by the amalgamation and reorganisation of the Company might not be interfered with. These having been now completed, and two of the provincial companies—the Northern and South of England Telephone Companies—having been absorbed, the Directors think they ought all, at this meeting, to place their offices at the disposal of the shareholders, and submit themselves for their approval. They, therefore, now all retire, and being eligible, offer themselves for re-election. The auditors, Messrs. Welton, Jones, and Co., retire, and are eligible for re-election.

NEW COMPANIES REGISTERED.

Babcock and Wilcox, Limited.—Registered by Hollams, Sons, Coward, and Hawksley, Mincing lane, E.C., with a capital of £240,000 in 10,000 preference shares of £10 each and 14,000 ordinary shares of £10 each. Object: to acquire the undertaking heretofore carried on in London, Glasgow, and elsewhere, other than in the United States of America and the Island of Cuba, by the Babcock and Wilcox Company of New York, in accordance with an agreement expressed to be made between the Babcock and Wilcox Company of New York of the one part and the Company of the other part, and to carry on business as manufacturers of water-tube steam boilers, and generally the business of engineers and manufacturers of machinery of every description. The first subscribers are:

	Shares.
C. A. Knight, 114, Newgate-street, E.C.	1
W. Shaw, Upper Highlever-road, North Kensington	1
H. P. Smith, 1, Farley-terrace, Wilna-road, Earlsfield	1
J. E. Slack, 24, Parkhurst-road, Holloway, N.	1
W. Reavell, 114, Newgate-street, E.C.	1
R. Maurice, 114, Newgate-street, E.C.	1
E. Stinton, 114, Newgate-street, E.C.	1

There shall not be less than three nor more than seven Directors. The first are Andrew Stuart, Sir William Arrol, Arthur Telford Simpson, J. G. Mair Rumley, Charles Albert Knight, James Hermann Rosenthall, and Henry Faustin Knight. Qualification, £2,000. Remuneration, £2,000, divisible.

Bournemouth Lighting Company.—With a capital of £50,000 in shares of £5 each, the Bournemouth and District Electric Supply Company, Limited, has been formed to undertake the supply of electric light and power in Bournemouth, and for that purpose to take over the central station, business, and undertaking, under provisional orders, of the Brush Electrical Engineering Company in Bournemouth. The arrangements under which the Company is to acquire the undertaking and property provide for the payment of £17,275, at the option of the Company, either wholly in cash or in shares, or partly in cash and partly in shares. A minimum dividend, at the rate of 5 per cent. per annum, upon the paid-up capital is guaranteed by the Brush Company for the first three years.

Gloucester Electricity Supply Company, Limited.—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100 in £1 shares. Object: to carry on business as electrical engineers, electricians, etc.

Middlesbrough Electricity Supply Company, Limited.—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100 in £1 shares. Object: to carry on generally the business of electrical and mechanical engineers, etc.

Queen Anne's-mansions Lighting and Heating Company, Limited.—This Company has been formed, with a share capital of £60,000 in 3,000 four and a half per cent. cumulative preference shares of £10 each and 3,000 ordinary shares of £10 each, for the purpose of taking over and working a contract for the heating and supplying electric light and hydraulic power to Queen Anne's-mansions and other houses and buildings in the neighbourhood.

and for the distribution and purification of the water supply thereto, together with a lease of the basement of the premises.

Rochdale Electricity Supply Company, Limited.—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100 in £1 shares. The objects of this Company are sufficiently indicated by the title.

Stoke-on-Trent Electricity Supply Company, Limited.—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100 in £1 shares. Object: to carry on the business of an electrical engineer in all its branches.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts for last week were £5,653.

Eastern Extension Telegraph Company.—The Company has declared an interim dividend for the quarter ended March 31 last of 2s. 6d. per share, payable on the 15th inst.

Bell's Asbestos Company.—The Directors have declared an interim dividend of 2s. 6d. per share, free of income tax, for the half-year ended June 30, being at the rate of 5 per cent. per annum.

City and South London Railway.—The receipts for the week ending 27th inst. were £697, against £721 for the preceding week. The total receipts for the four weeks ending June 27 were £3,054.

Western and Brazilian Telegraph Company.—The receipts for the week ended June 26, after deducting 17 per cent. of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £3,833.

St. James's Electric Lighting Company.—An interim dividend at the rate of 7 per cent. per annum has been declared on the ordinary shares for the half-year ending June 30th. The transfer books will be closed from July 1st to July 10th, both days inclusive.

Young v. The American Telephone Company. On the application of two of the defendants in this case (the American Telephone Company and Mr. Mason, the president of the Company) Mr. Justice Kekewich last week stayed all further proceedings in the action on the ground that they were frivolous and vexatious, and that the matter had been disposed of in two previous actions.

PROVISIONAL PATENTS, 1891.

JUNE 22.

10612. **Electrical transformers for rotary-phase currents.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, London. (Siemens and Halske, Germany.)

10613. **Glow lamps for rotary-phase currents.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, London. (Siemens and Halske, Germany.)

JUNE 23.

10636. **Improvements in electric telegraph printing.** Marshall Arthur Wier, Fairview, Kingston-on-Thames.

10664. **Improvements in or connected with the insulation of electrical conductors.** Herbert Tom Harris, 433, Strand, London.

10697. **An improved method of and apparatus for protecting dynamo-electric generators and other apparatus from the effects of lightning.** Henry Harris Lake, 45, Southampton-buildings, London. (The Thomson-Houston International Electric Company, United States.) (Complete specification.)

10703. **Improvements in the manufacture of the arms or attachments of telegraph poles for carrying insulators.** Howard Cochrane Jobson, 7, Staple-inn, London.

10704. **Electric directing apparatus for use in cabs, carriages, or on boats, railway trains, and the like.** Arthur Douglass, 13, Southampton-street, Pentonville Hill, London.

JUNE 24.

10729. **Dynamo or electromotor ring armature construction.** Gilbert Betteley Luckhoff and Emil Henri Hungerbuhler, 214, Whitehorse-road, Croydon, London.

10762. **Improvements in call boxes or like electrical communicators.** George Thomas Cashmore, 6, Livery-street, Birmingham.

10778. **Improvements in electric arrangements and apparatus for locking railway signal and point levers, also applicable for other purposes.** John Audley Frederick Aspinall and Henry Albert Hoy, 45, Southampton-buildings, London.

10787. **Improvements in materials for insulating electric conducting wires, and for carbons and incandescent filaments for electric lighting.** Gustave Adolphe Cannot, 35, Southampton-buildings, London.

JUNE 25.

10822. **A compound preparation to be used as a substitute for guttapercha and similar products for insulating and waterproofing purposes.** Charles Napier Jackson, 64, *Hanley-road, Hornsey Rise,* London.

10821. **Improvements in firing guns by electricity.** W
Balch, 17, Queen's-road, Chelsea, London.

10832. **Improvements in electrical transformers.** Wo
and Rawson United, Limited, 88, Queen Victoria
London. (Ernest Preschlin, Germany.)

10838. **Improvements relating to the lighting of tra
electricity.** William Brew, 4, South-street, Fi
London.

10839. **Improvements relating to dynamo-electric ma
and to electromotors.** William Brew, 4, South
Finsbury, London.

10843. **Improvements in apparatus for regulating e
currents.** Jules Ferrand, 46, Lincoln's-inn-fields, L

10860. **Improvements in means or mechanism for reg
the lighting intensity of electric lamps.** Robert
Spreadbury, 37, Chancery-lane, London.

JUNE 26.

10877. **Improvements in or connected with means of con
ropes or cords, and hauling electric or other**
Arthur Annesley Voysey, 15, Water-street, Liverpool

10887. **An apparatus for lighting by electricity large nu
of gas burners simultaneously and cheaply, as com
with existing methods.** James Walker and Joseph
shire, 2, Union-street, Dewsbury.

10894. **Electrometers.** Charles Vernon Boys, 11, Ale
square, London.

10932. **Improvements in apparatus for repairing commu
of dynamos** Arthur Bernard Gill, Shirley Hous
Avenue, Grove Park, Lee.

10933. **Improvements in commutators of dynamo-e
machines.** Arthur Bernard Gill, Shirley Hous
Avenue, Grove Park, Lee.

10934. **Improvements in dynamo-electric machinery,
the regulation thereof.** John Augustine Kingd
Arthur Bernard Gill, 29, Marlborough-hill, London.

JUNE 27.

10939. **Improvements in conductors for electric lighting,
bell circuits, and like purposes.** Henry Alexander
William Arthur Coulson, and Sam Mavor, 62, St. V
street, Glasgow.

10969. **Dynamo-electric machines.** William Aldred, 5,
side Bank, Sheffield.

10977. **Improvements in galvanic batteries.** Auguste d
tens, 47, Lincoln's-inn-fields, London. (Date appl
under Patents Act 1883, Section 103, 28th Novembe
being date of application in France.)

10978. **Improvements in insoluble porous anodes for
lytical processes.** Siemens Bros. and Co., Limit
Southampton-buildings, London. (Siemens and
Germany.)

10983. **The electro-medication belt or pad.** John Henry
son and The Aurophone Company, Limited, 21, E
square, London.

11004. **Improvements in and relating to the manufac
plates for electric accumulators.** Constant Rous
Southampton-buildings, London.

NOTES.

Dr. Louis Duncan, of Johns Hopkins University, has sailed from America for England.

Royalty and Science.—Prince George of Greece visited Edison's laboratory last week.

Carlsbad.—On Thursday, last week, the town of Carlsbad was lighted by electricity for the first time.

Mica.—An extensive deposit of mica, so largely used for insulating purposes, has been discovered at Mario, North Carolina.

Water Power in California.—In a few months Yreka, California, will be lighted by electricity obtained from water power.

Silent Engine.—Why was the gas engine used in a certain testing institution not a hundred miles from Charing Cross, called a "silent" gas engine?

Balloon Struck.—The balloon recently imported to the Chicago Exhibition was struck by lightning on Monday, and the two aeronauts were severely injured.

Electric Drilling.—An Edison electric drill has recently demonstrated its utility by drilling a 2in. hole through 20ft. of solid granite in four hours.

Bootle.—The Finance Committee of the Bootle Town Council thinks that they ought to have the electric light as soon as possible. They have two boilers but no engines.

Exhibition at Paris.—The exposition which opens in the Palais d'Industrie on the 23rd of this month at Paris promises to have some interesting electrical exhibits.

Electric Carriage.—Chas. Reitz, of Indianapolis, has built an electric carriage driven by a motor and 30 cells, which will be shortly on the streets. The outfit weighs 500lb., and runs 8 to 10 hours.

Institution Laboratories.—The Belgian Société des Electriciens have in contemplation the establishment of an electrical laboratory similar to that of the Société Internationale des Electriciens at Paris.

The Telautograph.—The writing telegraph was tested on June 21st over 1,030 miles of ordinary telegraph line, and a number of messages were sent (by an expert of their own) successfully over this distance.

Morley.—At the meeting of the Morley Town Council, on Monday, it was resolved that the Council would be prepared to receive estimates as to the cost of establishing and carrying on a supply of electric light within the borough.

Railway Dynamos Struck.—Four of the dynamos at the power-house of the electric street railway at Richmond, Virginia, were recently struck by lightning and the armatures destroyed. Several cars were also struck, but no one was injured.

York.—The new municipal buildings in York, just opened, are lighted throughout with gas, but electric light wires have been laid through the whole building, so that the electric light can be introduced as soon as an installation is provided in the city.

Development of Telegraphy.—An interesting paper was read before the Canadian Society of Civil Engineers by Mr. D. H. Keeley, of Ottawa, on "Developments in Telegraphy—Wires Multiplexed and Interchangeable," published in pamphlet form.

Royal Society of Edinburgh.—At the meeting of the Scottish Royal Society, on Monday, communications were presented by Prof. Knott on "The Electric Resistance of Cobalt at High Temperature" and "The Thermo-electric Position of Cobalt and Bismuth."

Parliamentary Powers.—Petitions have been presented in the committee stage against the London County Council (General Powers) Bill by the Greenwich District Board of Works, the London Electric Supply Corporation, and the Westminster Electric Supply Corporation.

Rhyl Pavilion.—A splendid new pavilion is being erected at Rhyl, to be completed by Aug. 15th. At the meeting of the directors, on Saturday, the question of electric lighting the new pavilion and the whole of the pier was discussed, and tenders are invited for carrying out the same.

Eastbourne.—The town clerk of Eastbourne has submitted the recommendation passed at the last meeting of the Eastbourne Town Council as to the lighting of the borough by oil or electricity, that the borough surveyor make enquiries from other boroughs upon the matter, and report fully thereon.

Water Power in Australia.—The proposal to utilise the River Yarra, at Warrandyte, near Melbourne, for generating electricity, has, it is said, taken definite form. A water license has been granted to Alcock and Co. for 15 years, and a company, according to the *Australasian Manufacturer*, is to be floated in London.

Burton Electric Heater.—The electric car heater invented by Dr. Burton is found by Lieutenant Dana Greene, who is their consulting electrician, to take a normal current of three amperes from the line, and the cost is given at 2d. a day per car. The John Scott legacy medal has been awarded to the inventor.

The World's Fair.—The finances of the Columbian World's Fair, at Chicago, are in a favourable condition, ten million dollars having been subscribed. The work of preparing the grounds of 600 acres extent is virtually completed, except the dredging of the lagoon. The contracts for many of the main buildings have been awarded.

The City of London Company.—Next week will probably see the formation of the new large company for the lighting of London, to take over the plant and contracts of the City of London (Pioneer) Electric Lighting Company. The latter shares will be taken over at a very considerable premium, and a good field of success is open for the large company.

Rochdale.—At the meeting of the Gas Committee of the Rochester Town Council on July 1, the town clerk laid before the meeting a notice of the intention of the Rochdale Electricity Supply Company, Limited, to apply to the Board of Trade for a provisional order (to be confirmed by Parliament in the ensuing session) to supply electricity in the borough.

Taunton Exhibition.—It was suggested at the Electrical Trades Section of the Chamber of Commerce that the Taunton Exhibition would better suit the convenience of exhibitors if held later. Mr. Massingham did not think it possible to alter the date, and as opinions were equally divided, it was finally resolved to give cordial support to the exhibition.

Demagnetisation of Watches.—Mr. J. S. Matheson, of Leith, owing to the number of watches spoilt at the Edinburgh Exhibition, has recently patented a process for thoroughly demagnetising watches so affected. We were of opinion that the system of gradually diminishing alternating magnetisations for this purpose was sufficiently practical and open to all.

Telephone in Honolulu.—The telephone is more used in Honolulu than any other place, the two rival companies cutting rates until every soda-water stand has its telephone, and all the marketing is done by this means. Even trams and railway trains are started by telephone, and men use their legs as little as possible in this hot clime with such facilities for verbal intercourse.

Steam v. Electricity.—A very suggestive occurrence has just taken place in the abandonment of the steam railway traffic on the 10-mile line between St. Paul's and Mineapolis in consequence of the competition of the electric railway. The *Railway Review* regards the problem as serious, and warns railway engineers that they must now be prepared to face fierce competition on the shorter lines.

Public Lighting in South London.—The Deptford Company have not yet received any orders for public lighting, except the small area of St. George's-circus. The corporation are, however, sanguine of eventually securing the public light over a considerable part of the district, which includes Westminster Bridge-road, Newington Causeway and Butts, Southwark-street, and Borough High-street.

Loughborough.—At the monthly meeting of the Loughborough Town Council, on Monday, the Mayor, on the passing of the General Purposes Committee's minutes, said, with reference to the electric light, they would remember that a committee was appointed in anticipation of some company seeking to obtain powers. It might interest the Council to know that no application had been made by any company.

Clerkenwell.—The Clerkenwell Vestry had before them, at their meeting on Wednesday, a letter from the Brush Electric Engineering Company, giving statutory notice of their intention to apply to the Board of Trade for a provisional order to supply electricity within the area of Clerkenwell. Also similar letters from the County of London Electric Lighting Company, and the Camberwell and Islington Electric Light and Power Company.

Audenshaw (Lancs.).—At the monthly meeting of the Audenshaw Local Board, Mr. Cooper said he had received a letter from an electric light company, but it was so badly written that he could scarcely read it. It was not thought necessary to read the letter. The Council felt they would have to follow the lead of greater authorities, and they could not do anything. The letter was then handed to the members for perusal.

Faraday and Sandemanian.—Referring to an extract which appeared some days ago respecting Faraday's religious and scientific opinions, the elders of the church known as Sandemanian, meeting at Barnsbury-grove, have written to the *Daily Telegraph* to state "that Faraday's scientific work never came into conflict with his faith in the Scriptures, and was never the cause of any trouble or misgiving to his church friends."

Stroud.—The Stroud Board of Health are exercised over the question of public lighting. The Lighting Committee drew attention to the improvements in the electric light, and suggested that, if the Board desired, enquiries might be made as to the cost of electricity. It was suggested that application should be made to Mr. George Norman, of Cheltenham, for information, that gentleman having made strict investigations all over England.

Electric Executions.—Four criminals were executed by electricity on Tuesday in New York. The official spectators were sworn to secrecy. Dr. Rockwell states that everything passed off quietly and expeditiously, death being instantaneous. Dr. Daniels, on the other hand, states that the Kemmler scene was repeated. By one report two shocks each were given; another states that only one shock each was given, and no burning took place.

Incandescent Lamp Manufacture.—It is announced that Captain François Walter, captain of artillery, and professor in the technical military school at Vienna, has made an invention which will revolutionise the incandescent lamp trade, being a method of welding other metals to glass instead of platinum. This kind of vague announcement, however, is worthy of little credence at present; technical details to warrant any attention being given to it are not to hand.

Kinetograph.—Another rival to Edison's invention of the kinetograph is found in an English invention, the "kinesigraph" of Mr. W. Donisthorpe, a barrister, and Mr. W. C. Crofts, Westminster-chambers, 7, Victoria-street, Westminster. Like Edison, these gentlemen take a series of consecutive photographs on a continuous film of sensitive surface, and combine them on a screen by the aid of an optical lantern. The date of their patent is August 15, 1889, or nearly two years ago.

Liege.—For parents thinking of sending their children abroad Liège offers many advantages. It has a fine university, with over 70 professors and 1,500 students, with new physiological, engineering, and chemical laboratories. The French spoken is the best in Belgium, and as students attend from all countries, by judicious choice of friends other languages may be learnt. Only five or six British students yet attend, but it is probable when its advantages are better known more will go.

The Phonopore.—We believe these instruments are being made in some quantities for practical work and tests. Some 250 of these instruments, in Morse form, working with what may be termed the ghost or skeleton of a current, which does not affect the ordinary instruments, are being made, and we understand that a severe test is being arranged by the chief electrician of one of the large railway companies. If this highly ingenious but hitherto delusive instrument can only be made absolutely practical, the possibility of doubling or trebling the ordinary instruments on a single railway line would certainly open a large field of additional usefulness.

Telephones and Tramways.—With reference to the recent disputes as to the vested interests of telephone companies in the "earth" circuit, it is interesting to note that in the United States, before the Ohio Supreme Court, it has just been decided that, as the roads in a municipality are for the purpose of facilitating public travel, the previous use by the telephone company of this road, or part of it, as a circuit does not prevent the electric tramway using it for its proper purpose, and that the telephone, as against the tramway company, will not have a vested interest and exclusive right to the use of the ground circuit as part of the telephone system.

Lighting of London.—At the meeting of the Commissioners of Sewers on Tuesday, the clerk said he had received a notice from the Brush Electrical Engineering Company of their intention to apply in the next session of Parliament for a provisional order authorising them to supply electrical energy for any public or private purposes within the City of London. Also a notice from the Laing, Wharton, and Down Construction Syndicate of their intention to apply in the next session of Parliament for a provisional order authorising the said syndicate to amend the City of London (East District) Electric Lighting Order, 1890. These communications were referred to the Streets Committee for consid

Ferranti System.—Mr. Ferranti stated at the meeting of the Municipal Engineers the other day, that high-pressure electrical engineers could now guarantee that 85 per cent. of the total electricity generated in the station could be delivered and sold to customers, and that if they could guarantee this, it was evident that in practice they could surpass this amount. We understand that the Deptford station is now supplying about 30,000 lights. The districts around Blackfriars are being wired, and several installations are being supplied at Deptford and Bermondsey. At Havre, where the Ferranti system is in force, a complete new low tension network has been laid down and a new 500 h.p. dynamo added.

Primary Battery Cars.—Experiments are being made by Mr. George B. Pennock, in Peoria, with a primary battery car. Mr. Pennock was assistant to Prof. Page, in 1851, when he ran an electric car at 20 miles an hour between Washington and Blandesberg, and is still a great believer in zinc. The Pennock battery consumes ½lb. of zinc per horse-power per day, and even at double this he gives the cost at 1½d. per horse-power a day. It is stated that in a few days the first electric locomotive in the world to be driven by primary batteries on the regular steam railways will be at work. A company is formed with half a million dollars capital, and Mr. Pennock announces that he proposes to run a passenger train between Chicago and New York during the World's Fair.

New Chemical.—Prof. Traube, of Breslau, has noticed the formation of a crystalline deposit on the anode when electrolysing an acid containing at least 40 per cent. of sulphuric acid. Prof. Traube assigns to this product the formula SO_4, which might be written SO_2O_2 by analogy with oxygenated water, H_2O_2, whose properties are of the same order. In fact, the compound SO_4 put into contact with oxide of lead forms sulphate of lead with disengagement of oxygen. M. Berthelot isolated a compound, S_2O_7, by electrolysis of sulphuric acid, and named it persulphuric acid. There is reason to believe, says the *Bulletin de l'Electricité*, that this persulphuric acid is a combination of sulphuric anhydride and the compound SO_4. We may thus write—$S_2O_7 = SO_3\ SO_4$.

Electric Bells.—Tenders are invited by the London County Council for making perfect and maintaining in thorough repair the whole of the electric bells and wires, and the apparatus connected therewith, fixed in the land and river stations of the Fire Brigade, and in houses used as lodgings for firemen. Specification, form of tender, and particulars may be obtained on application at the County Hall, Spring-gardens. Each tender must be accompanied by a declaration that the person tendering pays the rates of wages and observes the hours of labour usually accepted as fair in the trade. Tenders, addressed to Mr. H. De la Hooke, clerk of the Council, Spring-gardens, S.W., endorsed "Tender for Maintenance of Electric Bells," are to be sent in by noon on the 14th inst. Persons tendering must have offices and workshops in the county of London.

Burton.—The Gas and Electric Lighting Committee of the Burton Town Council presented a report last week in which they asked permission to exercise and carry out the provisions of the Burton-upon-Trent Electric Lighting Order, 1890, to obtain a site for electric lighting works, and to advertise, subject to specifications and conditions, for tenders and proposals of electric lighting systems, the execution of works, and the supply of machinery at a fixed sum. It was also stated that it would be necessary to obtain a piece of land, 4,054 square yards in extent, adjoining the gas works, and as Mr. Fenning had consented to lease the ground at £16. 17s. 10d. ground rent on condition that trade erections were constructed thereon to the value of £500, the committee recommended that the land should be secured. It was determined to advertise for tenders.

"The Journal of Gas Lighting."—It would hardly be courteous to say this paper deliberately propagates falsehoods, but until it can advance proof of the following statement we shall hold that its dictum is absolutely unworthy of belief. Referring to Mr. W. H. Preece's address to the Municipal Engineers, it says: "which we (the *Journal of Gas Lighting*) alone, of all the technical journals, specially reported last week." The *Journal of Gas Lighting* has a "bee in its bonnet" so far as electricity is concerned, and according to our judgment is not unwilling to mislead its readers upon such matters. The above statement as regards reporting is absolutely false. The *Electrical Engineer* and the *Contract Journal*, two technical papers, were represented throughout the meeting, and at all the visits to works. Not only so, but the *Electrical Engineer's* report was revised by the author.

The Thunderstorm.—London was visited with a very fierce and prolonged thunderstorm on Wednesday afternoon, during which the flashes of lightning and peals of thunder were almost incessant. The rain fell in torrential manner almost unsurpassed in the tropics, and ·6 of an inch was registered within an hour or so. Considerable damage was done, several houses were set fire to, and a man standing under a tree at Tottenham was struck and his clothes literally torn to ribbons, though the man was fortunately not killed. For the first time in its history the Royal Botanic Society had a tree struck by lightning. In the gardens, Regent's Park, a poplar was, at 4.30, during the thunderstorm, stripped cleanly in places of huge pieces of its bark and timber. Some workmen, who were busy preparing for the society's *fête*, were close to the tree, but sheltered beneath the wet canvas of the adjacent tents they suffered no hurt.

Kingswood.—At the meeting of the Kingswood Local Board last week, the clerk read the correspondence that had passed between himself and Messrs. Christy and Son, Chelmsford, who had tendered for the lighting of the district by the electric light. After opening the tenders, he had, in accordance with instructions received, written to Messrs. Christy asking where the members of the Board could inspect an installation laid for public lighting purposes, and also certain questions as to the decrease in the candle-power through wear. A reply had been received giving the required information, and stating that the nearest public installation laid by the firm was at Chelmsford, near London. An inspection of this service would be especially useful to the Board, because it was almost exactly similar to the requirements of Kingswood. Private installations had been laid at Messrs. Grace Bros. and Messrs. H. H. Budgett, Bristol, which could be inspected if desired. An inspecting deputation was appointed.

High-Tension Transmission in Vienna.—M. Zipernowski has invented, it is stated, a combined system of utilising continuous and alternating currents, with the idea of working in Vienna an electric tramway travelling at 25 miles an hour. A generating alternate-current dynamo placed at some distance away, giving a current of 10,000 volts, will drive a motor in a secondary station. This motor, which has to be put into step with the generator, will drive a continuous-current dynamo, whose current will be used to feed the car motor. This system will enable those natural forces to be used which are otherwise too far away to be utilised by means of continuous currents alone. The carrying out of this scheme, if intended to be a practical project, will be watched with equal interest to the transmission of power

to Frankfort. By the use of a subsidiary steam or other engine to put the second alternate dynamo in step, the necessity of a third wire will, we suppose, be obviated.

The Supply of Power from Central Stations.—About 20 years ago a bequest of £500 was made to the Society of Arts by Mr. T. Howard for the purpose of presenting a prize to the author of a treatise on motive power. The prize having on several occasions been offered without any practical result of value, the council considered that the most useful way of dealing with it would be to invite some eminent authority to deliver a course of lectures on a subject coming within the terms of the trust, on the understanding that the lectures should afterwards be published as a treatise. The result was that Mr. Anderson delivered, in 1884-5, the valuable course which were afterwards republished under the title of "The Conversion of Heat into Useful Work." Since that time the interest of the fund has accumulated to a sufficient extent to allow the council to repeat their action, and they have accordingly invited Prof. Unwin to deliver, during the next session, a course of lectures on "The Generation of Power at Central Stations, and its Distribution therefrom."

London County Council.—Sanction is given by the London County Council to mainlaying by the Kensington and Knightsbridge Company at Rutland-gate; to the Electricity Supply Corporation across the Strand to the Adelphi, to Northumberland-street, Whitehall, Charing Cross, Trafalgar-square, Pall-mall, St. Martin's-lane, Haymarket, and Leicester-square; to the Westminster Company in Buckingham-street, Queen Anne's-gate, Downing-street, Richmond-terrace, Parliament-street, Great George-street, Broad Sanctuary, Victoria-street, etc.; to the London Electric Supply Corporation for trunk mains from Cockspur-street through St. James's Park to Buckingham-gate; to the Metropolitan Company, in Leicester-place and across Cranbourne-street. The Parliamentary Committee report that in the opinion of the Highway Committee, in which they concur, the substitution of the Vestry of Chelsea for the Council as electric lighting authority in that parish would be unsatisfactory, and that they have directed a petition to be prepared and, if necessary, presented against the Bill.

Conversazione.—The president of the Institution of Electrical Engineers (Mr. William Crookes, F.R.S.) and Mrs. Crookes received a brilliant company of over 800 guests at a *conversazione* in the galleries of the Royal Institute of Painters in Water Colours, on Monday. The visitors greatly enjoyed the very fine exhibition of portraits, the band of the Coldstream Guards, the strawberries, and coffee-ices, and interchange of social amenities. Besides the members of the Institute—Sir Wm. Thomson, Mr. W. H. Preece, F.R.S., Mr J. W. Swan, Dr. S. P. Thompson, Prof. Ayrton, F.R.S., Prof. Perry, F.R.S., Dr. Hopkinson, and others—were many noted guests, among them being Sir F. Abel, K.C.B., Sir James Douglas, Dr. Gladstone, F.R.S., Earl Russell, Duke of Marlborough, Sir Edwin Arnold, Sir F. Bramwell, F.R.S., H. Perigal, F.R.A.S., General J. T. Walker, F.R.S., Sir Benj. Baker, K.C.M.G., Sir G. B. Bruce, Hon. H. A. Dillon, Sir Philip Magnus, Sir E. J. Reed, Sir H. Doulton, Mr. W. J. Karner and Mr. E. L. Corthell (Chicago Exhibition), Mr. Wimshurst, Mr. Ferranti, Dr. Ernest Hart, Mr. Ganz, and many others.

Electrical Manufacture of White Lead. In an article in the *Revue Industrielle* for July 4, the electrolytic process of forming pure white lead is discussed from its theoretical and practical points of view. The description is given of a commercial process recently patented, the adaptation of a well-known laboratory experiment. In a suitable vessel is prepared a solution of nitrate of ammonia and nitrate of soda, five parts by weight of each to 100 parts of water. Two pigs or plates of lead are placed therein, and the bath is saturated with carbonic acid in a nascent state. This is economically obtained by burning lime. When the bath is rendered almost neutral, the two pieces of lead are put into connection with the poles of a dynamo giving [illegible] amperes per 100 square centimetres of surface of lead in contact with the positive electrode. As soon as current passes, white lead appears at the surfaces of the two pieces of lead, and by continuing to saturate the bath with carbonic acid, and prolonging the passage of the current, the whole can be transformed into white lead, which is then taken out of the bath, washed in a 6 per cent. solution of salt water, and dried, producing a commercial product with exceptional covering qualities, composed of one part of hydrated oxide of lead to two of carbonate of lead. The only expense of manufacture after the bath is set up is in the production of the carbonic acid and the current, and this is stated to be considerably less than that of the present forms of apparatus in outlay, wages, and time.

Registering Instruments.—Science progresses by the study of fact, by the evolution of theory, the adaptation of theory and fact to use, and the consequent study of results. In science, to have results is not enough: we must have records of these results, records from day to day, from year to year. Therefore, the success which attends all really good attempts to satisfy the demand for registering instruments. No firm has done more in this way than the well-known one of Richard Frères, 8, Impasse Ferrard, Paris, whose London branch is 43, London-wall (manager, Mr. J. A. Berly). We have before us their catalogue of measuring, controlling, and self-registering instruments for scientific and industrial purposes. "We manufacture," they say, "every kind of registering instrument that may be required in science and industry. Should any of our customers fail to find in this catalogue the instruments they desire, we will, on their indication of the results they have in view, and the phenomena they intend to control, study the type of registering instrument suitable for their purposes," and endeavour to bring out such an instrument. They produce three kinds of measuring apparatus—engineering, electrical, philosophical. Their list of medals and awards is very numerous, embracing those from 1845 to 1890. We find in the catalogue registering anemometers, barometers, chronographs, dynamometers, hygrometers, speed recorders, water-level indicators, pressure gauges, pyrometers, thermometers, volt and ammeters, charge and discharge recorders, and recording electricity meters, besides numerous others in special departments of meteorology. We advise all electrical engineers to possess themselves of this valuable catalogue.

Chelsea.—The Select Committee of the House of Lords last week, presided over by Lord Basing, considered the Electric Lighting Bill to confirm a provisional order granted by the Board of Trade to the New Cadogan and Belgrave Electric Supply Company, Limited, to enable the company to supply the electric light to a part of the parish of St. Luke, Chelsea. The Bill was opposed by the Vestry of Chelsea on the ground that it made the London County Council the local authority under the order. Mr. T. Holland, clerk to the Vestry, said the Electric Lighting Act of 1882 and 1888 specified the Vestry as the local authority for all purposes under the Acts, and Parliament never intended to give control or powers over electric lighting to any other body than the local authority as

fined by these Acts. By making the London County Council the local authority a concurrent jurisdiction would be established, which might, and probably would, lead to a conflict between the Vestry and the County Council, and when the Vestry became the undertakers the County Council would exercise an authority over their supply, which should be left to the inhabitants of the district. The chairman said he saw no reason why the Vestry should not be the local authority. Mr. Cripps, parliamentary agent, representing the London County Council, said the Vestry raised no objection to the Council being the local authority under the order of the London Electric Supply Corporation of 1889. Mr. Holland replied that that order extended to nearly the whole of the metropolis, and the parish of Chelsea only formed an integral portion of that area. Therefore, the undertaking could not in any sense be regarded as a local one. The chairman said the committee were unanimously of opinion that the Vestry ought to be the local authority under the order. The Bill was amended accordingly, and ordered to be reported to their Lordships' House. These propositions were made to the House of Commons Committee by Mr. Moon, chairman of the Electric Lighting Committee, and Mr. Whitmore, M.P., but rejected. As seen above, Mr. Holland succeeded in carrying them through the House of Lords Committee.

Gas v. Electricity at Leeds.—Mr. Walter Rowley, M.I.E.E., Meanwood, Leeds, writing to the *Leeds Mercury*, has some very *apropos* remarks upon Mr. Preece's paper last week before the Incorporated Association of Municipal and County Engineers. "Such a statement of facts from the chief electrician to the General Post Office," says Mr. Rowley, "is one that cannot fail to direct the attention of all municipal bodies to the subject, and not allowing such considerations as existing gas works to retard or diminish the adoption of a form of lighting which, on account of its cleanly and sanitary nature, is far preferable to gas. The figures given by Mr. Preece are a remarkable confirmation of the statements made by Alderman Spark when the discussion in the Leeds County Council took place, and we are indebted to him for the very manly way in which he fought for the electric light. Although defeated in their efforts to secure for the town an efficient and cheap electric lighting system, the minority which Alderman Spark represented will before long be shown to have taken the right position. The effect of handing over the lighting of the town to private companies will be that they will only take their systems into the thickly-populated districts, unless compelled to do otherwise; ratepayers in districts farther from the centre of the town, having equal rights to the supply, being left unprovided for. The lighting of a town is one of the duties which ought to be fulfilled with the greatest economy by the local authorities rather than by private ventures. After such a statement as that of Mr. Preece, it must be admitted that electric lighting has now fairly passed out of the experimental into the really practical stage; and, on behalf of those who know the advantages of electric lighting for domestic purposes, this appeal to the authorities is made, and I would ask all to rise above party feeling in this matter, and combine in an effort to secure with as little delay as possible the supply of the electric light to all ratepayers who desire it. The question is one that claims the serious and unbiassed consideration of those upon whom rests the responsibility of supplying (or refusing) a want which all who are intimately acquainted with the subject believe to be a requirement in the public interest. The importance of this matter has induced me to address this letter, in the hope that, even at the eleventh hour, the attention directed to the subject may have the result of making the supply, under existing circumstances, as extensive and complete as possible."

Trial of the Gordon Electric Car.—At Messrs. Merryweather's works, Greenwich, on Tuesday, we had the pleasure of witnessing a trial run of the Gordon closed-conduit electric railway. As it is not improbable that a long section of tramway may be shortly fitted up with this system, it may be worth while drawing the attention of tramway and electrical engineers somewhat forcibly to this system, a paper about which was read by Mr. Gordon himself at the Tramways Institute meeting last week, reproduced elsewhere. A line of tram rails exists at the back of Messrs. Merryweather's works, and this line has been fitted up by Mr. Gordon as an experimental line. A car trolley completely fitted with motor gears and switching apparatus is in actual working order, and seems to behave admirably. The principle adopted by Mr. Gordon is ingenious, and the working out of it not less so. The conduit carrying the current for the motor is a very small one, some 2in. or 3in. of ground being quite sufficient to contain it. The supply rail is laid midway between the two line rails, and consists simply of flat iron laid in concrete in lengths of about 8ft., or one-third the length of the car. The system arranges for charging these sections by the full current of, say, 400 volts, as the car progresses, so that no section is charged except those under the car. This is done by a system of connections laid in a gas-pipe with tee-pieces connecting to each length and leading back to a commutating box, which is the feature of the system. These boxes are placed every 100 yards under the kerb, and contain strong long-pull magnets, one for each section. As the car progresses, a shunt current comes back from the section No. 1 to the magnet No. 2, which rises and puts section No. 2 into connection, cutting off No. 1, and so on, as the car moves—the main, of course, running the entire length of the road. These boxes are of very strong construction, and, as seen on the trial, act with precision and force, being able to withstand rough usage. The current being turned on, the car moved forward at considerable speed, and it is interesting to watch magnet after magnet rise and fall, like the keys of a piano, one after the other with absolute precision and not the least sparking. The pull of the magnet is about 7lb., and evidently is more than ample to do its work. The car was run backwards and forwards by Mr. Gordon, under complete control, nothing more being required than the movement of the car switch, which acts both as resistance and as reverser. The advantages of the system are the use of the closed conduit—no slot or wires that can be touched being needed; the small cost of conduit, and corresponding small cost of alteration of track. Not the least effective advantage of the Gordon system is that, by the addition of one contact, the absolute metallic return for the current can be made by way of the section behind, and thus the difficulty with the telephone companies can be avoided—a matter impossible of arrangement with most systems without costly additions to the mains. The cost of alteration of track and laying the electric conduit is estimated (the figures being checked by Messrs. Merryweather's engineer) as £2,000 per mile, of which £25 each is the cost of commutator boxes. The cost of a new electric car would be £400. Mr. Gordon, allowing all possible contingencies, estimates the actual cost of traction 2½d. per car mile. As to the commutator boxes, our opinion is that these will do their work, and are not in the least more fragile than the commutator bars themselves of the dynamo.

TELEPHONE TRANSMITTER PATENTS.

BY A. R. BENNETT.

No doubt the directors of the National Telephone Company believe that there are good grounds for the warning recently conveyed to the public by their advertisement *re* the Hunnings, Blake, and Crossley transmitters—that those patents are really valid, and that they are performing an act of kindness in cautioning all and sundry against them.

But it does not follow that their advertisement should be accepted without discussion. It would be sorely against the public interest to suffer telephone enterprise to be crippled, and development arrested for another 18 months, simply out of deference to the not altogether disinterested opinions of the National Company's directors. Their duty to the shareholders would require them to put the best complexion on the matter, even though they had their doubts, and it behoves those interested from the opposite point of view to examine their statements and judge for themselves whether they can be substantiated or not.

I have recently had occasion to enquire somewhat narrowly into the actual status of the very three patents mentioned in the advertisement, and I have much pleasure in acceding to the suggestion that I should make public my conclusions and the reasons for them.

In the first place, I consider that the National Company is apparently inclined to attach far too little importance to the labours of our distinguished countryman, Prof. Hughes. A good many months before the date of the first secondary patent Prof. Hughes showed how more efficient telephonic transmitters than any devised by Edison could be constructed out of conducting powders and fragments of

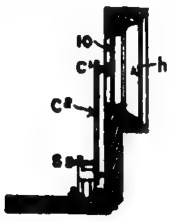

FIG. 1.—10, diaphragm; *h*, mouthpiece; c^2, spring c^1, contacts; *s*, regulating screw.

charcoal; but inasmuch as Edison was before him with his tension regulator patent (No. 2,909, of 1877), and that patent mentioned variable contacts and carbon in the form of lampblack, it was held that Hughes's discoveries were anticipated and covered by Edison. As a result, the expiry of Edison's patent on July 30th next will not only set free all the forms of transmitters described in it, but also all the forms invented by Prof. Hughes, and will further allow of some of Edison's transmitters being improved into really efficient instruments by the substitution of hard carbon for the plumbago points and semi-conducting tufts originally imagined.

Edison's specification is a voluminous one, and amongst a mountain of dross contains, comparatively, but few grains of gold. Before proceeding to the examination of the three chief secondary patents, it would be well, therefore, to briefly indicate the chief points he makes, and ascertain what features of value become free in August through the lapse of the Edison rights.

The passages in his specification bearing most on the practical question are as follow:

EDISON (No. 2,909, JULY 30TH, 1877).

A. Page 5, lines 6 to 16.—Description of diaphragm preferably but not necessarily of mica, secured at its edges. Amongst others Edison mentions diaphragms of metal.

B. Page 6, line 5.—"In some cases I make use of a variable resistance resulting from greater or less intimacy of surface contact.

C. Page 6, line 31.—"In some instances I make use of the best quality of lampblack."

D. Page 7, line 15, Fig. 10.—"*h* is a resonant chamber at the end of which is the diaphragm 10, and at each side of this diaphragm there are springs, *C2*, *C3*, having points made up of compressed plumbago. . . . These points face each other on opposite sides of the diaphra[
make contact with platina disks secured to the diap[

E. Eighth claim is for an adjusting screw or presser to regulate the resistance of the tension reg[the electric circuit.

F. Fig. 24 is a diagram of a microphone and ba[the primary circuit of an induction coil, of whi[secondary is to line and earth.

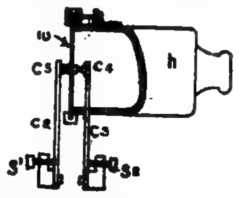
It may be remarked, however, that Edison had r[to claim this combination, since Dr. Wright as far [1867 used an induction coil in connection with [transmitter, and Cromwell Varley afterwards emp[with his musical telephone.

Edison's Fig. 10, which is reproduced, shows a[phone carrying two platinum discs, against wh[pressed plumbago points mounted on springs, the [between the platinum and the plumbago being r[by adjusting screws applied at the base of the sprir[

The expiry of Edison's patent of July 30 t[frees:

1. Diaphragms fixed at their edges.
2. Variable resistances resulting from greater [intimacy of surface contact. This is practically th[phone.
3. Lampblack (soft carbon).
4. Springs for carrying microphonic contacts.
5. Screws for regulating the pressure exerted [springs.
6. Combination of microphone, battery, and i[coil.

So after July 30 any person will be free to us[all of these factors, provided he combines them in a[not effectually protected by subsequent inventors.



EDISON'S FIG. 10.—10, diaphragm; *h*, mouthpiece; c^2, c^3, c^4, c^5, contacts; s^1, s^2, regulating screws.

The discoveries of Hughes already alluded to [the foregoing free list by the addition of *hard* [multiple surfaces, and conducting matter in the [powder. It will be permissible to combine or inte[Edison and Hughes's discoveries. With such ma[command, the telephone engineer who cannot de[efficient transmitter and still keep clear of Hunni[Blake, may reasonably be adjudged to have mista[vocation.

I shall now submit the secondary patents t[analysis with the view of ascertaining how far t[original, and whether they do not run some risk o[indicted as (to borrow a term from the National Co[advertisement) "colourable imitations."

HUNNINGS (No. 3,647, SEPT. 16TH, 1878).

Hunnings's claim is essentially for the use [powdered carbon confined in a loose state betwe[metallic diaphragms, one of which is vibrated by th[

Hunnings preferred thin platinum foil for his vi[diaphragm, and seemed to consider a metallic or a[covered diaphragm indispensable. That is what h[shadows in his provisional and claims in his fin[there is no suggestion as to the practicability of [diaphragms into the composition of which metal d[enter, except in one place in the final, where [enumerating platinum, iron, and silver, he adds "o[material." But it is evident that if "material" [actually a misprint for metal, the other material he [view must have been metallic in its nature, since no a[is made to the special contact or electrode that w[necessary were wood or other non-conducting m[employed.

Hunnings's own words may be quoted as showin[he believed to be new in his invention. After disc[

...ight to Hughes's microphone and Edison's carbon ...one, he says: "But what *I believe to be new and desire ...im as my invention* under the hereinbefore-in-part ...d letters patent is: 1. The use of finely-powdered ...on, *or like conductor* (preferably oven-made engine coke ...pared as described) in a loose and free state (not com...essed or consolidated in any way or combined with foreign ...terial) as a means of varying the resistance of a tele...onic circuit by the vibrations of a thin *metallic or metal...ered diaphragm* enclosing it, controlled by the sound-waves

Front.

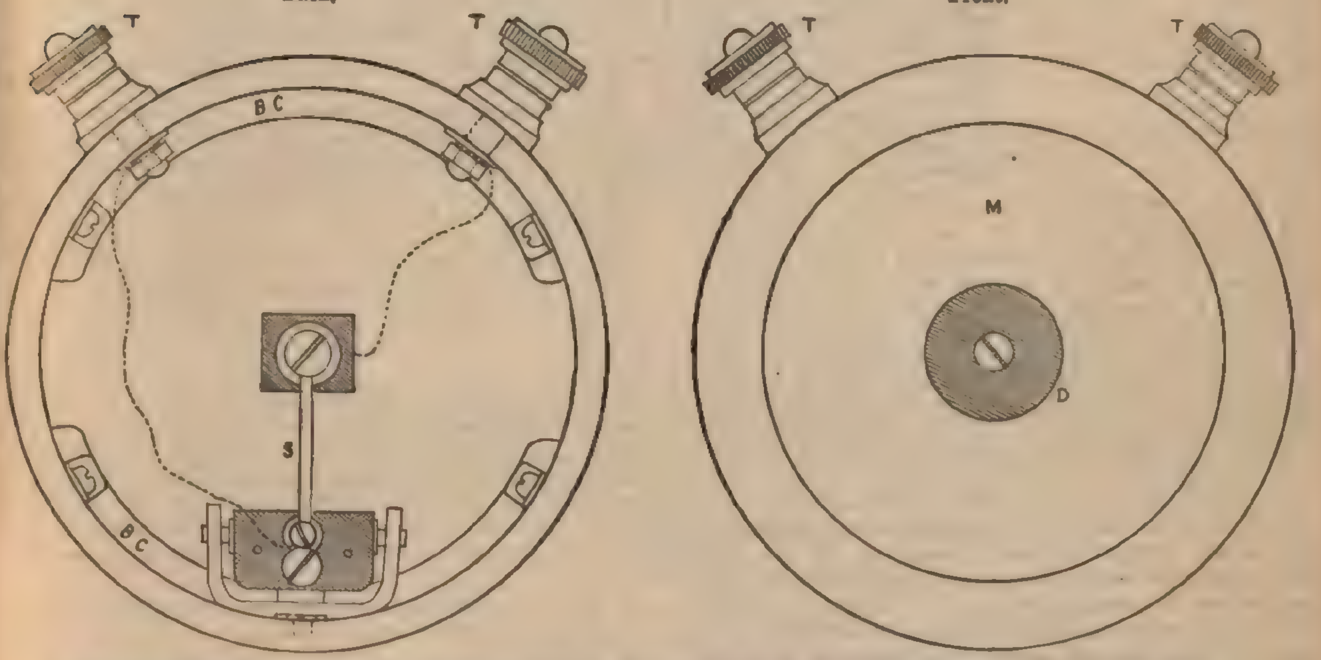

FIG. 2.—Details of an Efficient Transmitter outside the Secondary Patents that may legally be used after July 30th.

B C, brass clamp; C C, carbon contact; C B, carbon block; D, diaphragm; I R, indiarubber ring; M, mouthpiece; R S, regulating screw; S, spring; T, terminal screw.

impinging upon it. 2. A telephone transmitter consisting of a layer of finely-divided carbon or similar conducting material, preferably oven-made engine coke, placed in a loose and free state between the thin *metallic or metal covered diaphragms* in a suitable case, and for the purposes described."

Since these claims avowedly cover all that Hunnings believed to be new, and expressly exclude all but metallic or metal-covered diaphragms, it surely would not be complimentary to Hunnings to rule that he meant wooden and carbon diaphragms as well, although he was not aware of it.

The point is of importance, because about nine months later Marr (No. 2,497, June 21, 1879) protected a transmitter of powdered carbon confined between two wooden diaphragms, having carbon discs attached to their centres as contacts. This combination, although invented by Marr, was generally known as the Moseley transmitter. The patent is now void, and if held free of Hunnings, would be open to all after July 30.

Subsequently, Moseley (No. 1,320, January 30, 1885) and Berthon (No. 2,893, March 4, 1885) employed powdered carbon confined between diaphragms of thin carbon plate. Of these, Moseley's has lapsed, but Berthon's is still in force, although its validity in face of Moseley's prior claim for granulated carbon between carbon diaphragms is considerably more than doubtful.

The diaphragm is not the only weak point about Hunnings's, for Hughes, in his paper before the Physical Society (*Nature*, June 27, 1878), stated that he had discovered that a current passing through conducting matter in a divided state, either in the form of *powder*, filings, or surfaces, was varied under the influence of the slight pressure applied by sonorous vibrations. This specific mention of conducting powder by Hughes four months before Hunnings applied for his patent, precludes the latter from claiming any exclusive right to powdered carbon.

Again, on June 3rd, 1878, three and a half months prior to the date of Hunnings's patent, Prof. Blyth, of Glasgow, described in a paper to the Royal Society of Edinburgh (*Nature*, June 13, 1878), a transmitter consisting of pretty coarse fragments of gas cinders packed in a shallow box of thin wood, having tin (tinned iron?) strips at the ends to serve as contacts. The results obtained he described as satisfactory, although there was no front vibrating diaphragm. I have recently had an experimental transmitter made to Blyth's description, and find it is really an efficient instrument. The box speaks equally well, and very well, whether the voice is directed against the sides, bottom, top, or ends. By substituting carbon electrodes for Blyth's tinned ones, and extending them across the box, so as to reduce the intervening space to be bridged by the carbon particles, and by using fragments of proper microphonic carbon in lieu of Blyth's cinders, a transmitter of which no one need be ashamed is formed. The carbon may be much coarser than the powder described by Hunnings, but in view of Hughes's prior publication there can be no risk in using even the finest powder in a wooden box, no part of which partakes more of the nature of a diaphragm than another.

As we have seen that Edison was before Hunnings with

metal diaphragms, and Hughes and Blyth were before him with conducting matter in the form of powder and fragments of carbon, the most Hunnings can claim is a combination of the two, and he is, in fact, modest enough to so limit himself.

BLAKE (No. 229, JANUARY 20TH, 1879).

This is the next secondary patent in order of date. Blake's claims are five in number.

Claim 1 is for his method of holding a diaphragm by means of springs.	This need incommode nobody, since a diaphragm fastened at its edges as described by Edison is practically as efficient.
Claim 2 is for a spring carrying one of the microphone contacts, the other contact being carried by a second spring or fixed direct to the diaphragm.	It is difficult, in face of Edison's Fig. 10, to imagine wherein this differs from Edison's plan, which, omitting the superfluous second spring, could be described in the same words.
Claim 3 is for Blake's peculiar form of adjusting lever.	Of course Blake is quite entitled to this. The form of adjusting screw shown by Edison in his Fig. 10 is not a very good one, but others could be devised without infringing Blake's.
Claim 4 is for the combination of two contacts, each carried by a spring.	Edison's plan of one contact on a spring and the other on the diaphragm is practically as good.
Claim 5 is for the addition of a yielding weight to one of the springs, for the purpose of resisting the movement of the diaphragm and of modifying by its inertia the variation of pressure.	This has a strong resemblance to the device described by Hughes to the Physical Society (*Nature*, June 27th, 1878): "The upper contact of a microphone should have its inertia supplemented by a balanced weight. This inertia I find necessary to keep the contact unbroken by powerful vibrations. No spring can supply the required inertia." But such a weight is not really necessary.

In fact, a transmitter made up to Edison's Fig. 10, but with only one spring and one pair of contacts, which could both be of hard carbon in lieu of Edison's plumbago and platinum, speaks at least as well as the Blake, and with such a transmitter, Fig. 2, Blake could not interfere.

It would be unkind to an old acquaintance like Blake to hint anything about "colourable imitations," but there is certainly a family likeness between half of Edison's Fig. 10 (see Fig. 1), and the essential features of the Blake, a similarity accentuated by the coincidence that both inventors use platinum for one of their surfaces.

CROSSLEY (No. 412, FEBRUARY 1ST, 1879).

The last of the secondary patents to which importance is popularly attached is that of Crossley. It is a legal dictum that the contents of the provisional and final specifications of a patent must agree in substance. If they do not, or if matter is introduced into the final that is not foreshadowed in the provisional, then the patent is invalid, or, at least, the matter not so foreshadowed cannot be claimed. With the best intentions in the world, I must confess my inability to detect any novelty in Crossley's provisional or any resemblance between his provisional and final. The provisional is very short, and foreshadows an invention (!) consisting of nothing more nor less than "an ordinary microphone" (Crossley's own words) mounted on a parchment or other suitable diaphragm in conjunction with a battery and induction coil. Reading the provisional by itself, one would imagine that Mr. Crossley had lodged it under the impression that the use of an induction coil with a microphone was novel and with the design of protecting that combination.

But in the final it is stated (page 3, lines 26 to 28 and 56) that the induction coil is not necessary, only desirable. So the coil, not being a necessary part of the invention, must be deleted from the provisional, and then what remains? Nothing more than "an ordinary microphone mounted on a parchment or other suitable diaphragm." But the process of elimination can be carried further, for in the final "an ordinary microphone" is defined as having one pencil and two surfaces touching each other, "to which," Mr. Crossley wisely adds, "I lay no claim." Take away this disowned ordinary microphone from the provisional, and what remains? Clearly, a parchment or other suitable diaphragm; an appliance not altogether unknown to Reiss in the early sixties. But in the final, the term "compound microphone" is introduced, and defined as a microphone having three, four, or more pencils, and six, eight, or more surfaces touching each other. The figures show compound microphones of Crossley's well-known form, but the claim is not for this form alone, but broadly for microphones having three, four, or more pencils, and six, eight, or more surfaces. Putting aside for the moment the want of agreement between the provisional and the final, I do not see how such a claim can be sustained; for Hughes, in his paper to the Physical Society, June 8, 1878 (*Nature*, June 27, 1878), nearly eight months prior to Crossley's patent, said: "A man's voice requires four surfaces of pine charcoal, six of willow, eight of boxwood, and ten of gas carbon." In another paper (*Nature*, May 16, 1878) Hughes said: "The effect was improved by building up the nails log-hut fashion, into a square configuration, using 10 or 12 nails. A piece of steel watch chain acted well." Mr. F. J. M. Page, in a letter to *Nature*, May 30, 1878, speaks of three pieces of gas carbon in circuit with the primary of an induction coil and a Daniell cell.

These instances (and I could adduce others) of prior publication respecting multiple contacts are sufficient to destroy any particular claim to such contacts on Crossley's part. Even when arranged in his own special and highly meritorious form, the want of novelty in his provisional, and the startling disagreement between the provisional and final, would render interference on his part hopeless. Beyond all this, it should be borne in mind that an efficient transmitter can be made with only two pencils and four surfaces, and to this, in any form, Crossley could not even pretend a claim.

Mr. Crossley may, however, truly retort that although his patent may not have been drafted by a committee of Queen's counsel and patent agents, it was nevertheless very much to the purpose, since the innocent United Telephone Company gave him £17,500 for it! Crossley can certainly claim the laugh, if nothing else.

To sum up, for the reasons set forth, I believe that the following transmitters may legally be used after July 30:

1. All forms described by Edison in his No. 2,909, substituting, if desired, hard carbon for plumbago, platinum, etc.

2. A transmitter, resembling Blake's in general form, but with diaphragm secured round its edges, with one contact fixed on the diaphragm and with some form of adjusting lever other than Blake's, being practically Edison's Fig. 10. The details of such a transmitter, which contains nothing that was not anticipated by Edison, except the hard carbon contacts, which were anticipated by Hughes, are shown in Fig. 2.

3. All forms described by Hughes in his various papers.
4. Crossley's and analogous forms.
5. Blyth's.
6. Berliner's (No. 1,786, of 1884). A good transmitter, having contacts kept in position by gravity alone. Patent has lapsed.

Of these, Nos. 1, 2, 3, 5, and 6 could not be challenged without the challengers laying themselves open to an action for vexatious interference. No. 4 is safe for those who are not to be frightened by bluff, since there was absolutely no novelty of any description in Crossley's provisional, and his final claims something else. The following three would probably have to be defended if used, for, in spite of Hunnings having claimed only metallic or metal-covered diaphragms for his combination, they might be held as mere variations for the purposes of evasion:

7. Mun's. 8. Moseley's. 9. Berthon's.

The specialities that cannot under any circumstances be used are:

Until September 17, 1892: Powdered carbon in combination with a metallic or metal-covered diaphragm. Until January 21, 1893: Blake's method of holding diaphragm by springs; Blake's special form of adjusting lever; and Blake's combination of two contacts mounted on separate springs, being respectively Blake's claims Nos. 1, 3, and 4.

LIGHTING OF THE S.S. "SCOT."

The following details of the s.s. "Scot's" electric installation will be interesting. There are 680 lamps of 16 c.p., and 10 electric fans. Two of these latter are Blackman

Fig. 1.

fans driven by Crocker-Wheeler motors, and are used for extracting the foul air from the engine-room skylight. Of the other eight, which are made by Messrs. King, Brown, and Co., Edinburgh, two are downcast and supply air to the engine-room, the remainder exhaust the foul air from

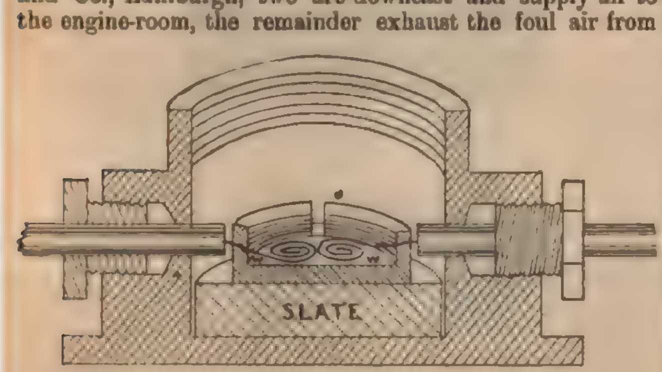

Fig. 2.

the cabins, etc. Current is supplied by three dynamos, by King, Brown, and Co., capable of giving about 200 amperes at 100 volts, driven direct by three compound engines, by Brown Bros., Edinburgh, at a speed of 200 revolutions per minute. Each dynamo has a tachometer attached, and the potential is measured by Sir Wm. Thomson's marine voltmeter. In the dynamo-room there is a main switchboard, Fig. 1, designed by Mr. Malcolm, Sutherland, and made in the electrical department of the Leven Shipyard, Dumbarton. It is 6ft. by 3ft., and is made of white marble steeped in paraffin. The lower part is occupied by three angle bars, which run from end to end, and to each of which a dynamo is connected through a fuse and ammeter clip. The upper portion is occupied by two rows of fuses and two-way switches, to which the fan leads and 14 main leads are attached. As has already been said, the switches are two-way, and to each of them two flexible electrodes are attached, one on each side, having clips on their ends by means of which they may be attached to any of the three bars. As each switch has two electrodes, one of which must always be idle, when it is necessary to change any circuit from one dynamo to another, the idle electrode is clipped on to the dynamo wanted and the switch reversed. In this way any circuit can be changed from one dynamo to another without interrupting the light. By means of the ammeter clips the current can be measured at any time by either of the two Siemens ammeters which have been mounted on the board. From this board the mains are led to 14 distributing-boards, also made in the shipyard works, placed in different parts of the ship. These boards contain switches and fuses, from each of which a wire is run to a group of lamps, the maximum number of which is eight. As the sectional area of the wire is kept uniform throughout, it is unnecessary to have any other fuses. Single wiring is used, except in the vicinity of the compass, where double wires are run; and to simplify the wiring, and make testing and repairs easier, soldered joints are superseded by a patent screwed junction made by W. McGeoch and Company, Glasgow, as shown in Fig. 2. This consists of a small brass pan about an inch in diameter over all, screw threaded inside, and with vertical slots cut in the sides. This is mounted on a slate base, and placed inside of a metal watertight junction-box, on the sides of which are small stuffing-boxes. To join two or more wires together, they are brought through the stuffing-boxes. The insulation is then removed, and the bare ends inserted through the slots and coiled up inside the junction pan. A soft tin washer is then laid on top of them, and a brass

button is screwed hard up on them. As the diameter of the screw is very large compared with its length there is no fear of it coming loose, and the surface of wire used in the joint being large, there is no heating. A very good joint is thus obtained without the trouble and danger of carrying heated bolts or blow-lamps about. It is also much easier to disconnect portions of any circuit when searching for a fault which may have occurred. One of these boxes is used for each lamp, the stalk of the lamp being screwed through the cover of the box and forming the return, the current being carried to the lamp by an insulated metal rod in the centre, at the upper end of which is a spring contact which presses against the button of the junction. All joints in the small wires are made inside of junction-boxes, and there are no joints in the main cables. All the wires are of high insulation, the mains being Silvertown vulcanised rubber, lead-covered, and taped. Most of the small lamps are wired with vulcanised rubber-covered wire, made by the International Okonite Company, and the remainder, comprising the engine-room, stokehole, deck lights, etc., are wired with Fowler-Waring lead-covered armoured wire.

TELEPHONE TRANSMITTERS.

A short time ago, having occasion to call upon Mr. Lewis, the genial manager of the Western Counties and South Wales Telephone Company, we noticed a diagram

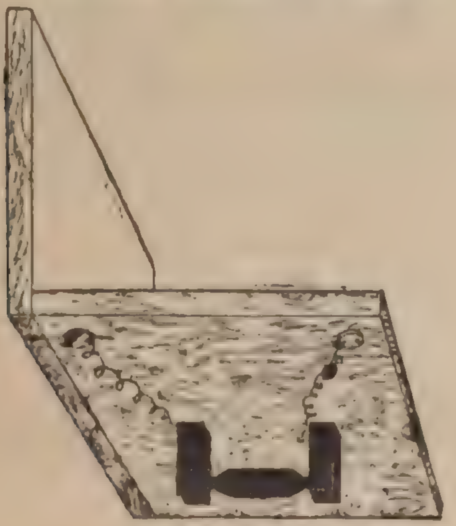

Fig. 1.

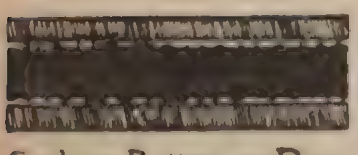

Fig. 2.

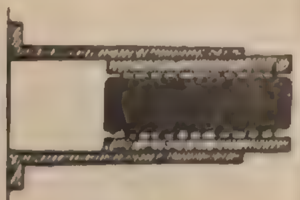

Fig. 2a.

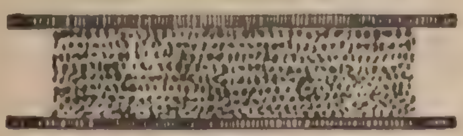

Fig. 3.

Fig. 4.

indicating the various forms in which carbon has been used in transmitters. Mr. Lewis very kindly acceded to our request, and by his courtesy we are enabled to give the accompanying illustrations. Fig. 1 shows one of the well-known forms introduced by Prof. Hughes. F and 2a show Edison's carbon button or disc, as in his transmitter, patented July, 1877, No. 2 Fig. 3, also Edison's, shows lampblack of the best qu

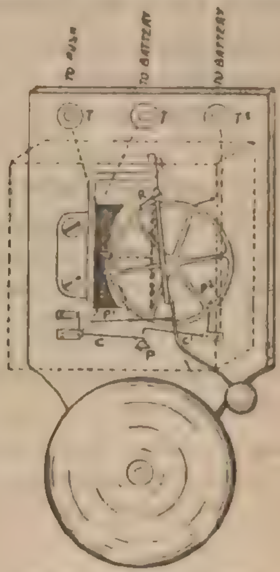
Figs. 8, 9, and 10 show other forms of transmitter, used under various names, and Fig. 11, the cup-and-ball microphone; Fig. 12, short pencil microphone; Figs. 13 and 14, other forms of cup-and-ball microphone; Fig. 15, Edison's carbon button slightly modified.

THE TOWNLEY PATENT AUTOMATIC MAKE AND BREAK CIRCUIT ELECTRIC BELL.

This bell is being introduced by Mr. B. Townley. From the claims made by the inventor, Mr. J. Townley, it bids fair to supersede the old form. Having little tension in the spring carrying the armature, it requires less battery power; having the magnetism retained in the armature until it does work, allows longer stroke and a more agreeable tone. It has sliding contacts, making it less liable for them to oxidise; it has an automatic make and break circuit; and the cost does not exceed that of the ordinary form.

Its description is as follows: The circuit is completed in the ordinary way by means of a push. The current passing through the terminal T on to the contact pin, P, along the bell crank, C, through the coves and out through terminal T^1 to the battery. The usual magnetic field is produced, the armature is attracted, carrying with it the adjusting pin, P^1, and the ratchet pawl, R, which actuates the wheel, while the adjusting pin, P^1, moves the bell crank, C, lifts one end from the contact pin, P, thus breaking the circuit, and allows the armature to attain its normal position, but during this movement a second bell

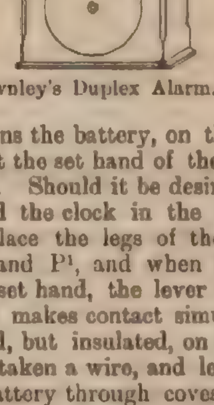


Townley's Electric Bell.

crank, C^1, is released and allowed to fall on the contact pin, P, by means of a pin, P^2, fixed on the wheel. The circuit is then allowed to take another direction out through terminal T^2, and on to the battery, this circuit being completed until the wheel makes one revolution, when again the pin on the wheel lifts the bell crank C^1, thus breaking automatically the circuit and allows the armature to come to a state of rest.

THE DUPLEX ALARM.

This alarm is being introduced in conjunction with the Townley patent electric bell. The two may be used together or separate. The clock being portable may be used independently, can be set to ring, and will continue for about two hours if not stopped. Switches and all other complicated parts are entirely obviated.



Townley's Duplex Alarm.

The box, B, contains the battery, on the front of which is fixed the bell. Set the set hand of the clock to the time the alarm is required. Should it be desired to use the two together, simply wind the clock in the ordinary way, but this is immaterial; place the legs of the clock, L and L^1, on the contacts, P and P^1, and when the hands of the clock agree with the set hand, the lever which releases the hammer of the clock makes contact simultaneously with a spring which is fixed, but insulated, on the frame of the clock, from which is taken a wire, and led to the insulated leg, L^1, on to the battery through coves and contacts of the bell, return to battery through leg, L, to where contact was made; the circuit being thus completed, rings the bell until the clock is moved off the contacts, P and P^1.

e Lineff system and the Jarman system are well own to our readers, but the Gordon system is less l known. We have therefore requested the author to e us an estimate of the cost and the returns of a : to be altered from horse traction to electric ction upon his system. Experimentally, the line has constructed at Messrs. Merryweather's is a ccess It has been tested under stringent condins, and acted well even when saturated with water covered with mud. The figures of the following imate must be considered with care, and it would well if rival systems would give similar estimates. any rate, we should then get a basis for calculan, and the various items could be compared:

TIMATE OF THE CAPITAL COST OF APPLYING THE GORDON SYSTEM OF ELECTRIC TRACTION TO AN EXISTING TRAMWAY, AND THE WORKING COST PER CAR MILE.

Line 3 miles long, double track (6 miles); generating ation as central as possible; five minutes' service at isiest time; average speed seven miles per hour, including oppages; cars to accommodate 40 passengers each; aximum number of cars running at one time, 10; h.p. per car, 10; total e.h.p. at station (50 per cent. serve), 180.

Permanent Way.	
ltering existing track to suit Gordon system, six miles at £2,000 per mile	£12,000
Rolling-Stock.	
itting 14 cars with motors, gearing switches, etc., (four cars in reserve), 14 at £150 each	2,100
Central Station.	
hree sets of steam dynamos, boilers complete, each capable of developing 60 e.h.p. (one set in reserve), buildings, foundations, switchboard, cables, instruments, etc.	5,400
	£19,500
ess stud of 100 horses and harness, at £35 each	3,500
Increased capital	£16,000
Running Expenses.	
Vages at central station	£364
Vorking electrician	156
uel	854
Vater, oil, waste, etc.	120
Depreciation and Repairs.	
/3 generating plant at 5 per cent.	£150
earing, etc., on cars, 40 per cent.	108
lotors, 25 per cent.	250
rack, 7 per cent.	840
uildings at 2½ per cent.	10
ontingencies, say	250
	£3,102

llowing an average of 80 miles per car per day, the total umber of car miles per annum $= 80 \times 10 \times 365 = 292{,}000$.

$$\frac{£3{,}102}{292{,}000} = 2{\cdot}55\text{d. per car mile.}$$

Horse traction costs about 6d. per car mile = £7,300
Saving by electric traction £4,198, giving a dividend on ncreased capital of £16,000 of 26 per cent.

Taking the present capital at	£35,000
Increase of capital	16,000
Total	£51,000

On which the saving by electric traction of £4,198 would give a dividend in addition to that now paid of 8 per cent.

TELEPHONES.

At the end of this month there will be a general hake up and awakening in the telephone world. Everybody is anxious to know the exact position of affairs. We have in this issue endeavoured to put the whole matter straight, to show what patents expire, to show what patents are still alive and controlled, and to estimate the value of such control. Practically, the conclusions of the well-known authority who has carried out this investigation on our behalf is that telephony will be released from its trammels. With the exception of a few unimportant details, which are still secured by patents, and outside of which excellent transmitters can be made, the world can make free use of the acquired knowledge in telephony. We are glad this is so, for in our opinion no monopoly has ever been worked less creditably than this of the telephone. Years ago we hinted that those most deeply interested in the company-mongering part of the business, would be found at the time of the expiration of the patents to have made hay while the sun shone, and have left the affair with pockets well lined, but with none, or very few, shares to their names. Of course, from one point of view, their action was and is amply justified. They started to make money. They made it. From our point of view we require a good telephone system, and a good service, at a reasonable rate. The shareholders deserve a moderate return for their investment, but the paying public do not wish to contribute to watered capital, watered for the purposes of company promotion and Stock Exchange transactions. That in London, at any rate, there is neither a good system nor a good service, will be gathered from the fact that so late as June 10 this year a circular, issued from the "London Chamber of Commerce," invites the combination of telephone users to obtain "increased efficiency and a reduction in rental." The circular states that "dissatisfaction has long been felt by many subscribers to the telephone company in London," etc. This company, instead of moving heaven and earth to please its customers, is finicking with advertisements cautioning people that it still controls various patents. No one need be frightened by this game of bluff. It is an ingenuous attempt to presume upon the ignorance of mankind. The stake, however, is too valuable for the whole question not to have been thoroughly investigated. It may be assumed also that by this time the Government knows its mind, and realises that unless the existing companies—as some of them undeniably do—give an efficient and fairly cheap service, it must undertake the duties and the responsibilities of its telegraphic monopoly.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

BATH.

SIR,—Having seen Mr. Hooker's letter in your last issue with reference to the Bath central station, I beg to say that up to the 30th January no alterations of any moment had been made by me; and that therefore any credit due for the state of the station at that time is due to him.

Had I seen your issue of 30th January, I should have

corrected your statement at the time, Mr. Hooker having done all that lay in his power to hand over the station in good running order.—Yours, etc., MARTIN C. OLSSON.

Bath, July 5, 1891.

JAN VAN BEERS AT THE CONTINENTAL GALLERY.

Something very choice and dainty and artistic took place in the small hours of Wednesday night, in the shape of a "souper artistique," by M. Jan Van Beers, as a "welcome" to his friends and patrons in England, and the function was carried out in a way that will make it long linger in the memories of those who were invited. M. Jan Van Beers is a most clever, daring, and original artist, whose realistic and skilful effects place him as a kind of successor to M. Wiertz, of Brussels fame, and his finish and delicacy almost rank him as a second Meissonier. His undeniably humorous and fetching little picture, "My Friend, Mr. White," recently reproduced, gives an idea of the *verve* and interest he manages to put into his pictures. Something of the same kind of effect was embodied in actuality in his supper at the Continental Gallery, 157, Bond-street, and as this effect was largely due to the skilful use of electric light, this otherwise exclusively artistic gathering comes within our scope. Over a hundred guests sat down at the somewhat fanciful hour of half-past eleven, among the guests being the Duke of Marlborough, Lord Dorchester, the Marquis de Stacpoole, Mr. Aird and Signor Tosti, Mr. Alma Tadema, Mr. Thaddeus (the painter of Mr. Gladstone's portrait), Captain Annesley, Mr. Spielman (of *Black and White*), Mr. Harry Furniss, Mr. Clement Scott, and a large number of other celebrities. The Prince of Wales was expected to look in, but his engagements with the German Emperor prevented. M. Van Beers had designed and superintended the arrangements himself. The long dining-table—upon which looked down his enchanting little pictures—was strewn with a long garland of roses, and similar wreaths festooned the walls and ceiling, amongst which electric lights were hidden within white, golden, and pink artificial roses. The table itself, most artistically laid out, was of glass, covered with a fine damask tablecloth, and all along the under side were arranged some 300 incandescent lamps of various colours—white, yellow, green, and rose—which lit the table from underneath and suffused the whole with a glow as of a veritable fairy palace. Madame Melba, from the Opera, first sang, her voice sounding from behind the tapestry curtain. Miss Florence St. John afterwards sang a strangely pathetic ballad after the supper had commenced. The first dish was a fancy from "Sing a Song of Sixpence," and M. Jan Van Beers opened a "Nightingale Pie"—not a ogrish repast, but one that set free a host of little songsters, who fluttered about and sang at intervals the rest of the evening. After which, the supper proper—with its "saumon à la Française, zephirs de Volvaille, chaufroix d'Ortolans, salade Byzantine, Nougat Chantilly, Pommery Greno," etc., with the fruit served in glittering dishes, around which tiny lamps glowed and twinkled. All the while, at intervals, the lamps changed, the table glowed up like the dawn from pale pink to pure white, and died away again; changeful effects innumerable succeeding each other continually, interspersed with violin and 'cello solos by M. Hollman and M. Van der Straten, as well as delicate concerted pieces. Presently the white ceiling became suddenly illuminated, and a series of political cartoons from *Vanity Fair* and elsewhere were projected with most amusing effect, stretching down the ceiling. Mr. Aird made a little speech, thanking M. Van Beers for his entertainment, and M. Van Beers himself, speaking in English, hoped his friends and patrons had enjoyed his "*petite fête*," and trusted next year to welcome the ladies as well. It only remains to add to this account of a remarkably successful entertainment that the electric installation for the gallery, consisting of 575 incandescent lamps, was fitted up by Messrs. C. Mellier and Co., artistic decorators, of 48-50, Margaret-street, Cavendish [illegible], under the superintendence of Mr. W. Lowr[illegible], engineer, who carried out the unique task of lit[illegible] the whole in one day with four men, setting [illegible] transformer also, which provided the current [illegible] Grosvenor circuit.

TRAMWAY COMPANIES AND ELECTRIC TRACT[ION]

Whilst electric tramways, or, as they are more [illegible] termed, electric roads, have been largely developed [illegible] United States, in England nothing beyond experim[ental] work has as yet been done in this direction. T[he] difficulty has been to induce the directors of [illegible] tramway companies to take an interest in modern [illegible] of propulsion. The first time that the subject of [illegible] traction was brought prominently under the notice [illegible] tramway companies in this country was on the occa[sion] the annual meeting, which took place a year ago, [illegible] Tramways Institute of Great Britain and Irela[nd] society to which belong nearly all the tramway com[panies] in the United Kingdom. At that time the interest [mani]fested in the subject was not very great, but [illegible] intimated that more consideration would be given [illegible] matter at the next assembly of the institute. The m[eeting] in question took place at the Westminster P[alace] Hotel on the 2nd inst. Mr. W. J. Carruthers-[illegible] managing director of the Birmingham Central Tra[mways] Company, etc., presided over the meeting, which [illegible] well attended. The chief point of interest was cent[red in] the reading and discussion of papers treating of the em[ploy]ment of electricity as the motive power of E[nglish] tramways. The papers read were on "The Lineff Sy[stem] of Electric Traction," by Mr. Gisbert Kapp; "Self-con[tained] Electric Tramcars," by Mr. A. J. Jarman; and [illegible] Gordon System of Electric Traction," by Mr. J. Go[illegible] Throughout the whole of the proceedings the tone [illegible] tramway men in conference was favourable to the [illegible] electricity, provided that agency could be shown [illegible] economical; and the result of the assembly, which [illegible] probably mark an era in the development of m[illegible] systems of locomotion, was the offer on the part of [illegible] tramway directors to allow of experiments to be cond[ucted] with electric tramcars on their lines for a sufficiently [illegible] period to demonstrate the practicability and comm[ercial] prospects of any particular system. Should the resu[lt be] favourable, the companies were prepared to adopt elec[tricity] as the means of traction.

Before the reading of the first paper was commence[d, the] president referred to the action of the National Tele[phone] Company on the occasion of the Birmingham C[entral] Tramways Company's seeking to get confirmed by P[arlia]ment its provisional order authorising it to use el[ectric] traction. This matter was dealt with in our leading co[lumn] last week, and the chairman stated that unless the de[cision] of the House of Lords Committee on the point [illegible] complete metallic circuit were reversed, another ob[stacle] would arise to retard the progress of electric traction.

In the course of his paper on the Lineff system [illegible] Kapp referred to an improvement which had been ef[fected] in the underground conductor, and by means of whi[ch the] insulation resistance of the line had been greatly augm[ented]. Originally the conductor touched the bottom of the ch[annel] throughout its whole length; the improvement consis[ted in] the use of a copper trough as the conductor, and supp[orted] at intervals on insulators. This method had increase[d the] insulation from 4,475 ohms per mile, to an avera[ge of] 35,000 ohms, and he believed that even this could be further augmented. Moreover, by the provision of [illegible] at suitable intervals, the iron strip could be withdraw[n for] renewal or cleaning without disturbing the surface [of the] street.

During the discussion Mr. Sturgeon, of Chester, sai[d] he doubted the practicability of the Lineff system ow[ing to] the lack of a solid connection between the sectional ra[il and] the car. He thought there must be a great loss of [illegible] in slowing down or stopping the car.

Mr. A. Dickinson, of Darlaston, was of opinion th[at it] would not be possible to prevent water and dirt [illegible] [g]etting to the conductor, and that if water in suff[icient quant]ity c[ollecte]d in the conduit, a great loss of c[illegible]

.d take place through its forming a conducting means he earth. In Boston, where a conduit 3ft. deep had used, it was found impossible to keep out moisture and This caused such a great leakage that the system to be abandoned, and he did not think that in the ff system, with a smaller conduit, that difficulty could ercome.

r. A. Reckenzaun, after referring to commercially essful electric tramways on the Continent, said that onsidered the insulation tests on the short line at wick were practically valueless. If the Lineff system laid down in a street where heavy traffic prevailed, pined that the passage of heavy carts would disturb conductor, and perhaps crack the insulating channel. er might then enter and seriously damage the insulation.

r. W. J. Carruthers-Wain said that in the United es electricity as the motive power was advantageous to the tramway companies and the travelling public, that many companies were transforming their lines electric tramways. The cost per car mile of working ble line in the States was 6·77d.; an electric road, d.; and a horse line, 8·71 per mile run; thus showing vour of electricity. He asked for particulars regarding initial cost of the generating plant for the Lineff em, and the estimated cost of working. Referring to storage battery cars in Birmingham, as the year's king had only just been concluded, he was not in a tion to state the operating cost. The introduction of e cars had, however, had a remarkable effect notwith- ding the difficulty of the track being bad on that icular line. During the year ending June 1889, with e cars, the number of miles run was 134,000; the l receipts, £6,338; and the receipts per car mile, 3d. In 1890, when the line was worked by horse and omnibuses, the mileage attained was 136,000, receipts, £5,264; and per car mile, 9·29d. In the year terminated, with storage battery cars, the number of s run was 148,000; the receipts, £8,949; and per car , 14·46d.

fter Mr. Kapp had replied to the discussion, Mr. Jarman a paper on his system of accumulator traction, which described in our issue of the 10th October, 1890. Mr. man exhibited his improved storage battery, which was described in a previous issue. The alloying of aluminium h lead in the plates of this cell stiffens the plate and eases the capacity of the negative plate to absorb and in hydrogen. The author stated that he had not found plates buckle at any time when discharging up to 300 peres, and he believed that the cells would bear at least as many more discharges as those now in use before renewal of the positive plates was necessary. He ted that accumulator cars could be operated so as to npete advantageously with horse traction. In this nection, the consumption of fuel, wear and tear of chinery, and renewal of batteries on the system was imated not to exceed 2d. per car mile.

Mr. W. Mason, of Bradford, said that accumulator cars ly would be successful. The great thing was, "what can u do it at, and will it pay?" He wanted a more nomical method of traction than that by horses, and y would all be happy to substitute electricity if it were ter.

Mr. G. P. Bradford, of the North Staffordshire Tramways mpany, said they wanted a system to improve upon am locomotion. He would be pleased to allow experi- nts to be made on his tramway. What they required s practical proof of the commercial prospects of electric ction.

Mr. Scott-Russell referred to accumulator traction nerally, and stated that all trials made hitherto had been lures from a financial standpoint. He, however, believed the accumulator system for this country, and said that cost of working the Barking cars was 7d. per car mile, d of those in Birmingham 10d. per car mile. Unless Mr. rman could show that his car could be operated within lf that figure, he feared that the system would be no re successful than previous methods.

Mr. Carruthers-Wain said what they all required was the ult of practical work on a reasonably long line and tended over a considerable period; experimental runs on short lines or occasional trips on long lines were not of much value. In addition to the offer made by Mr. G. P. Bradford, he (the speaker) and Mr. A. P. Smith, of Manchester, were prepared to allow of experiments being conducted on their tramways. He had in mind several lines where any system would be welcomed, provided electrical engineers would profess their belief and stand or fall by it. Although he was the managing director of the Birmingham Central Tramways Company, he had as yet been unable to ascertain the cost of working, and it was a mystery to him how Mr. Scott-Russell obtained the figure mentioned.

Mr. Jarman having replied to the discussion, Mr. J. Gordon read a paper describing his system, which has not previously been described at any length. We therefore give this paper:

THE GORDON (CLOSED CULVERT) SYSTEM OF ELECTRIC TRACTION, AND DETAILS OF EXPERIMENTS AT MERRYWEATHER AND SONS' TRAMWAY WORKS, GREENWICH, S.E.

Almost since the introduction of street tramways the general desire of engineers and managers has been to replace animal by some kind of mechanical traction. Both the steam engine and the cable have had a fair trial. As is well known, the steam tramway is fast becoming a thing of the past, and it is admitted by even the strongest supporters of the system that cable haulage is more economical than other systems only on short lines with steep gradients. There is no limit to the steepness of line which a cable car can climb, but on long lines, with only moderate gradients, the advantage possessed by the cable system disappears on account of the large amount of power required to keep the cable itself in motion, this power being, of course, waste. There is thus a most promising field open for the application of electricity to the propulsion of tramcars.

The electrical engineer who tackles this problem to-day has a much easier task before him than the pioneers in this work had a few years ago. He can go to the open market and purchase dynamo machinery which is practically perfect, as well as excellent and reliable electromotors. No doubt a slow-speed motor, the armature of which could be keyed directly on to the axle, and which would not be too heavy, is highly desirable; but the use of noiseless speed reducing gearing overcomes this want in a perfect satisfactory manner.

Seeing, then, that the electric current can be so efficiently produced at the power depot, and again transformed into mechanical power on the car, it seems strange that electric traction on tramways has made in this country so little progress. The difficulty lies, or has lain, in the means of conveying the electric current generated by the dynamo at the depot to the electromotor carried by the car. The method by which this is to be effected must not be too costly to install, must be efficient in working, and not liable to break down, must offer no obstruction or inconvenience to the general traffic, and, even if currents of low potential be used, there must be no possibility of persons or animals—especially horses—coming into contact with a charged conductor. Moreover, the installation must not be liable to objections on æsthetic grounds.

There are four well-known methods of conveying the electrical energy from the central station to the motor or the car.

The Storage System.—In this system the electrical energy generated at the station is there supplied to electric accumulators or storage batteries, and these, when fully charged, are placed on the car, and supply to the motor the current required. This system possesses the great advantage that it can be applied to existing tramways without any alteration in the permanent way, provided the latter has been built sufficiently strong to stand the great weight of these cars and the increased wear and tear.

Unfortunately, however, the system is very costly both to install and in running expenses. The highest technical skill, backed by almost unlimited money supplies, has been employed on the subject for years, and although very great improvements have been made, and a very excellent battery for stationary work produced, we are still without a satisfactory battery for tramway work, and until one has been evolved much more nearly fulfilling the necessary requirements, traction by means of accumulators cannot, from a commercial point of view, compete with horses.

Overhead System.—In this system bare conductors are led overhead from the central station along the whole length of the track, and connection is made between this and the motor on the car by means of a pole attached to the roof of the car by means of a sort of universal joint, and carrying at its upper end a collector which rolls on the under surface of the overhead conductor as the car moves along. Both from an engineering and a commercial point of view this system is the best of all, but, taking other considerations into account, it has serious drawbacks. The unsightly poles and cross-arms erected along the street are an eyesore and inconvenience to the public, and all the objections against overhead telegraph and telephone lines apply with much greater force to overhead tramway lines, and the breaking of a conductor in a crowded street might be attended with fatal accidents.

In America numerous lines of considerable mileage have been installed on this system, involving an enormous amount of capital, simply because it was the best system available. The results from

or yards, and the other over distances reckoned by ısands of feet, or even by miles. When we speak of the tric transmission of power, we tacitly assume that it belongs ıe latter class, and refers to distances beyond the reach of the ınary gear, such as shafting, cogwheels, pulleys, and belts, ıloyed for the subdivision and distribution of power within walls of a factory ; and it is in this generally accepted sense I propose to bring the subject mainly before you. There however, cases where the application of electromotors to ıial tools is either the most convenient or only possible hod of applying mechanical power to the performance of ain operations, and it will, therefore, be necessary at least ıtly to glance at that part of our subject which is not usually ıprised within the title of these lectures—namely, the transsion of power over very short distances by means of electric rents. We thus distinguish between "long distance" and ıort distance" transmission, the fundamental distinction ween the two being that in the former the transfer or transsion of power from one point to another, so to speak, in k, is our main object, whilst in the latter we rather aim at subdivision and convenient application of power, in small ıntities, at various points, and for particular purposes. I ıpose to consider long-distance transmission first.

Broadly speaking, there are two ways in which we can nsmit mechanical energy from one place to another. Let assume, by way of example, that the primary source of ergy is coal, and that the power derivable from this coal is quired, not at the pit's mouth, but at a mill a certain number miles away. In such a case the obvious, and also the most nomical, way of transmitting power is to carry the coal to mill, and burn it under the boiler of the mill engine. Even he distance between the pit and the mill is short, this method ll be the best, provided there are no difficulties of transport. ppose, however, that, although the distance is short, local nditions, such as great difference of level, bad roads, or total sence of roads, render the carriage of coal difficult or imposle, then we would establish our boiler and engine at the pit, nerate the power there, and transmit it by wire rope, or in ne other way, to the mill. In both cases we have transmission power, but the methods are essentially different. In the t case we have transmitted, not mechanical energy itself, the thing from which mechanical energy can be obtained, nely the coal, each ton of which represents so many stored rse-power hours. In the second case we have transmitted energy itself in its kinetic or potential form. In popular guage we might describe the process as the transmission of ive" power, as distinguished from the transmission of tored" power, which takes place when we carry coal from pit's mouth to the mill.

The most important sources of power in nature are corn, coal, d falling water. Under the term "corn" I comprise all getable food-stuffs suitable for conversion into mechanical ergy, by means of horses and other animal engines ; whilst term "coal" naturally includes all kinds of fuel suitable conversion into mechanical energy by some form of heat gine. The power derived from corn and coal is generally nsmitted in the stored form ; that derived from falling water the live form, since the conveyance of water at a high level, under considerable pressure, to great distances necessitates e erection of very costly works. To prevent misunderanding, I must here point out that I use the term "stored ıergy," as applied to water, merely in its colloquial nse. We speak of the energy stored in the water of a ill-pond, but, in reality, the energy does not reside in he water at all, but is an effect of its elevated position, and , therefore, not comparable with the energy which is chemially stored in coal. Leaving, however, such distinctions on ne side at present, we may regard water, which is being carried long horizontally, at a certain elevation, from one place to nother, as the vehicle of so much stored energy, which we can btain in its live form at any point at which we establish a vater engine, through which the water passes in its descent to a ower level. If we carry water along in this way, it is not with he object of bringing the stored power to the point of applicaion, but merely to secure the largest possible fall, and, therere, a maximum of power with a given quantity of water. If be necessary to transmit the power farther, the transmission generally effected in the live form. Now let us see what osition electricity occupies in relation to these primary sources power in nature—namely, corn, coal, and falling water.

In the first place, it will be obvious that, where electricity is he transmitting agent, we can effect the transmission both in e stored and in the live form. To see this clearly, we need ıly for a moment revert to our example of the coal pit and the ill. Instead of sending the coal to the mill to be converted to power there, we could burn it at the pit, and thereby nerate steam to be used for driving a steam dynamo. The ırrent from the dynamo we could utilise in charging a storage ttery, and send this to the mill, where it would drive an ectromotor, thus taking the place of the local steam engine. ere we have a system of transmitting energy in the stored rm. On the other hand, if we do away with the batteries as a vehicle of energy, and connect the dynamo at the pit with the motor at the mill by a pair of insulated wires, we have a system of electric transmission of power in the live form. The latter system is that generally understood under the term "electric transmission of power," and therefore forms the principal subject of these lectures ; but before entering upon it, I propose briefly to investigate the capabilities of electric transmission of power in the stored form.

As you all know, a sack of coal contains more storage power than a secondary battery of equal weight, and its carriage, whether by rail or road, is cheaper, easier, and requires less precautions than that of the battery. It is, therefore, quite obvious that, if the primary source of power is coal, and if there is no objection to the establishment of a steam engine at the place where the power is wanted, it will be more economical to carry the power there in the form of coal than in the form of batteries ; not only because of the saving in carriage, but also on account of the smaller capital outlay, the smaller depreciation, and the avoidance of the loss of energy in the battery itself. But let us assume that the primary source of energy is falling water, then it is not so obvious at the first glance that its electric transmission in the stored form should be uneconomical. We cannot produce coal out of the energy of falling water, but we can charge batteries with it, and electricity would thus seem to offer a means of utilising a power of nature which would otherwise be lost. It might, perhaps, here be objected that electricity does not form the only means for utilising such a power, since there are various other ways in which power may be stored, a familiar example being compressed air. We might, therefore, also utilise the power of the waterfall for working an air compressor, and store the air under pressure in steel reservoirs, to be used afterwards for working air engines constructed similarly to ordinary steam engines. Many such engines are actually in use in Paris on the Popp system, though there the air is conveyed to them by pipes under pressure, and not in storage vessels, as would be the case in our example. There can thus be no doubt that the transmission of power by stored air is practicable, but the question is at what cost will it be effected, and can it compete with transmission by batteries? The answer to these questions depends on two factors—namely, the storage efficiency, and the cost of transport. By storage efficiency I mean the ratio of the power put into and taken out of the apparatus which serves as the vehicle for the power. Batteries may now be obtained in which this ratio is about 80 per cent.—that is to say, for every 100 horse-power hours put into the battery, 80 horse-power hours can be taken out. The storage efficiency of compressed air is very much smaller. The most reliable data under this head are to be obtained from the paper which Prof. Kennedy read before the British Association in 1889, when he gave an account of experiments carried out at Paris on the Popp system. He found that the indicated efficiency with cold air was 39 per cent.—that is to say, for every 100 h.p. indicated by the compressing engine, 39 h.p. were indicated in the engine driven by compressed air as it came from the mains. If the air before being admitted to the engine was heated to 320deg. F., the apparent indicated efficiency rose to 54 per cent., but as the heat energy thus supplied to the air requires the expenditure of fuel at the point where the power is wanted, the use of hot air really involves two methods of transmission—namely, that of power in the shape of air under pressure flowing through the mains, and that of power in the stored form contained in the fuel. To make the comparison with electric transmission of stored power a fair one, I must therefore take the efficiency of the Popp system when the air is not heated. A correction must, however, be made for loss of power in the mains. In the Popp system the power is transmitted in the live form by air flowing through pipes, and there is necessarily a certain loss on account of friction in the pipes and valves. As far as the friction in the pipes is concerned, this would not occur if the transmission were effected in the stored form by means of air carried under pressure in a reservoir, but, on the other hand, the loss by friction through valves would be greater, because it would be necessary to insert between the reservoir and the air engine a reducing valve, which would regulate the supply of air as the pressure falls. The loss of power due to this circumstance will probably be greater than the corresponding loss in the Popp system, where the pressure is constant ; but as I have no experimental data to determine this point, I take the same loss as found by Prof. Kennedy—namely, 2 per cent.—which makes the indicated efficiency nearly 40 per cent. The efficiency of the air engine he found to be, with cold air, 67 per cent., making the total efficiency of the system 26·7 per cent. By adopting air storage we could therefore obtain $26\frac{3}{4}$ horse-power hours for every 100 horse-power hours indicated in the engine. Now let us see how the case stands with electrical storage. The efficiency of the steam dynamo—that is, the ratio of the electrical output to the indicated power—may be taken at 83 per cent. ; that of the batteries 80 per cent. ; and that of the motor at least 85 per cent. ; so that the total efficiency works out to quite 56 per cent., or more than twice that of the rival system. I have here assumed that the dynamo is steam driven, simply because the only reliable figure

I could obtain about compressed air referred to steam-driven compressors, but it is obvious that the comparison of the storage efficiencies of the two systems cannot be materially affected by the source of power, and will practically be the same in the case under consideration, where the power is supposed to be derived from falling water. We see that in efficiency, at least, air storage is far behind electrical storage. Let us now enquire whether it is any better off in the other essential feature I have mentioned—namely, in the cost of carriage. The information available under this head is tolerably reliable as regards batteries, but this is not the case as regards air stored under pressure. I know of no experiments made to determine accurately the weight of air reservoirs, and in the absence of such data I cannot do better than adopt the calculated figure given by Prof. Osborne Reynolds in one of his Cantor lectures delivered in 1888. According to this authority, the weight of the steel reservoir and air contained would amount to 300lb. for every horse-power hour so stored. Now, the weight of a secondary battery filled with liquid, and provided with a tray and connections, all complete, does not exceed 100lb. per horse-power hour stored—that is, only one-third the weight of an equivalent air reservoir. We see, therefore, that as regards efficiency, air storage is twice as bad, and as regards weight, it is three times as bad as electric storage. Competition with it is, under these circumstances, obviously impossible; and we may therefore say that if the transmission of power from the waterfall to a distant point has to be made in the stored form, electricity is the only agent which need be considered.

Whether it would pay so to transmit power is a question which cannot be answered off-hand. As compared with the direct transmission of live power by means of a pair of wires, the cartage of batteries up and down the country will no doubt appear to be a clumsy device, but when we are investigating the different possible solutions of an important problem we must not allow any preconceived opinions of what is elegant or clumsy to influence our judgment—we must, in fact, judge each case on its own merits, and I propose to deal with the electric transmission of stored energy in this sense. The system of power transmission by storage batteries is actually in use, not, indeed, for long-distance transmission pure and simple, as above defined, but still for transmission over distances reckoned by miles. I allude to the electric tramcars worked by storage batteries which are charged at a central depot, and run for many miles before they require to be again charged. The object is not to carry a certain amount of power in bulk from one point to another, but to dispense whatever power is required for the propulsion of the car during the journey. We might, however, imagine the tramcar, instead of being occupied by passengers, to be loaded with storage cells in addition to those it carries for its own propulsion. Whilst the latter would gradually lose their charge in transit between the two terminuses, the former would arrive fully charged, and could be made to give up part of the power stored in them at the starting point. Here we have transmission of power in the stored form, but let us return to our example of the waterfall and the mill, and see how such a system might be put into operation.

At the waterfall we establish the necessary hydraulic works, and an electric station where the batteries can be conveniently charged. We further build a tram line or railway, joining the charging station with the mill where the power is wanted, and we design the rolling-stock with special regard to the safe and convenient carriage of the batteries to and fro. The train is fitted with electromotors, so as to make it self-propelling. A trainload of charged cells is thus taken to the mill, and left there to work the electromotor which supplies power to the mill. During this process the batteries becomes gradually exhausted, and must be disconnected from the motor before they are quite exhausted, because we must allow a sufficient margin of power for taking the train back to the charging station. The economy of the whole system will evidently be the greater the less power is spent in the outward and home journey; and we might call "efficiency of transmission" the ratio of the power actually delivered to the motor, and that which might be so delivered if the battery were used for working a motor at the charging station itself: in other words, if the distance of transmission were nought. Say, for instance, that a total of 1,000 horse-power hours could be obtained from the battery, if it were discharged immediately, and that the power spent in the outward journey amounts to 50 horse-power hours, then a further 50 horse-power hours will have to be spent in the return journey, and the power obtainable at the mill will only amount to 900 horse-power hours. The efficiency of transmission will in this case be 90 per cent. If we double the distance between the waterfall and the mill, the efficiency of transmission would be reduced to 80 per cent. If we trebl[illegible] distance, the efficiency would only be 70 per cent., and so [illegible] ficiency must naturally depend on the kind of road [illegible] transmission takes place. [illegible] be small on a com[illegible] ad, larger on a tramw[illegible] ll on a railway, [illegible] a canal. We can, f[illegible] gement, expr[illegible] the system, as far [illegible] ower is conc[illegible] two ways. We can, if the distance is fixed, give the [illegible] in the usual way as a percentage, or we can fix a standard [illegible] centage of efficiency, and ascertain the distance over which [illegible] standard is attainable in any particular case. I shall adopt [illegible] latter way of reckoning, as the more convenient for comp[illegible] with other methods for transmitting power, whether [illegible] stored or live form.

First, as to transmission of stored power otherwise th[illegible] batteries. The only two methods we need consider [illegible] carriage of corn and the carriage of coal, each combined [illegible] the use of a proper engine for converting the stored [illegible] power at the other terminus of the line of transmiss[illegible] the case of corn, the starting point of this line is the [illegible] where the corn is grown. We there load it into suitable [illegible] and send it to the mill where the power is wanted. [illegible] are dealing now entirely with animal power, we must [illegible] the cartage to be effected by draught animals, say horse[illegible] the conversion of corn into live power at the mill also by [illegible] animals.

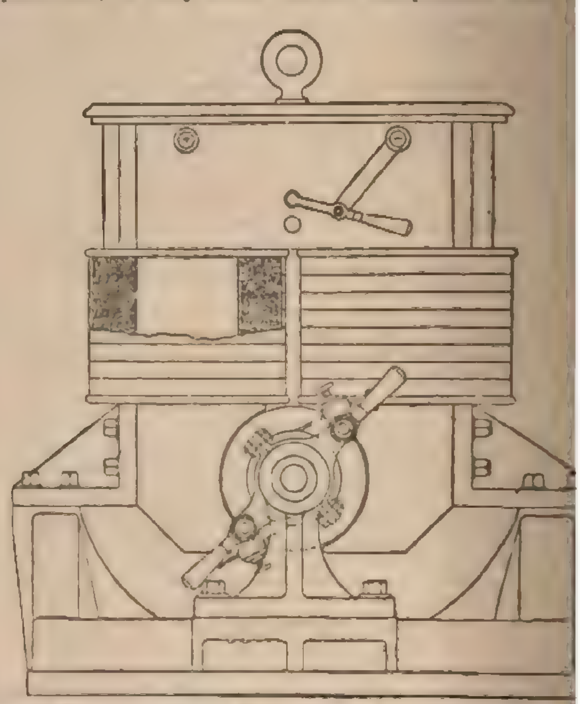
(To be continued.)

THE ELECTRIC LIGHTING OF PUBLIC BUILDI[illegible] WITH SPECIAL REFERENCE TO THE ATHENÆ[illegible] ELECTRIC LIGHT INSTALLATION.*

BY PROF. JAMIESON, M.INST.C.E., F.R.S.E.

(Concluded from page 21.)

Mr. M'Whirter said that Kapp gave as a safe armatur[illegible] 1,000 ampere-turns for each 1in. diameter – 5in.; call the di[illegible] of this armature 14in., then by Kapp's rule it should ca[illegible] ampere-turns, or only about one-half its present load.



Faraday Dynamo. Single Field—Vertical. 18 Units at 500 [illegible] lutions. (Designed by Mr. M'Whirter, see last week's *E.E.*, [illegible]

would be more in harmony with everyday practice, and att[illegible] by better results. How these were ever made for an out[illegible] 26 units at 600 revolutions (as they were originally) wa[illegible] than can be easily explained, and, in fact, was more work tha[illegible] ever did in anything like a satisfactory manner. Prof. Ja[illegible] had entirely left out a very important point. He said n[illegible] at all about the heating of those machines. Now, as [illegible] were put forward as ideal machines for public lighting, th[illegible] a point of very great importance, and ought to be thor[illegible] discussed. The heating of field magnet coils was easily calc[illegible] from the formula given by Esson at the Electrical Enginee[illegible] was of course directly as the watts lost in the coils, and inv[illegible] as the surface available for the radiation of the heat[illegible] ultimate rise of temperature in degrees centigrade was gi[illegible] the equation

$$C\text{deg.} = \frac{W \times 55}{S}$$

where W was the rate at which energy was to be dissipated in [illegible] S the cooling surface in square inches, and 55 a constant for [illegible] cotton covered and varnished wires on field magnets. Tak[illegible]

* [illegible] ssion on paper read before the Institution of En[illegible] an[illegible] ders in Scotland, *vide E.E.*, May 1, 8, 22, 1891.

dimensions of the magnet coils as 12·75in. diameter, the length as 0·5in., then they had

$$C\text{deg.} = \frac{1{,}017 \times 55}{840} = 60\text{deg.};$$

and this added to the temperature of the engine-room, which might reasonably be taken as 20deg., would bring up the temperature to something like 87deg. C., a condition not at all favourable to a long life for any machine. If, however, they applied the same test to the dynamos called Nos. 1 and 3, a reasonable voltage for charging 58 cells would be 140 at the terminals of the dynamo. The resistance being taken at 11·5, then they found that

$$C\text{deg.} = \frac{1{,}711 \times 55}{840} = 112\text{deg.}$$

He was very pleased to see, from the remarks made by the author, that there was a likelihood of his being able to add to the paper the whole particulars of tests; and he felt sure that this would make the paper of considerable value.

Mr. W. B. Sayers said the title of the paper would lead one to expect a fairly comprehensive treatment of the subject of lighting of public buildings by electricity, but unfortunately this was by no means found to be the case. Notably there was nothing in the paper about the way in which the wiring of the building should be carried out, or information as to how it had been done in the case of the Athenæum. He had taken advantage of Prof. Jamieson's offer, and had viewed the Athenæum installation; and he should like to ask Prof. Jamieson to state whether the information that there were no fuses employed except in the switches and ceiling roses, and in the mains at the switchboard, was correct? If this were so, a considerable length of the branch wire must in each case be unprotected by any except the main fuses, which were far too heavy to break before a branch wire became dangerously overheated in case of a short-circuit—a state of things which no fire insurance inspector up to his duty would or indeed ought to pass. Everyone who had had to do with the lighting of large spaces by means of incandescent lamps, would agree with the author of the paper as to the excellence of the Sunbeam lamps for this purpose. The space covered in by the Caledonian Railway bridge in Argyle-street was a good example of this. It was lighted by nine 200-c.p. Sunbeam lamps—the lamps forming part of the large installation which had just been completed by Messrs. Mavor and Coulson in the Caledonian Central Station and Hotel, which were now lit throughout by electricity. As Mr. Mavor dealt with Prof. Jamieson's statement that it was necessary to increase the pressure as the lamps got older, he would only point out two obvious ways of dealing with old lamps, and those adopted at the Central Station, which were (1) to move the old lamps into lavatories and places where small light was sufficient, and (2) to move them to places nearer the dynamo or source of supply, as there would generally be three or four volts difference of pressure between the two ends of the distributing cables and wires. The fact that he found triple expansion Westinghouse engines in use at the Athenæum, and that, while no mention of these was made in the paper, a compound Westinghouse engine was illustrated on the sheet, led him to enquire whether the table given in the paper showed the results of actual tests with the triple expansion engines, or forecasts of the expected results when these had been replaced by compound engines, which he understood was in contemplation. Prof. Jamieson, in his reply, stated that the tables were the results of actual tests, which statement he (Mr. Sayers) of course accepted; but it would be interesting to hear the explanation of the discrepancy between what actually existed and the illustrations in the paper in the matter of the engines. It would be a distinct advantage to run up a light partition to divide the engines and dynamos and switchboard from the boilers, in spite of Prof. Jamieson's arguments in favour of having them all in one compartment. This view, which he took from first seeing the paper, was emphasised when, on looking at the switches, and thinking they were somewhat light for the current they were said to carry, he ventured to touch the contact of one of them, and got his finger burned for his pains, although the current passing at the time was only 80 amperes, the switches being supposed to be capable of carrying 200 amperes. This heating was due partly no doubt to the switches being light, but also to their having the contact spoilt by the fine dust and grit which covered everything.

Prof. Jamieson said that as the time was so late (10.15 p.m.) he would answer the various speakers in writing. He was glad that so many points had been touched upon in the discussion, and he would endeavour to combat the different objections that had been raised to his views as expressed in the paper.

The **President** said he thought it must be apparent to everyone that Prof. Jamieson had, according to his light, devoted a great deal of attention to this subject in a thoroughgoing manner, and he had spent a great deal of time over it; and, therefore, the least they could do was to accord him a very hearty vote of thanks.

The vote was heartily accorded.

Prof. Jamieson sent the following reply in writing: Referring to Mr. Thom's remarks regarding high *versus* slow speed engines, the author was well aware of the increased economy derivable from working with a high piston speed. He had tested many engines of different kinds for the consumpt of steam per indicated horse-power and per boiler horse-power. In fact, it was only a day or so before that he had occasion to test a novel kind of rotary steam engine invented by Mr. Brown, of Swindridgemuir, Dalry, Ayrshire, which engine gave a consumpt of 47·5lb. of steam per boiler horse-power hour when run at 274 revolutions per minute, but over a continuous five hours' trial the consumpt was reduced to 37·9lb. steam per boiler horse-power hour when run at a mean speed of 574·5 revolutions per minute. This worked out about 27lb. per indicated horse-power from the indicator cards, taken with M'Innes indicator. The cylinder of this little rotary engine measured only 10½in. diameter by 8⅝in. deep, of which nearly one-half of the volume of the cylinder was occupied by the revolving piston, and it developed a mean of 20·78 boiler horse-power, with steam of 80lb. pressure per square inch in the cylinder.

The author was, however, glad to see that Mr. M'Whirter agreed with him in regard to the advisableness of employing, under certain circumstances, engines with a fairly long stroke, and fewer revolutions per minute, than those with a great number of revolutions per minute. It was not altogether a case of steam economy that the electrical engineer had to consider, for he had to take all these circumstances into account when ordering engines, and to weigh carefully how the total expenses would stand at the end of, say, one, two, or more years.

Mr. M'Whirter, near the commencement of his remarks, referred him to the discussion which took place at the Institution of Electrical Engineers on Prof. Forbes's paper (not last year, as stated by Mr. M'Whirter, but March 14th, 1889) on "Some Electric Lighting Central Stations and their Lessons" for the consumpt of steam by Willans's engines. He had looked up the *Proceedings* of that Institution, and found that Willans's engines were not referred to there in this light; but Mr. Robinson, the partner of Mr. Willans, said (at p. 229, *Proc.* Inst.E.E.), in reference to Prof. Forbes's hearsay statements regarding a 400 h.p. compound Corliss condensing engine in the central station at Berlin, using only 15·5lb. of water evaporator per electrical horse-power hour: "One cannot but wish for detailed figures of such tests as these, and for fuller particulars generally. Certainly we cannot match such figures as in England yet . . ." "I have seen an English condensing engine giving an indicated horse-power upon 15·1lb. of water." It was, therefore, quite evident that Mr. M'Whirter was mistaken. The author would feel much obliged for any reference to any authentic case wherein the consumpt of steam in any slow or fast speed non condensing engine was less than 20lb. per hour per electrical horse-power, or 15lb. per indicated horse-power, since the double of those values were considered very good work. They must always take care, when speaking of the consumpt of steam per horse-power, that they knew exactly whether it was per indicated horse-power, or boiler horse-power, or electrical horse-power, for it made a very great difference to the results; also, whether the engine was a condensing or non-condensing one, or a simple compound or triple expansion engine.

Mr. Thom at the end of his remarks said, "It makes matters worse when you arrange the boiler to slide along the bottom." The boilers were not arranged as he supposed, but merely given freedom to cant over under the expansion of the steam dome. If the distance between the junctions of the boilers to the steam dome did expand $\frac{1}{4}$in., this would only mean $\frac{1}{32}$in. at the extreme ends of the two boiler seats, and here they had freedom to expand. Mr. Couper said: "In regard to the receiver which one gentleman had taken exception to, he might say that they did not approve of that either. They suggested a connection by a copper pipe, but Prof. Jamieson, as the consulting engineer, preferred a rigid connection, and went into the matter of expansion, to see how much expansion took place. . . ." This was not strictly true, for Messrs. Lindsay, Burnet, and Co., of which firm Mr. Couper was a partner, sent in their competitive tender, design and specification with rigid connections, without any suggestion or remarks *re* this point. Their tender was accepted, but before the firm began to make the boilers, he requested them to give him a design for a more flexible system of connections between the boiler and the steam dome. Their new design and extra price for this alteration was not accepted, for various reasons. The firm agreed to fit the connections with freedom faucet-joints, and to give further freedom from expansion in the different ways already mentioned. They thought, and all were agreed, that this would prove satisfactory, and as Mr. Couper remarked, "it had not given any trouble that he knew of."

To finish off the boiler question. Mr. Burnet, in his remarks, said, "One would have expected that a well-known public teacher like Mr. Jamieson would have treated this part of the subject in more exact language than to speak of horse-power of boilers without defining that horse-power in some way. The Athenæum boilers might be 60 of that unknown quantity, if you coaled them to that extent, but from Table IV. at that output, the heat efficiency was only 58·6 per cent." Mr. Burnet agreed in his tender to give them 60-h p. boilers, on the assumption that an indicated horse-power required 25lb. of steam per hour at 150lb. pressure. The Babcock-Wilcox Company always stated the power of their boilers as equivalent to 1 h.p. for every 30lb. of steam raised per hour at a certain pressure. He admitted the laxity of language used in this instance, more especially as the weight of steam (stated in Mr. Burnet's tender) per horse-power hour was lower than the general rule!

Mr. Burnet (as well as others) complained of the want of details in regard to the results given in Table IV. He should be only too glad to furnish these, but when they remembered how Mr. Burnet withdrew from the *Proceedings* of that institution the sectional drawings of the boilers and the feed water heater, which his firm had given him liberty to make use of for the purpose of this paper; further, when they learnt that he had offered to place his whole services at his disposal for a twelve hours' trial of the boilers in question, and that he declined to accept the same, he could not but gather that he (Mr. Burnet) wished to keep matters quiet. However, since he and others had requested figures, he had, as they would observe, given full details of how the boiler efficiency was arrived at, and now supplemented these by the following Table V., which showed the main dimensions of the boilers, and by Table VI.,

which gave one set of his tests most closely approaching to the contract tender for the two 60-h.p. boilers at 25lb. steam per horse-power hour. In this case, the efficiency was found to be 60·6 per cent., and as far as the mere steaming qualities of the boilers were concerned, he had no fault to find.

TABLE V.—DIMENSIONS OF THE ATHENÆUM BOILERS.

Type—Dry back tubular.
Number of boilers—2.
Diameter of boilers—5ft. 9in. inside.
Length of boilers—5ft. 9in. inside.
Number of tubes in each boiler—62.
External diameter of tubes—2½in.
Furnace tubes—length, 5ft. 9in.; diameter, 2ft. 6⅞in. internal.
Fire grate—length, 4ft. 3in.; width, 2ft. 6¼in. mean.
Grate area—10·8 square feet each; 21·6 square feet both.
Heating surface—In furnace, 30·6 square feet; in tubes, 233·3 square feet; total for both boilers, 528 square feet.
Height of chimney from firebars—110ft.
Sectional area of chimney—5 square feet.
Sectional area through tubes of both boilers—3·04 square feet.
Heating surface for each square foot of grate area—24·4.
Heating surface of feed-water heater—51·5 square feet.

TABLE VI.—DETAILS OF A TEST OF THE ATHENÆUM BOILERS.

1.	Duration of each test	5½ hours.
2.	Heating surface	528 square feet.
3.	Grate area	21·6 square feet.
4.	Coal burned per hour	355lb.
5.	" " per square foot of grate area	16·4lb.
6.	" " " " heating surface	·67lb.
7.	Water evaporated per hour	2,425lb.
8.	" " per square foot of grate area	112lb.
9.	" " " heating surface	4·5lb.
10.	" " per lb. coal at feed temperature	6·8lb.
11.	" " " 212deg. F.	7·58lb.
12.	Temperature of feed in tank	34deg. F.
13.	" leaving feed heater	145deg. F.
14.	Rise in temperature due to feed heater	111deg. F.
15.	Temperature of chimney gases	550deg. F.
16.	Chimney draught	1in. water.
17.	Calorific value of the coal in British thermal units	12,500.
18.	Pounds of water that would be evaporated from and at 212deg. F. with perfect combustion	12·5lb.

19. Efficiency of boiler (theoretical) $= \frac{7 \cdot 58}{12 \cdot 5} \times 100 = 60 \cdot 6$ per cent.

From another Set of Tests.

(1)	Coal (of above quality) per i.h.p. per hour (net)	4·7lb.
(2)	" " e.h.p. per hour (net)	6·7lb.
(3)	" " e.h.p. per hour, taking the amount required for the feed pump and the steam jet into account for 26 working days in February and March, averaged about	10lb.

Mr. Burnet said, "It would be of great interest here to know how a value was arrived at by Mr. Jamieson in making up his complete statement of cost of light to the Athenæum proprietors, as compared to equal light bought from a central station." This he had pleasure in giving by the following Table VII.:

TABLE VII.—COST OF RUNNING THE ATHENÆUM ELECTRIC LIGHTING PLANT.

From the Mean of 26 Working Days in February and March.

		Cost per day.		
1.	Coal, 56 tons, at 13s. per ton	£1	7	3
2.	Wages of engineers and fireman	0	10	1
3.	Oil, waste, etc.	0	0	9
4.	Water, at £4 per month	0	3	0
5.	Rent of engine-room	0	3	0
6.	Depreciation of plant, 12½ per cent. per annum on £2,500	0	17	1
		£3	1	2

So that the £3. 5s., or 4d. per Board of Trade unit, as stated on the diagram of the load curve, appeared to be more than sufficient for the case under consideration.

Mr. Burnet stated "that with the grate area as used at the trial, which was as much as one-sixteenth of the total heating surface, it would require great skill to prevent waste of fuel, and it would here be interesting to know if the forced draught appliance was in use at the time." The correct ratio of these quantities, as would be observed from Tables V. and VI., were—

$$\frac{\text{grate area}}{\text{total heating surface}} = \frac{21 \cdot 6}{528} = \frac{1}{24 \cdot 4}$$

Meldrum's steam forced draught was in use during this trial, and the firing was most skilfully looked after by a marine-going engineer. They had at the Athenæum as steady, reliable men to look after the boilers, engines, and dynamo plant as would be found anywhere; besides which he asked Mr. Burnet to bring with him the most skilful fireman he could get, in order to prove the results of their tests, and to make comparative trials with and without the forced draught, but he never came. *Re* the writer's remarks about right-angled bends and throttled passages, he certainly was impressed by the very poor draught, and the density of smoke from the old chimneys. This chimney, together with three ordinar[illegible] had been connected to the boiler's smoke-boxes, with a [illegible] angled sheet iron flue, by Mr. Burnet's firm. The pri[illegible] the failure was due, however, t[illegible] small cross [illegible] of the old chimney, with which, and the three ordinary fireplace [illegible] they had been requested to do their best. The vents did [illegible] well with the boiler chimney, and although a steam jet was [illegible] duced into each of these outlets (which so far helped the draug[illegible] in certain conditions of the atmosphere the draught was not [illegible] than a quarter of an inch of water pressure. It soon became [illegible] dent that this makeshift arrangement would not effect the des[illegible] object, and they therefore employed Messrs. Braby and Co. to [illegible] an iron chimney, with flues leading thereto having easy bends [illegible] large area, which now gave, under normal conditions, a draug[illegible] equal to one inch of water pressure.* The height of the top [illegible] this chimney was 110ft. above the furnace grates, and it was 2[illegible] diameter, or 4·9 square feet in cross area, instead of the [illegible] chimney, which was only about 75ft. high, and 2·1 square fe[illegible] cross area. The formula he used for the dimensions of the [illegible] chimney was:

$$A = \frac{2 \cdot 4\ G}{\sqrt{H}} = \frac{2 \cdot 4 \times 21 \cdot 6}{\sqrt{110}} = 4 \cdot 9 \text{ square feet,}$$

where A represents the cross area of chimney in square feet,
" G " surface area of fire grates in square fe[illegible]
" H " height of chimney in feet.

The draught obtained from this chimney was all that could [illegible] desired with or without the forced draught, but they were [illegible] with the local legal demand to make as little smoke as possi[illegible] Mr. Burnet suggested that they should still further diminish [illegible] length of the fire grates, and give up the forced draught. [illegible] would most undoubtedly again have brought them before [illegible] magistrate. They would try a smaller area of fire grate, so as [illegible] burn more coal than 16·4lb. per square foot of grate area, [illegible] ·67lb. per square foot of total heating surface, but most certa[illegible] they could not do so without the aid of the forced draught w[illegible] and for some time after firing, unless they were permitted to [illegible] black smoke with ordinary triping coal. One further advantag[illegible] the forced draught was, that it kept the boiler tubes so clean [illegible] they had only to sponge them twice a week.

Mr. Mavor objected to their method of increasing the voltage [illegible] the lamps got older. When, however, it was explained that at [illegible] beginning of the Athenæum's session a fresh set of lamps were in[illegible] duced into all the most important positions, that these lamps [illegible] rule lasted the whole year, and that should any of them give [illegible] before that time they were replaced by the best of the old la[illegible] previously taken out; further, the plan mentioned by Mr. Se[illegible] was also adopted as far as possible—viz., the oldest lamps [illegible] moved into unimportant places, or nearer to the dynamo[illegible] would be evident that they did not think "this method of [illegible] cedure utterly fatal to economical working." A convenient [illegible] was given by Mr. Thomas G. Grier, in a paper read recently be[illegible] the Chicago Electrical Club, and reprinted in the *Electrical Re[illegible]* of London on May 8, 1891, whereby they might calculate the [illegible] economical length of time which a lamp of a certain effici[illegible] could be used. The rule was as follows:

Let A = the number of watts required by a 16-c.p. lamp.
" B = the life of the lamp at (A 16) efficiency per c.p.
" Y = the cost of a 16-c.p. lamp.
" X = the cost of a watt-hour delivered at the lamp.

Then, the most economical time to run the lamp would be [illegible] the cost of the renewal plus the cost of the power is a mini[illegible]

Or, $\frac{Y}{B} + (X \times A) =$ a minimum.

Taking the case of the Athenæum, where the cost of a Boa[illegible] Trade unit, or "bot," was 4d., the cost of renewals (including [illegible] dental breakages, carriage, purchaser's risk, and interest) [illegible] per 16-c.p. lamp, it would be found most economical to ru[illegible] lamps for fully 1,200 hours before replacing them by new [illegible]

* It is only by relating failures as well as successes that we [illegible] true progress in engineering. I have therefore pleasure in comm[illegible] cating my experiences on this important matter of draught [illegible] smoke; more especially as I have for some years advocated d[illegible] the cross area of steam-pipes usually adopted, together with [illegible] easy bends. The formula which I have given for the cross ar[illegible] a chimney has a larger constant than that found in any [illegible] which I have come across, but, nevertheless, I do not think [illegible] too large for the height of chimney, and for multitubular b[illegible] where the gases experience considerable friction, due to the [illegible] and the number of bends round which they must pass.

† Let a 16-c.p. lamp require a mean of 60 watts for 500 hours' ligh[illegible]
" " 65 " 1,000 "
" " 67 " 1,200 "
" " 70 " 1,500 "

Then, from the above formula and data, we have

For 500 hours' lighting $\frac{48\ (\text{pence})}{500\ (\text{hours})} + \left(\frac{4}{1{,}000}\,(\text{pence}) \times 60\ (\text{watt[illegible]}\right.$ =

For 1,000 hours' lighting $\frac{48}{1{,}000} + \left(\frac{4}{1{,}000} \times 65\right)$ .... =

For 1,200 hours' lighting $\frac{48}{1{,}200} + \left(\frac{4}{1{,}000} \times 67\right)$ .... =

For 1,500 hours' lighting $\frac{48}{1{,}500} + \left(\frac{4}{1{,}000} \times 70\right)$ .... =

Thus proving that under these conditions as to increased cu[illegible] with increase of age or decreased efficiency, it is cheapest [illegible] the lamps for fully 1,200 hours' lighting.

America the lamps cost only about 2s. each, and the power cost of a cent for 50 watt-hours, or 8d. per "bot," hence it would be n that there it was more economical to throw away the lamps in uch shorter time than in their case. Also, when the public were pplied from a central station in this country at 8d. per "bot," would be more economical to throw away their 16 c.p. lamps in s than 1,000 hours. With a *constant* voltage throughout the time amp was kept in place—say, 1,000 hours—the power required at end of the 1,000 hours' lighting was less than at the beginning, ce the resistance gradually increased, but the candle-power reased. They knew, however, that the candle-power given out a lamp near its normal voltage was very quickly increased by a all percentage increase in the potential difference at its ter-nals. Hence, it simply became a matter for experiment and culation to determine the most economical life and maximum e of voltage to be given to a set of lamps which were intro-ced at one time into a self contained installation. The case was refore different from that of a building supplied from a central tion, where the voltage had to be kept constant; and considering fact that steam was required daily throughout the whole year cooking purposes, and in winter for heating the building, they re confident that it was cheaper for the Athenæum to run its n installation than to obtain current from a central station at e present prices charged, or likely to be charged for some years come.

Mr. Mavor objected to the arrangement of having four medium-ed dynamos instead of two large ones. This arose, in the first stance, from the Athenæum possessing two of the present namos in their old installation, and it was found cheaper to nvert them so as to suit the reduced speed and other require-ents of the new installation than to purchase new ones. Further, gave four strings to the bow instead of two. Any ordinary ddler could play a uniform tune on four strings, but it took a illed one to play even an irregular tune on two strings. Mr. avor suggested the use of a spare armature, but where would he in the case of a short-circuit in the field magnet coils? They had asons to be satisfied with the present arrangement, and if they d the plant to order over again, they would adhere to the same an, for it gave greater flexibility in the management and for pairs.

Messrs. Couper and Sayers objected to the placing of the dynamos d switchboard in the same room with the boilers, but here again ey contended that the plant was more easily attended to, and yet they had not found that anything had been hurt or injured ereby, except Mr. Sayers's fingers. The reasons he gave for the itch being hot were not correct, for it was due to a dirty contact rom the effect of the breaking sparks on switching out the circuit) ot having been properly cleaned.

He was sorry that he had not had time to check all Mr. M'Whirter's calculations in regard to the dynamos, but he had vited him to come and see them at work, and to observe how ool they were after a lengthened run. His formula must have been armed up by an undue constant before application to the present se. Even assuming that the formula used by Mr. M'Whirter is orrect, he had overstated the power lost in watts in the field agnet coils. For, referring to the characteristic curves which he btained from No. 2 dynamo, it would be seen that at the maximum utput for which the dynamo was made, it gave 140 amperes and 13 volts at 500 revolutions, with 4·5 ohms added to the shunt oils, which were 26·8 ohms resistance. Hence 26·8 + 4·5 = 1·3 ohms total resistance in the shunt circuit. And 31·3 ohms ÷ 13 volts ÷ 31·3 ohms = 3·61 amperes in the shunt coils. The ower lost per second *in shunt coils* alone was therefore C^2R = ·61² × 26·8 = 350 watts. Add to this the power lost in the main eld magnet coils—viz., 140² A × ·023 ω = 450 watts—and they got a otal of 800 watts, instead of 1,017 watts, as stated by Mr. M'Whirter. he maximum rise in temperature $= \frac{W \times 55}{S} = \frac{800 \times 55}{840} =$ 52deg. C., nstead of 67deg., as stated by Mr. M'Whirter. But they did not equire to run the dynamos at this maximum output, since they had our of them at their disposal, of which any two were capable of over-aking the whole of the lighting required at any one time in the thenæum. In charging the cells the maximum rise in tempera-ure of the shunt coils did not come to within 20deg. C. of what Mr. M'Whirter made it out to be. Here, however, he would admit that hey had to be careful not to overheat the coils, since the current lowing through them was as much as they would comfortably with-tand. The dynamos they had got in the Athenæum were very good achines, and Mr. M'Whirter's whole criticism amounted to this, hat they should have been rated for a maximum of about 110 mperes instead of 140 amperes.

Mr. Sayers would have liked to have heard something about the ifferent systems of wiring buildings, but to have gone into every ide issue such as that would have unduly lengthened the paper. hey had arranged the fuses as follows. Both the positive and the egative mains from each dynamo had been protected by a cut-ut. Each of the branch mains to the different floors were provided ith cut-outs at their positive and negative sides, at their very unction to the dynamo mains. Each subsidiary branch was pro-ected on the positive side by a cut-out at the switch, which was lose to the branch mains. Finally, each lamp was protected on the egative side by a fuse. This complied with the best fire risk rules, nd was all that any fire insurance inspector up to his duty could or hould demand. The discrepancy which Mr. Sayers had pointed ut in regard to the existing engines and the illustrations was xplained by the fact that the makers were about to supply the thenæum with their latest make and design of Westinghouse ompound engines, from which he expected even still better results han those recorded in the paper from the trials of the present nes. He should be glad to record the results of the work done by these new engines (with the makers' approval) after they had been fitted, which would be early in September next. At the end of the 12 months' run with the plant, they would be better able to place a record of the working expenses before this institution. It was only by carefully recording such facts over a lengthened period that true deductions could be arrived at in such a new industry as that of electric lighting.

Finally, he had to thank Messrs. Whitelaw, Eadie, Christie, Uren, Robertson, Watson, and M'Leod, electrical engineering students attending his day laboratory classes, for their kind assistance with the tests, drawings, and calculations for his paper.

Note received from Mr. M'Whirter, 25th May, 1891.

Prof. Jamieson has taken exception to Esson's formula, and called my attention to it. I have had an experiment carried out upon a dynamo in the works with the view to determine how far the formula agrees with results as found in practice. A current was sent through the coil wound upon a dynamo for three hours, the temperature being measured at regular intervals on the outside of the coil, and at the end of this trial—*i.e.*, when the coil had reached a temperature where the radiation was equal to the gain, and there was no further increase in temperature—it was found that the temperature measured on the outside of the coil was then equal to over 70 per cent. of the ultimate temperature as found by the equation given by Esson.

PHYSICAL SOCIETY.—June 26.

Prof. W. E. Ayrton, F.R.S., President, in the chair.

Mr. J. Enright, B.Sc., was elected a member of the society.

The following communications were read:

"**The Construction of Non-inductive Resistances,**" by **Prof. W. E. Ayrton, F.R.S.**, and **Mr. T. Mather**. In making some transformer tests about three years ago the authors had occasion to consider the construction of electric conductors, the impedances of which should be practically equal to their resistances. This condition could only be fulfilled by making the inductance small in comparison with the resistance, and as the former does not depend on the material employed (excepting iron) it was important to use substances of high specific resistance. Carbon or platinoid being available, the latter was chosen on account of its low temperature coefficient. One form of resistance exhibited consisted of strips of thin sheet platinoid, about 6 metres long and 4 cm. wide. Each was bent at the middle and doubled back on itself, thin silk being placed between the contiguous parts, and narrow ribbon used to bind the parts together. Twelve such strips arranged in series had a resistance of 2·95 ohms, and would carry a current of 15 amperes without changing its resistance more than $\frac{1}{10}$ per cent. This strip resistance was made by Messrs. C. A. Lamb and E. W. Smith, who at that time (1888) were students in the Central Institution, and to whom the authors' best thanks are due for the praiseworthy manner in which they surmounted the difficulties which presented themselves. Another form of resistance designed for portability consisted of bare wire spirals, each length having a left-handed spiral placed within a right-handed one of slightly larger diameter, and the two being connected in parallel. This device was found to reduce the inductance to $\frac{1}{10}$ or $\frac{1}{20}$ of that of a single spiral, according as the diameters of the spirals approach towards equality. When the spirals are made of platinoid wire the ratio of inductance to resistance is very small, averaging about $\frac{1}{500000}$.

"**On the Influence of Surface Loading on the Flexure of Beams,**" by **Prof. C. A. Carus-Wilson**. Referring to the practical treatment of problems on beam flexure, as based on Bernoulli's hypothesis that the bending moment is proportional to the curvature, the author pointed out that this assumes that the cross-sections remain plane after flexure and neglects the surface loading effect. The present paper describes experiments made to determine the actual state of strain in a beam doubly supported and carrying a single load at the centre, the effect of surface loading being taken into account. The method of investigation assumes that: 1. The true state of strain at the centre of a beam may be found by superposing on the state of strain due to bending only, that due to surface loading without bending. 2. The state of strain due to surface loading only may be found with close approximation to truth by resting the beam on a flat plane instead of on two supports. 3. The strain due to bending alone may be obtained from the Bernoulli-Saint-Venant results. Before proceeding to describe the experiments, a short account of the mathematical work previously done on the subject was given. The nearest approach to the particular case here dealt with had been worked out by Prof. Bouissinesq, who had shown that for an infinite elastic solid bounded on one side by a plane surface and loaded along a line on that surface, the stress, y, on an element on the normal through the middle point of the line varies inversely as its distance, x, from the surface. The formula thus arrived at was $y = 0·64\,\frac{P}{x}$, whilst for a finite beam, centrally loaded, the author's experiments gave $y = 0·728\,\frac{P}{x}$. The experiments were made on glass beams mounted in a steel straining frame, and placed between the crossed Nicols of a polariscope. Steel rollers, 2 mm. in diameter, served

as supports, and the central load was applied by a screw acting on a roller of similar diameter. Deflections of the beam were measured by a micrometer screw at a point opposite the central load, and traversing screws enabled the whole frame to be moved, so as to bring any portion of the beam in the field of view. Circularly polarised light was sometimes used, and a micrometer eye-piece served to measure the distances between interference fringes produced by loading. By carefully chosen experiments the author had shown that if a beam of glass be laid on a flat surface, and loaded across its upper surface, the shear at any point on the normal at the point of contact of the load is inversely proportional to the distance from the point of contact. In the first experiment the crossed Nicols were set at 45deg. to the axis of the loaded bar. A quarter-wave plate was then placed between the bar and the analyser, and the position of the black spot at the point where the effect of the shear on the polarised light was equal and opposite to that produced by the quarter-wave plate was noted. A second quarter-wave plate was then superposed on the first. The black spot moved upwards to a point where the shear was double that at the first position. This position having been determined, one quarter-wave plate was removed, and the load diminished, until the original spot moved up to the second position, and the processes were repeated. By this means a series of positions at which the shears were in the proportions, 1, 2, 4, 8, etc., were determined. Plotting the results showed the curve connecting the shear and the distance from the point of contact to be hyperbolic. Other experiments showed that the shear at any point was proportional to the load. By maintaining a constant load, and measuring the distances between the interference fringes below the point of contact, the hyperbolic law was confirmed. The effect of bending a beam is, according to hypothesis, to put the upper portion in longitudinal compression, and the shear (vertical stretch) varies as the distance from the centre of the beam. The shear due to surface loading is a vertical squeeze, and, as shown above, varies hyperbolically. When, therefore, the beam is subjected to both actions, the straight line representing the bending strain may intersect the hyperbola representing the shear due to surface loading in two points, and since at the corresponding points in the central section the shears are equal and opposite, the elements are only subjected to voluminal compression, and will exert no birefringent action. Hence, when viewed through crossed Nicols, black spots will be seen on a white field. Keeping the load constant and varying the span should cause the spots to approach each other, and when the line is tangential to the hyperbola the spots coincide. These deductions were confirmed by experiment, and it was found that for a span of less than four depths no point of zero shear exists on the central section. The strains in beams subjected to surface loading were thus shown to be of a character different from those usually assumed; the neutral axis, instead of coinciding with the axis of the beam, being lifted up in the centre, and its shape depending on the load and span. Other ingenious and interesting experiments on beams were described, in some of which the lines of principal stress were snapped out. Remarkable results were obtained, showing that although the tension lines given by Rankine and Airy are nearly correct, the curves of compression may be very different, and have very curious shapes. **Prof. Perry** thought the local loading effect would not be so important in long beams, and enquired whether, in ordinary test pieces, local loading would affect the breaking strength? He also asked what effect the fact of the load making contact over a surface, instead of along a line, would have on the results, and in reply, **Prof. Carus-Wilson** said the effect was to raise the asymptote of the hyperbola representing the surface loading stress, above the surface of the beam.

"**On Pocket Electrometers,**" by **C. V. Boys, F.R.S.** This communication described modifications of electrometers adapted for portability. As quartz fibres increase the delicacy and diminish the disturbing influences affecting instruments, much smaller controlling forces can be employed than when silk is used for suspensions. He had, he said, pointed out some time ago the great advantages arising from making galvanometers small. Applying similar reasoning to electrometers, he remarked that making an instrument one-tenth the size of an existing one reduced the moment of inertia of the needle to $\frac{1}{10^5}$, whilst the deflecting couple for given potentials would only be $\frac{1}{10}$ of its former value. The small instrument would for the same periodic time be 10,000 times more sensitive than the large one, provided the disturbing influences could be reduced in the same proportion. This, however, was not ordinarily possible, for any method of making contact with the needle, such as by a fine wire dipping into acid or mercury, prevented very small controlling forces being used. Still, by suitable devices, a large proportion of the full advantage could be obtained; a freely suspended needle without no liquid contacts was essential to success. The first instrument described was one in which the needle was cylindrical, contiguous quarters being insulated and connected to the opposite ends of a minute dry pile placed within the needle; opposite quarters were thus at the same potential, and at a different potential to the other pair of quarter cylinders. This was suspended within a glass tube silvered on the inside and divided into four parts by five longitudinal lines. In such an instrument the needle and quadrants
are reciprocal, and the deflection depends on ... roduct of the
difference of potential between the quadran... between
the parts of the needle. Owing to the dry p... onstant,
the instrument was found unreliable; but whe... best,
a Grove cell would ... mm. or 40 mm. ... next
step was to make ... needle of zi... nd
rely on contact ... on the par...
different potent... periment

successful, for the instrument was very sensitive. A disc
needle with quadrants alternately zinc and platinum w
employed, and by this a small fraction of a volt c
measured. The weight of the disc was only $\frac{1}{50}$th of a g
and the instrument could be turned upside down or
about in the pocket with impunity. Another small inst
with the stationary quadrants of zinc and copper was ex
and by rotating them through an angle of 90deg., s
bring them in a different position relative to the parts
needle, a deflection of several degrees of arc was pr
In the course of his remarks Mr. Boys made several sugg
relating to ballistic electrometers and electrostatic S
dynamometers, and pointed out the possibility of instrumen
as he had exhibited being of use in elucidating the obscur
in connection with so-called "contact electricity." The Pr
complimented Mr. Boys on the beautifully simple and rema
sensitive electrometers exhibited. He remembered that som
ago Mr. Gordon made a very small electrometer, but its in
was insufficient for electrostatic work. He agreed with M
as to the advantages of small instruments, providing s
across or tilting of the needle could be prevented. On th
hand, he thought the use of small potential differences on the
was a step in the wrong direction when great sensibili
required. **Prof. Perry** asked if the needle could not
charged by occasional contacts with a charged acid cup. M
said he had originally intended using a fairly highly charged
but had not yet done so. He also suggested that an elec
of very small capacity might be made by reducing the qu
surrounding a disc needle until they became like small tunin

A paper on "Electrification due to the Contact of Ga
Liquids," by Mr. J. Enright, B.Sc., and one on "The Ex
of Chlorine by Heat," by Dr. Arthur Richardson, were t
read.

The following correction should be made in the repor
meeting on June 12th: For the first sentence in Mr. Bla
remarks on Dr. Lodge's experiments, substitute "Mr. B
asked whether the pitch of the resonant jars altered wi
distance between the circuits was varied, for according to
the mutual induction should diminish the self-induction an
the oscillations to be more rapid."

COMPANIES' MEETINGS.

NATIONAL TELEPHONE COMPANY.

The eleventh ordinary general meeting of this Compa
held at Cannon-street Hotel on Thursday, Mr. F. R.
(president) in the chair.

The report, which was published in our last issue, havi
taken as read,

The **President** said that the net revenue account,
standing the heavy reductions made in their rates in the pr
still left them with an increased balance over last year, s
to pay the same rate of dividend on a much larger
They had carried the same amount to reserve as la
and although they carried forward a little less, t
accounted for by an item in the revenue account o
estimated dividends from subsidiary companies whi
not been received. In reference to the expense of the
debenture stock, the Directors decided, in view of t
of the money market, that it would not be a wise
take the risk of placing the whole amount, but that it
wiser to underwrite a portion, and the cost of doing t
shown in the account, £8,053. The Company's business
on increasing since the 30th April, the date to which the
were made up. The gross revenue at that date stood at
and on the 30th June it had increased to £424,899. The n
subscribers had also increased from 35,440 on the 30th April
on the 30th June. So that in spite of reductions in ra
had more than made up the loss in their annual revenue
course, they had a great deal more work to do; more
keep in order; more operators to pay; and more ca
which to pay dividends, so that the problem still was,
would this increase go on? He hoped, and thought the
all pointed that way, that when he met them next y
increase would have gone on to such an extent as to pro
all extra expenses, and make their net revenue and profi
good as it was then. They must not forget that thi
accounts had only felt the loss of January, February, Ma
April—the remaining eight months would fall on ne
The point was whether the progressive increase would be
to make up for that loss. It was perfectly clear the gross
would do so; the question was would the net result do so
improving the Company's system by changing the shack
insulators, and substituting magneto for ordinary batte
that work had been gone on with, and they had done a thi
as they had also of the rearrangement of the wires. Progre
would understand, in this work must be small, as it h
carried out while the ordinary service was going on; an
was another disadvantage, that with all the care they to
could not avoid contact between wires. That, of course,
on them complaints from subscribers. In all his compa
revenue he had left out the South of England Company,
it was not included for the whole year. As to the re-ele
the ...s (*vide* report) they had been very glad to t
op... in fact, thought it their duty to do so—of
th... he hands of the shareholders. They did so

sciousness of having done all they could in carrying on a very ricate and responsible business. He would be glad to answer questions.

Ir. **Harris** found fault with the Company's service, but declined pportion the blame, and other gentlemen asked questions as to accounts, Directors' fees, and so on, which were duly answered he **President**, who assured Mr. Harris that he would be only glad to personally attend to any complaints if they were de direct to him.

'he **President** then moved that the report and accounts be pted, and the dividend (*vide* report) be declared, which was onded by **Mr. J. Staats Forbes**, and carried unanimously.

ubsequently the President vacated the chair, and was duly lected with many flattering allusions to his ability and energy, also were the vice-presidents, Mr. J. S. Forbes and Colonel kson, and the whole of the Directors, the names being put *atim.*

'he **President** said that he proposed to fill up one of the two vincial vacancies on their Board by the election of Mr. William xander Smith.

'his was seconded by **Colonel Jackson** and carried unanimously. 'he auditors, Messrs. Welton, Jones, and Co., were then re-cted, and the proceedings closed.

NDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY.

A half-yearly meeting of this Company was held at Cannon-eet Hotel on Thursday, when the sanction of the shareholders s obtained to the payment of an interim dividend of 5 per cent., 10s. per share, free of income tax.

COMPANIES' REPORTS.

CHILI TELEPHONE COMPANY.

The report of the Directors to March 31, 1891, states that the tion in the Chilian Court between the vendor American company d a small minority of its shareholders was ready for decision, ion, by order of the Government, the courts were all closed, and ey have not since been reopened ; as, consequently, the impedi-ent to registration of the Company's title has not yet been moved, the business of the Company is continued in the name of e vendor company, but without serious damage to this Com-ny's interests. After the outbreak of the civil war the business the Company was stopped by order of the Government, which s since had the entire use of those of the Company's lines situ-ed within the districts remaining under its control ; but business s been resumed for the public at Iquique and other stations in stricts held by the Congress party. On March 31, when e present account ended, the public service at Santiago had en suspended for one month and 18 days. For the loss of business e Government will compensate the Company, and 62,000dols. d, on March 31, been received on account of such compensation. he Company's property has sustained damage only in the province Tarapaca. After all deductions are made the balance available r dividend is equal to 7 per cent. per annum upon the paid-up pital, as against a distribution of 5 per cent. for the previous ear. In view, however, of the continuation of the civil war—ith very indefinite prospects of its ending—and also in view of he fact that, for capital purposes, it has been necessary to use, tem-orarily, the income of the Company until the capital exchequer e replenished by further issue of securities—which cannot be one on satisfactory terms at the present time—the Directors ecommend that no dividend be paid, carrying forward, undivided, he whole balance of £14,210 until peace is re-established.

NEW COMPANIES REGISTERED.

City of Waterford Electric Supply Company, Limited.—Registered by H. F. Kite, 11, Queen Victoria-street, E.C., with a capital of £1,000 in £5 shares. The object of this Company is sufficiently indicated by the title. Registered without articles of association.

County of London Electric Lighting Company, Limited.—Registered by Sydney Morse, 4, Fenchurch-avenue, E.C., with a capital of £100,000 in £5 shares. Object: to carry on the business of electricians and electrical engineers in all its branches. The first subscribers are:

	Shares.
J. A. Kelman, 251, Winchester House, E.C.	1
J. C. Bull, 1 and 2, Great Winchester-street, E.C.	1
E. Garcke, 112, Belvedere-road, Lambeth, S.E.	1
B. H. Van Tromp, 4, Hyde Park terrace, W.	1
B. Broadhurst, 112, Belvedere-road	1
G. Parker, 20, Bucklersbury	1
T. Cooke, Winchester House	1

There shall not be less than three nor more than seven Directors; the first are the signatories to the memorandum of association. Qualification, one share. Remuneration to be determined in general meeting.

Hampstead Electric Light and Power Supply, Limited.—Registered by R. M'A. Inglis, 5, Victoria-street, S.W., with a capital of £1,000 in £1 shares. The objects of this Company are sufficiently indicated by the title. With slight modifications, the regulations contained in Table A apply.

International Inventions Corporation, Limited.—Registered by P. J. Rawlings, Avenue road, New Southgate, N., with a capital of £100,000 in £1 shares. Object: to carry on business as bankers and capitalists, and also as civil, mechanical, and electrical engineers, etc. **The first subscribers are:**

	Shares.
W. T. Prestoe, 32, Woodstock-road, Hornsey, N.	1
P. J. Rawlings, Avenue road, New Southgate, N.	1
T. Baker, 6, Mount Pleasant road, Lewisham, S.E.	1
E. T. Clarke, 51, Milkwood-road, Herne-hill, S.E.	1
H. A. Pinchbeck, 71, Queen-street, E.C.	1
W. E. C. Pinchbeck, 71, Queen-street, E.C.	1
J. Chinn, 1, Oakden-street, Kennington-road, S.E.	1

There shall not be less than three nor more than nine Directors The first shall be the first signatories to the memorandum of association. Qualification, 50 ordinary shares. Remuneration, Chairman, £250 per annum; ordinary Directors, £150 each per annum.

South American Cable Company, Limited.—Registered by Wilson, Bristows, and Carpmael, 1, Copthall buildings, E.C., with a capital of £500,000 in £10 shares. The objects of the Company are the establishing, maintaining and working of telegraphs, telegraphic, telephonic, or other communication, as well overland as submarine, from, in, and between South America, Africa, Europe, and islands or places in the Atlantic Ocean, or any of them. The first subscribers are:

	Shares.
A. Scott, 149, Leadenhall-street, E.C.	1
H. Marsham, 28, Bury-street, St. James's	1
J. W. Silver, Letcount Manor, Wantage	1
R. Henderson, 7, Mincing-lane	1
R. K. Gray, 106, Cannon-street, E.C.	1
M. Gray, Lessness Park, Abbey Wood, Kent	1
A. W. Jarvis, M.P., 120, Mount-street, W.	1

There shall not be less than three nor more than seven Directors; the first shall be appointed by the signatories to the memorandum of association. Qualification, £500. Remuneration, £1,200 per annum, with a further 5 per cent. on the surplus profits after 6 per cent. dividend, the same to be divisible.

St. John, Hampstead, Electric Supply Company, Limited.—Registered by H. F. Kite, 11, Queen Victoria-street, E.C., with a capital of £1,000 in £5 shares. The object of this Company is sufficiently indicated by the title. Registered without articles of association.

CITY NOTES.

The Telegraph Construction Company announces a dividend of 12s. per share.

Brazilian Submarine Telegraph Company.—The receipts for last week were £5,028.

City and South London Railway.—The receipts for the week ending July 4th were £710, against £697 for the week ending June 27th.

Eastern Extension Telegraph Company.—The receipts for June were £39,749, against £43,198 for the corresponding period of 1890.

Traffic Receipts.—The Eastern Telegraph Company's receipts for the month of June were £52,341, against £51,019 in the corresponding period of 1890.

Cuba Submarine Telegraph Company.—The estimated receipts for the month of June were £3,500, as compared with £3,324 in the corresponding month of last year.

Great Northern Telegraph Company.—The receipts for June were £27,400, making the total since January 1st £141,400, against £130,400 in the corresponding period of 1890, and £129,400 in 1889.

Western and Brazilian Telegraph Company.—The receipts for the week ended July 3, after deducting 17 per cent. of the gross receipts payable to the London Platino Company, were £3,563.

West Coast of America Telegraph Company.—The receipts for the month of March were £3,250, for April £600, for May £1,275, and for June £1,575. The southern cables are still interrupted, owing to the revolution in Chili.

West India and Panama Telegraph Company.—The estimated receipts for the half-month ended the 15th June are £2,491, as compared with £3,186 in the corresponding period of 1890; and for the half-month ended 30th June £2,264, compared with £3,242.

Wyndham Electric Light Company, Limited.—Registered by Drake, Driver, and Leaver, 13, New Bridge-street, E.C., with a capital of £1,500 in £1 shares. Object: the public and private lighting of the village of Blaenrhondda by electricity. Registered without articles of association.

Direct United States Cable Company.—The Directors have resolved to recommend a final dividend of 3s. 6d. per share, free of income tax; such dividend to be payable on and after the 24th inst., making, with the interim dividends already paid, 3½ per cent. for the year ending 30th June last, carrying forward a balance of £3,502. 1s.

St. James's and Pall Mall Company.—The receipts of the Company for current sold during the quarter ending June 30 amounted to £6,632, as against £1,991 in the corresponding

period of last year. The amount received for the quarter ending March 31 was £9,652, against £1,818 for the corresponding period of last year. The falling-off in last quarter's receipts as compared with those for the first quarter of the year is, of course, to be attributed to the longer hours of daylight, and the consequent decrease in the demand for artificial light.

Eastern Telegraph Company.—Subject to final audit, the accounts of the Company show, after placing about £95,000 to reserve fund, a balance available sufficient to pay at the general meeting on the 16th inst. the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the preference shares, less income tax ; and a final payment of 2s. 6d. with a bonus of 3s., both free of income tax, on the ordinary shares, making with previous payments a total distribution of 6½ per cent. on those shares for the year ended March 31 last. The Company's transfer-books will be closed until the 16th inst.

Edison-Swan Company.—The accounts of this Company for the year ending June 30, 1891, having been made up, the Directors have resolved, subject to audit, to recommend the shareholders to declare a dividend at the rate of 7 per cent. per annum for the six months ending June 30, 1891, making, with the interim dividend paid in February last, 7 per cent. for the year, and a further dividend of 10 per cent. in respect of the arrears of cumulative preferential dividend, to be distributed in accordance with the articles of association. The dividend will be paid upon the register as it stood on the 7th inst., and the dividend warrants will be issued on the 30th inst.

Companies of the Month.—The following companies were registered during June :

	Capital.
Albert Electric Lighting Company, Limited, £5 shares..	£10,000
Bournemouth and District Electric Supply Company, Limited, £5 shares	50,000
Babcock and Wilcox, Limited, £10 shares	240,000
County of London Electric Lighting Company, Limited, £5 shares	100,000
Electrolytic Caustic Soda and Chlorine Trust, Limited, £10 shares	10,000
Gloucester Electricity Supply Company, Limited, £1 shares	100
Hampstead Electric Light and Power Supply, Limited, £1 shares	1,000
International Inventions Corporation, Limited, £1 shares	100,000
Middlesbrough Electricity Supply Company, Limited, £1 shares	100
Ogmore Valley Electric Light and Power Supply Company, Limited, £5 shares	10,000
Queen Anne's-mansions Lighting and Heating Company, Limited, £10 shares	60,000
Rochdale Electricity Supply Company, Limited, £1 shares	100
Stoke-upon-Trent Electricity Supply Company, £1 shares	100

PROVISIONAL PATENTS, 1891.

JUNE 29.

11016. **Improvements in armatures of dynamo-electric machines and electric motors.** Hugh Longbourne Callendar, 2, Prince's-mansions, Victoria-street, London.

11048. **Improvements in the preparation and laying of electrical mains on the Brooks system.** Walter Claude Johnson and Samuel Edward Phillips, 28, Southampton-buildings, London.

JUNE 30.

11060. **Improvements in thermo-electric batteries.** Paul Giraud, 52, Chancery-lane, London.

11075. **Electric meters.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, London. (Herbert Morris Pilkington and Roger Sherman White, United States.)

11082. **An improved telephone combination.** Sir Charles Stewart Forbes, 21, Finsbury-pavement, London.

11093. **A simple device for detecting a leakage to earth, principally adapted to isolated electric light installations.** Wallace J. Saudy and William A. Easter, 41, Choumert-road, Peckham, London.

11108. **Improvements in and connected with electric primary batteries.** Theophilus Coad, 1, Quality-court, London.

11113. **Improvements relating to electromotors, and to the transformation and distribution of electric currents.** Friedrich Wilhelm Lahmeyer, 433, Strand, London.

11118. **Improvements in electrical signals for steam vessels and analogous purposes.** Alexander Melville Clark, 53, Chancery lane, London. (Edwin Warren Tucker and Leopold Katzenstein, United States.) (Complete specification.)

11120. **Improved leading-in wires or conductors for incandescent electric lamps and the like.** Reginald Aubrey Fessenden, 45, Southampton-buildings, London. (Date applied for under Patents Act 1883, Section 103, 18th February, 1891, being date of application in United States.)

11133. **Improvements relating to dynamo-electric machines and electric motors, and to apparatus connected therewith.** Henry Harris Lake, 45, Southampton-buildings, London. (The Crocker-Wheeler Electric Motor Company, *United States.) (Complete specification.)*

11134. **Improvements in apparatus for the electrolysis of aluminium.** Camille Alphonse Faure, 46, Lincoln's-inn-fields, London.

11144. **Improvements in printing telegraphs.** Henry Van Hoevenbergh, 47, Lincoln's-inn-fields, London.

11145. **Improvements in and connected with printing telegraph instruments.** David Homer Bates and Henry Van Hoevenbergh, 47, Lincoln's-inn-fields, London. (Complete specification.)

11149. **A multiple filament electric incandescent lamp.** Emile Guitton, 166, Fleet-street, London. (Ad. Collett, France.)

JULY 1.

11157. **Improvements in transmitters and receivers for telephones.** James Radcliffe and James Ernest Spagnoletti, 2, Great George-street, Westminster, London.

11181. **Improvements in electric switches.** Henry Alexander Mavor, William Arthur Coulson, Sam Mavor, and William Brooks Sayers, 62, St. Vincent-street, Glasgow.

11201. **Improvements in apparatus for telephonic communication.** Joseph Sack, Emil von Maltitz, and Peter Ziesel, 433, Strand, London. (Complete specification.)

11211. **Improvements in interrupters for strong electric currents.** Martin Kallman and The Company Allgemeine Elektricitats Gesellschaft, 47, Lincoln's-inn-fields, London.

JULY 2.

11225. **The improvement of production of electricity by means of a dry cell battery.** Francis Joseph Rehman, 40, Berners street, London.

11278. **Improvements in the production of elements for electric or secondary batteries.** Emmanuel Hancock and Augustus John Marquand, 24, Southampton-buildings, London.

JULY 3.

11294. **An improved system of telephonic exchange signalling.** Alfred Rosling Bennett, 22, St. Albans-road, Harlesden, London.

11301. **Improvements in or relating to driving electric current generators for lighting steamships and railway trains, and for other purposes, and in apparatus therefor.** Paul Raoul de Faucheux d'Humy, 6, Lord-street, Liverpool.

11313. **Improvements in means or apparatus for utilising electrical energy in operating rock boring and other mechanism.** Reginald Bolton, 55, Chancery-lane, London.

JULY 4.

11384. **An improved electric igniting device applicable for use in motor engines operated by the combustion of vapours or gaseous hydrocarbon.** William Dent Priestman and Samuel Priestman, 191, Fleet-street, London. (R. B. Elwell, Australia.)

11407. **An improved thermo-electric meter.** Frederick William Cannon, 166, Fleet-street, London.

NOTES.

Stock Exchange.—Telephonic communication is now open between the London and the Manchester Stock Exchange.

Price of Current.—At Saint-Brieuc the hecto watt-hour (100 watt-hour) is sold at ·7d. This is stated to be the lowest in France.

Bridlington.—New Local Board offices are to be built at Bridlington. It will probably mean a job for electrical engineers as well.

Translations.—The French Bibliothèque Nationale has opened a register of persons capable of translating scientific works into any tongue.

Electric Bus in Paris.—*Electricité* chronicles the appearance of a waggon drawn at considerable speed by electricity in the streets of Paris.

Overhead Wires.—At the London County Council mention was made that the London Overhead Wires Bill received Royal assent on 3rd inst.

Miners' Lamps.—The Renard chloro-chromic battery is being applied to miners' lamps, the weight being the same as the ordinary safety lamp.

Continental Electric Railways.—The Allgemeine Company of Berlin are to construct two electric tramway lines on the Sprague system at Stockholm and at Kiew.

Calcutta.—A new departure is to be made in street lighting at Calcutta. The Corporation are advertising for tenders for lighting the new Central-road with electricity.

Taunton Exhibition.—Field-Marshal Sir J. Lintorn Simmons has consented to open the electrical appliances and electric light exhibition to be held in Taunton shortly.

Accumulators for Sweden.—It is announced that the Swedish excise authorities have declared accumulators to be scientific instruments and allow them to enter duty free.

Electric Tricyles.—One of the most influential companies of Paris, says the *Bulletin de l'Electricité*, is experimenting with electric tricyles, and something further will probably soon be heard.

Chelsea.—The Vestry of Chelsea have presented a petition against the recommitment of the Electric Lighting Provisional Order Confirmation Bill, dealing with the parish of St. Luke, Chelsea.

Helston.—At a special meeting of the Town Council on Monday Mr. Veale, of St. Austell, gave details of the cost of lighting the town electrically. He is to give an estimate and confer with a committee on the matter.

Electrolytical Analysis.—The method of chemical analysis by electrolysis is spreading. A special installation of accumulators has been made, says the *Bulletin de l'Electricité*, for this purpose in the Ecole Normale Superieure of Paris.

Greenwich Observatory.—The Astronomer-Royal considers it desirable a complete installation of electric light should be adopted at the Royal Observatory. The lighting is now done by a number of Pitkin batteries and lamps.

City and Southwark Subway.—A long and interesting account of the English triumph in the electric subterranean railway to Stockwell has been given by the *Etoile Belge*, which is reproduced in *L'Ingenieur Conseil* for 12th July.

Telephones for Cardiff.—The Cardiff Town Council have resolved, on the motion of the chairman, that an estimate of the cost of establishing telephonic communication between the Bute Docks and the central police station be obtained.

Fribourg.—Water power is used at Fribourg for turbines driving dynamos direct for lighting and power. The current is distributed at the rate of ·1d. per horse-power hour over 20 h.p. ; ·12d. from 5 h.p. to 20 h.p. ; and ·15 for less than 5 h.p.

Richmond Town Hall.—Municipal buildings are to be erected at Richmond to designs by Mr. H. J. Ancell, architect, 3, Staple-inn, London. They should be wired ready for electric light. The tenders are to be sent in by August 4 to the town clerk, Richmond.

Paris.—The Creuzot Works have received the contract to install the electric light in the Gare d'Orleans at Paris. The Ganz system will be used. Sixty lamps of 25 to 40 carcels, and two of 250 carcels, are also being installed by another firm in the Gare Montparnasse.

Continental Telegraphs.—In the Lower House of the Austrian Diet, the Marquis von Bacquehem, Minister of Commerce, stated that there was a prospect of the establishment in the course of the year of a direct telegraph line connecting Vienna, Munich, Paris, and London.

Personal.—Mr. E. Manville, M.Inst.E.E., writing to us from Albany-buildings, 39, Victoria-street, Westminster, notifies us that he has severed his connection with manufacturing companies, and is now carrying on exclusively the profession of consulting electrical engineer at the above address.

"Journal."—The *Journal* of the Institution, part 94, has appeared, and contains Dr. Fleming's, Mr. Preece's, and Mr. Crompton's contributions to the science of electrical mains, with discussions thereon, with also classified list of articles on electrical subjects and abstracts from the foreign journals.

Glasgow.—As will be seen from their advertisement, the Glasgow Corporation are desirous of securing a competent electrical engineer. The situation is an important one, and the salary will commence at a minimum of £250 a year, the engineer's whole time and attention to be given.

Electrical Units.—At the ensuing British Association meeting at Cardiff, it is proposed to hold in Section A, if possible in conjunction with Section G, a discussion on "Units and their Nomenclature," having special regard to the new electrical and magnetic units now becoming necessary for practical purposes.

Society of Arts.—The council of the Society of Arts have been asked by the Government to undertake the duty of organising the British section at the Chicago Exhibition in 1893, and are to be constituted a Royal Commission for that purpose. The formal documents constituting the commission will be issued very shortly.

Obituary.—Dr. William Henry Stone, consulting physician to St. Thomas's Hospital, died last week at his residence, Geraldine-road, Wandsworth, in the 62nd year of his age. Dr. Stone was very well known in electrical circles from his attention to questions of electricity in physiological science, and especially to that of the electrical resistance of the human body.

Canterbury.—At the meeting of the Canterbury General Purposes Committee last week, the Mayor mentioned that the Dover Corporation intended inviting contracts from the different companies to take over the provisional order ; they would thus see which company

offered the best terms. He did not think they could do better than follow their example.

Technical Institute at New Cross.—The Goldsmiths' Company are instituting a new technical and recreative institute at New Cross. Many technical classes will be held. That for electrical science will be under Mr. W. Slingo, A.I.E.E., principal of the Telegraphists' Central School of Science, his assistant being Mr. A. Brooker. The fees will be 7s. 6d. a session.

Aylesbury.—Tenders are invited for lighting the several public lamps and clock tower within the district of the Aylesbury Local Board, for one year from August 1st. The conditions for lighting, and all other particulars in connection therewith, may be obtained on application to Mr. George Fell, clerk, Aylesbury, to whom tenders must be sent by 31st inst. Electricity is not specially mentioned.

Overhead Wires at Dulwich.—The Camberwell Vestry have been much exercised with reference to overhead fire alarm wires. The Vestry wished to have them underground, but the London County Council would not sanction the expense—£29 instead of £18. This raised a stormy discussion, and the committee recommended that the London County Council be informed that the Vestry required the wires to be laid underground.

Electric Ventilators for War Vessels.—We learn that Messrs. Shippey Bros., of London, have secured the contract for fitting the new war-ships now being built in France for the Chilian Government with their large-size standard electric blowers. The method of ventilation will be the same as that which has so successfully worked on the s.s. "Baltimore" and other vessels, illustrations of which were given in our issue of April 25, 1890.

Holbeach.—The Local Board of Holbeach have been considering the question of whether they should use oil or gas for lighting the streets. During the past two years, by means of oil, they have effected a saving of 25 to 30 per cent. The tender for lighting by means of oil was again accepted. A member of the Board declared that it was a disgrace to the town to adopt such a course, and he said they were laughed at by visitors. He evidently wanted electric light.

Carshalton.—At the meeting of the Carshalton Local Board last week the clerk reported that he had only received one tender for lighting—namely, Messrs. Defries and Co.—offering to light the parish for 60s. per lamp per annum. No tender had been received from the gas company. The matter was adjourned, Mr. Taylor saying he was in favour of the electric light, and Mr. Sheppy likewise remarked that he agreed—they ought to move with the times.

City and South London Railway.—The suit of the London County Council against the City and South London Railway for infringement of building limit was not allowed and their appeal failed, it being held that words in the special Act, "as may be required for the purpose," implied that the railway company were to be the judges of what they would require. The Court having found that a station was necessary, there was no authority for compelling the company to build their station on any particular spot.

Salford.—Tenders are required for lighting the Ladywell Sanatorium by an electric light installation, for the county borough of Salford. Applications for specifications, accompanied by a deposit of £1. 1s. (which will be returned upon receipt of a *bonâ fide* tender), to be made to Messrs. Maxwell and Tuke, or Messrs. E. and F. Hewitt, architects, Manchester. Tenders, endorsed "Electric Lighting," addressed to the Chairman of the General Health Committee, must be delivered to Mr. Samuel Brown, town clerk, Town Hall, Salford, by 11 a.m. on 30th inst.

Reigate.—There has been a dispute in Reigate about the terms asked by the Redhill Gas Company. The company declined £3. 3s. per lamp offered by the Council, and the committee advised the invitation of tenders for electric lighting. There had been, however, no time for this till the expiration of the gas contract, and the Council determined to agree to the gas company's terms. The cost of gas is £1,800 a year, and there will probably be a feeling in favour of the consideration of electric light next year.

Central London Railway Bill.—With reference to the Central London Railway Bill, which is now before a Select Committee of the House of Lords, it was recommended and resolved by the Hammersmith Vestry at their last meeting, that in view of the many advantages of speedy transit and communication which the proposed railway will confer upon the northern portion of Hammersmith, and also having regard to the protective clauses and amendments which the promoters inserted at the instance of the Vestry, that the Vestry present a petition to the House of Lords in favour of the Bill.

Mutual Telephone Company.—Four hundred and seventy subscribers are now in communication through the Mutual Exchange at Manchester, and 500 will be joined by July 22. By the end of August 700 will be speaking. On July 31 the replacing of the present temporary transmitters by loud-speaking carbon ones will be commenced, and finished in about 10 days. At June 30 the Mutual Company's Manchester system comprised 421 miles of wire used as metallic circuit, in use, 150 miles of the same spare, 11 miles of single wire, 90 standards, 14 poles, 81 cables, 134 junction-boxes, and attachments to 430 buildings.

Motors for the City.—It was reported at the meeting of the Commissioners of Sewers last week, that notices had been received from the Brush Electrical Engineering Company of their intention to apply in the next session of Parliament for a provisional order authorising them to supply electrical energy for any public or private purposes within the City of London, and from the Laing, Wharton, and Down Construction Syndicate, of their intention to apply in the next session of Parliament for a provisional order authorising the said syndicate to amend the City of London (East District) Electric Lighting Order, 1890. These were referred to the Streets Committee.

Edison Lamp Patents.—The case brought by the Edison Electric Light Company against the United States Electric Light Company (owned by the Westinghouse Company), for the infringement of one of the patents belonging to the plaintiffs was decided on Tuesday in New York. Judge Wallace, of the United States Circuit Court, gave judgment, sustaining Edison's patent on the incandescent electric lamp. He also gave orders for an injunction against the defendant company, and for a return giving an account of the profits for the past manufacture of such lamps. The patent was sustained by the English Courts, with the decisions of which Judge Wallace's judgment apparently agrees.

Cork.—At the meeting of the Cork Corporation last week, the town clerk said with reference to the notice of intended applications to the Board of Trade by the Cork Gas Consumers' Company for a provisional order under the Electric Lighting Acts, to authorise the company to supply electrical energy within the municipal borough, and to take all needful action in respect of same as indicated by said Acts, it was necessary for the Council to fix a special day to consider the question at a month's notice. He would himself bring up a report on the matter. Alderman Scott

proposed that the fixing of the date be left to the town clerk, and said the Corporation should not allow the lighting of the city to be taken out of their hands again. The proposition was agreed to.

City Lighting.—The Streets Committee of the Commissioners of Sewers have reported that a notice had been received from the Brush Electrical Engineering Company of their intention to lay a line of main conductors under the footway of both the north and south sides of Cannon-street, from Walbrook to and including the south side of St. Paul's-churchyard, and a line of main conductors from Queen Victoria-street, through Bucklersbury to the junction-box by the Mansion House, and the committee recommended that consent should be given, subject to the provisional order, and that the committee be empowered to give the necessary sanction, from time to time, for the different sections of the work of City electric lighting, subject to the contracts and provisional orders.

The World's Fair.—It is probable that the Chicago Exposition will be open in the evenings, in all its departments. Plans and estimates have been invited for lighting by electricity all of the buildings. It is proposed to light both the buildings and grounds so brilliantly that everything can be seen at night as well as by day, and it is expected that the scene at night will be one of marvellous brilliancy. United States Attorney-General Miller has rendered a decision that will be of great interest to foreign exhibitors. It is to the effect that these exhibitors can bring with them enough employés to show the process of manufacturing the goods they display without being held for violation of the contract labour law. The decision was rendered at the request of the French Consul in Chicago, who represented that many manufacturers in France would not take part in the fair unless they could bring with them a limited number of employés. The Chicago Exhibition authorities have already received 1,000 applications for space.

Athletic Sports.—Mr. Ronald A. Scott, M.I.E.E., M.R.I., etc., the well-known electrical engineer, evidently vies with his brother, Commander Percy Scott, R.N., in getting up athletic meetings, and notwithstanding the counter attractions of the Royal review and the Eton and Harrow match, nearly 500 visitors responded to the invitation on Saturday last, and evidently thoroughly enjoyed themselves in the grounds, some 20 acres in extent, which surround Mr. Scott's residence, "The Elms," Acton-hill, W., so well known to travellers along the Uxbridge-road. There were 16 events, all well carried out; but the final one, walking the greasy pole over the lake, was certainly exciting and caused roars of laughter, whilst it brought out some splendid exhibitions of swimming. At last, after many futile attempts and consequent duckings, General Rich's son made a rush for it and succeeded in picking off the flag during his somewhat comical descent into the water. All the competitors were members of the Acton-hill Electric Engineering Works.

City Electric Lighting Company.—The new company for taking over the contracts and concessions for the electric lighting of the City has been brought out this week, under the name of the City of London Electric Lighting Company, Limited, with a capital of £800,000 in 40,000 preference and 40,000 ordinary shares of £10 each, of which the ordinary shares are now issued. The directors are Sir David Salomons, Bart., chairman, Edward Lucas, Esq. (of Messrs. Lucas, Micholls, and Co.), F. W. Reynolds, Esq. (of Messrs. F. W. Reynolds and Co.), the Duke of Marlborough (chairman of the Electric and General Investment Company, and of the Brush Electrical Engineering Company), the Earl of Suffolk and Berkshire, Hon. Alan Charteris (Lloyds, E.C.), J. Bevan Braithwaite, jun., Esq. (director of the Electric and General Investment Company, and of the Brush Electrical Engineering Company). Chief engineer, Major-General C. E. Webber, C.B., past-president of the Institution of Electrical Engineers. Secretary, J. Cecil Bull, Esq. Offices, 1 and 2, Great Winchester-street, E.C.

The German Emperor's Palace.—It will not be without interest at this juncture to read the details of the electric installation at the Royal Palace at Berlin. Hitherto the illumination has been by candles, no gas having been admitted. The whole has recently been fitted with electric light. The plant consists of two engines, of 150 h.p. and 50 h.p. Space is arranged for two others of 200 h.p. each. There are two dynamos—a four-pole machine driven by the smaller engine, and a six pole machine of 100,000 watts, coupled to the 150-h.p. engine. When finished, the total present capacity will be 360,000 watts, with a battery of 860 ampere-hours capacity. In the Imperial chambers there are 557 lamps of 10 c.p. to 25 c.p. The corridors contain 152 incandescent lamps, and offices 133 lamps. The gateways have nine arc lamps of six amperes. The ball-rooms and drawing-rooms have in all 1,960 incandescent lamps, of which over 1,000 are in the great White-room. A number of motors are also used. It is expected that two other Siemens dynamos will be installed with a further battery of 800 ampere-hours.

Telephone Clauses in the Electric Lighting Acts.—At a recent meeting of the Electric Trade Section of the London Chamber of Commerce, the secretary of the Chamber stated that they had approached the Board of Trade on the question of telephone clauses in the Electric Lighting Acts, but the reply was considered so unsatisfactory that the idea of sending an influential deputation was abandoned. We learn now, that although it was not communicated to the secretary of the Chamber, that the Board of Trade had evidently thought better of it, and subsequently altered the provisional orders by inserting those clauses for the protection of the telephone company desired by the Chamber of Commerce, in lieu of those previously inserted in the orders. It is believed that the action of the Chamber has in no small degree contributed to the satisfactory result, and we would hope that the same body may now be able to achieve an equally satisfactory result in regard to the "overhead wires" question; action in regard to which we believe was only delayed in consequence of the unsatisfactory reply already referred to.

Tenders for Bradford Town Hall.—The Finance Committee of the Bradford Town Council have recommended that the Council should accept the tender of Mr. Wilson Hartnell for the providing and fixing of fittings required in the lighting by electricity of rooms in the municipal buildings, for the sum of £630. Mr. James Pratt asked why it was that the committee had not advertised for tenders, and why, if they thought it expedient to advertise, they had not seen their way to let the contract to a Bradford firm. Mr. S. Robinson suggested that the question should be allowed to remain over. Alderman F. Priestman said that he believed the course taken by the committee was to select six or eight firms who were thought suitable, and invite them to tender for the work to be done. The tenders in the present instance were in the room, and the committee, after going carefully over the matter, accepted the lowest one. Mr. Oddy accepted the suggestion made by Mr. Robinson as to allowing the resolution in reference to the electric lighting of the Town Hall to stand over for the present. This part of the resolution was therefore withdrawn.

British Association at Cardiff.—Another meeting of the Cardiff Committee of the British Association was held on Monday night in the Town Hall. Mr. T. Webber presided over an attendance which comprised Messrs. S. Jones, C. Jones, W. H. Allen, and Mr. R. W. A. Atkinson and Prof. Tanner (joint hon. secretaries), and Mr. S. W. Arnold (assistant secretary). Prof. Tanner reported with reference to the proposed lecture for working-men to be delivered during the British Association week, that a lecture to working-men had been given every year since 1867, except on two occasions. It would depend upon the extent of support given by working-men of the town and district as to whether the lecture would be delivered. If any surplus remained, it would go to a local charity. Prof. Silvanus Thompson had been invited to be the lecturer, and the subject he had chosen was "Electricity in Mining," a subject of considerable interest, and one which ought to draw a lot of people from the valleys. Dr. Thompson would show many experiments. On the motion of Mr. Jones, seconded by Mr. Allen, it was resolved to make arrangements for the lecture being delivered in Wood-street Chapel on August 22. It was decided to enlist the support of both employers and employed in connection with the matter.

Oyonnax.—The Compagnie Lyonnaise d'Electricité ordered of MM. Cuenod, Sautter, et Cie., of Geneva, the plant for an important installation for transmission of power to Oyonnax (Ain), of which the following particulars are given: The motive power is furnished by a fall of the Oigrim, a tributary of the Ain, of 60ft. head, and yielding a possible force of 1,750 h.p. The generating station consists of two groups, each comprising a horizontal turbine coupled direct to a Thury dynamo of 150 h.p., giving at 350 revolutions 105,000 watts at 2,000 volts; these two dynamos are coupled in series. The line is five miles long: it is formed of three wires, two of 6·5 mm. and the other of 4·5 mm. diameter; the loss along the line is reckoned at 10 per cent. Two motors of 120 h.p. coupled in series receive current at 1,800 volts; these drive direct two secondary dynamos, giving 600 amperes at 125 volts. This current is to be used for the distribution of light and power in the town of Oyonnax by means of a three-wire distribution. The tests made have shown a total efficiency of 76·2 per cent. The installation has been in regular work since March, 1890, and has not ceased to run with the greatest regularity ever since, in spite of the extreme cold of the late winter, which stopped without exception all the hydraulic installations in the neighbourhood.

Electric Tramways for Walsall.—The General Purposes Committee of the Walsall Town Council on Monday reported that they had considered the report of Mr. F. Brown, of the Walsall Electrical Company, upon his recent enquiries in America as to the working of tramway lines there with electric motors to be supplied with electricity by means of overhead wires. They recommended that, subject to arrangements being made by the company to the satisfaction of the committee as to the terms and conditions upon which poles shall be placed in the public streets, and overhead wires shall be carried along and across such streets, and cars run on the tramways by electricity, the consent of the Council be given to the company working these lines by means of overhead wires, and that the committee be authorised to employ an electrician to advise them as to the conditions and terms to be imposed upon the company. Alderman Evans proposed the adoption of the recommendation, and stated that Mr. Brown was completely satisfied with what he saw in America, and the fact that town after town, to the extent of hundreds, had adopted the system. Mr. Powell seconded the proposition, giving particulars of the proposed arrangements. Dr. Stead was fearful that there would be great danger to life and limb from the introduction. Alderman Holden objected to Walsall being the first place in the kingdom to try the experiment. The chairman and others supported the motion, which was finally carried by 15 to 5.

Catalogue.—Messrs. Ernest Scott and Mountain have forwarded to us a copy of their catalogue of electrical apparatus for electric light, electroplating, and transmission of power—a neat book of 144 pages, containing many illustrations and a vast amount of special and incidental information, with a complete index. The book deals first of all with the advantages of electric light, and gives specimen installations and their approximate cost. The Tyne dynamo is illustrated and fully described, with special stress laid upon such matters as are likely to arise in erecting and running the plant. Tables are given showing the hours of necessary lighting throughout a year of 8,760 hours—sundown to various hours up to midnight, or 2 a.m. or 4 a.m., etc. The question of alternating dynamos and transformers is given a separate chapter. Arc lamps of various kinds are dealt with, and tables of prices, carbons, and candle-power are given. Projectors, Admiralty switches, cut-outs, and all other necessary apparatus are described, special attention having been given to ship fittings. Wiring tables through various qualities of insulation show insulation resistance, size and prices, and very careful instructions are given for jointing cables. Accumulators are also dealt with in a similar way, with complete instructions for their management. Telephones, steam and gas engines, and turbines are also illustrated. Altogether this catalogue makes an interesting and useful work of reference to electrical contractors and authorities.

Chislehurst.—At a meeting of the Chislehurst local authority, on Monday, the deputy clerk read a letter from the Provincial Electric Lighting Power Supply Company, Limited, of 5, Queen Victoria-street, notifying their intention of applying for a provisional order for supplying electricity in the parish of Chislehurst. The clerk stated he understood that Mr. Willet, the owner of the Camden Park Estate, was interested in the company, whose action was taken in consequence of the development of the estate. Mr. Willet proposed that there should be no gas used in the houses to be built on his land, but that each house should be supplied with electricity supplied from a central station. The serious part of the matter was that if the company obtained the provisional order, they would shut out the authority from supplying electricity. The authority, however, could pursue the same plan as had been followed by the Bromley Local Board, who took out the order themselves. Mr. Clarence Smith said that what they had to do was to prevent the company from getting an order and not carrying it out. If this was a respectable company with plenty of capital, there was no need to oppose the application so long as the promoters were willing to supply the neighbouring property. The clerk said cases had been known in which companies without capital or reserves had obtained such rights of very large districts merely for the purpose of retailing them to others. On the motion of Mr. Clarence Smith, seconded by Mr. Charrington, it was resolved to make enquiries into the status of the applicants.

Hanley.—At the meeting of the Hanley Town Council last week the General Purposes Committee recommended that, in consideration of his extra services rendered in connection with the erection of the Victoria Hall and Quarter Sessions Court and the alterations to the Town Hall, the borough surveyor (Mr. J. Lobley) be allowed two months'

leave of absence, and that he be granted the sum of £100. In moving that the recommendation be confirmed, Alderman Bromley said that Mr. Lobley had undertaken a great deal of work for the Corporation outside the strict duties of his office, and had thus saved the town a considerable sum in extras and architects' fees. He had well earned the gratuity of £100 which it was proposed to give him. Mr. Shirley seconded the motion, mentioning that Mr. Lobley proposed visiting America during his holiday, mainly with the object of enquiring into the question of lighting towns in that country by electricity. Alderman Charlesworth, in supporting the motion, said the borough was to be congratulated upon having in Mr. Lobley not only an efficient borough engineer, but a man of architectural skill. His extra services as an architect, not only in connection with the Town Hall, Victoria Hall, and Sessions Court, but at the Shambles and other Corporation property, had saved the town, it was estimated, at least £500 or £600. An amendment to the effect that the leave of absence be granted, but not the gratuity, having been proposed, the Mayor pointed out that the Corporation were committed to the expenditure within the next few years of £30,000 or £40,000 in electric lighting, and upon that question they required the fullest information. In America electricity for public lighting was more largely used than in this country, and as the surveyor was going to enquire into the subject during his holiday, he thought the Council would get their money's worth back again in the information and assistance he would be able to afford them. After a long discussion, the amendment was rejected, and the recommendation of the committee was then confirmed.

Withdrawal of the Birmingham Tramways Order.—The Central Tramways Company have, it is understood, abandoned the provisional order they were promoting in Parliament to authorise the extension of the electric tram line in Birmingham. This action has been forced upon the company by the opposition of the telephone company, which obtained from the Lords' Committee a clause requiring the tramway company to protect the underground telephones by making provision for return currents wherever electric tramway cables may be laid. The cost of such an arrangement, according to the tramway company's witnesses, would amount to £1,500 per mile, and the total cost, supposing electricity to be adopted throughout the tramway system, is estimated at £20,000. The directors felt that they could not ask their shareholders to submit to a requirement, in their judgment, so excessive and unjust, and therefore, rather than accept the clause, they have withdrawn their order. The immediate effect of the telephone company's opposition is that the Bristol-road electric trams must still stop in Suffolk-street to the great inconvenience of passengers, although the Navigation-street lines are laid and were used for a time, until it was found necessary to obtain further powers to legalise their use. The further and more serious effect is that the development of the electric system of traction is rendered impossible, because the cost of laying underground wires (the only method that will pay) is rendered too heavy through the demand of the telephone company. The application of the tram way company, it will be remembered, was strongly supported by the Corporation, and they resisted the claim of the telephone company. The success of the latter company, and the consequent necessary withdrawal of the tramway company's order, compels Birmingham to submit for an indefinite period to the nuisance of steam trams, which would otherwise have been replaced by electric trams. This result is greatly to be regretted. It is hoped that on a future application, made before another Parliamentary Committee, the tramway company may be successful in obtaining its order without the intrusion of the obnoxious clause.

Bradford Central Station.—Before the Bradford Town Council, on Tuesday, Alderman F. Priestman stated with regard to the electric lighting works, the present works had cost £35,000, and he was going to ask for £5,000 or £6,000 for increasing those works. It was proposed to put down one 300-h.p. engine, and two 80-h.p. engines. The works now were able to supply 3,500 amperes, and with this addition would produce 1,800 more. The proposal to light the Town Hall was before the Council, and would probably soon be carried out, and the committee had a large number of demands for the electric light current. They had not pressed the matter, for they had the interests of the gas works—in which a large amount of capital had been sunk—to preserve, but the increased demand was consequent upon the superiority of the electric light. He apprehended that the Council would wish that the committee should keep pace with these demands. The two smaller engines were required to obviate the necessity of running the larger engine in the morning, when the demand was at its minimum. By this means the very uneconomical proceeding of running a large engine at a low power was rendered unnecessary. Mr. Galloway objected to additional expenditure until the station paid. Mr. Alderman Feather objected to the expense of maintenance. He understood that they were at present consuming 6lb. of coal per hour for each indicated horse-power, which he had been informed could be reduced to 1½lb. per hour He was further given to understand that a proposal had been made to the Halifax Corporation to supply a complete electric plant and guarantee a net profit of 7½ per cent. ; and if that could be done at Halifax, it could be done at Bradford. Alderman Priestman, in reply to Mr. Galloway, said he considered the proposed expenditure on the electric light station a wise expenditure. Up to the 31st of December, 1889, the loss on the electric lighting works was £1,079 ; during the half-year ended the 30th of June, 1890, the loss was £732 ; and from that date to the 30th of December, 1890, the loss was £315. That showed clearly that they were now on the verge of making the works pay, and from the facts and figures he had given to the Council he had not the slightest hesitation in saying that by the end of next year those works would be paying more than the interest on the money expended on them. Alderman Feather's statement as to the consumption of coal was not correct. The quantity of coal consumed depended on the quality of the coal used, and instead of the consumption reaching 6lb. per hour, it was more nearly about 2½lb. to 2¾lb. per hour. At certain periods, when only a very slight load was upon the engines, the consumption might be 6lb. per hour per horse-power, and that was the reason why he was asking for two small engines. He appealed to the Council to complete the installation in the way proposed by the committee. He believed that it would very soon be the duty of someone to ask the Council to spend an additional sum of money on the electric light works, and that would be the best time to deal with the question of economy of fuel. He thought the committee was proceeding in the most economical course possible. There had been a complaint in some quarters about the committee not adopting the alternating current, and in answer to that complaint he wished to state that the direct and continuous current was the one most favoured by authorities on the subject, and was the one which would probably be generally adopted in the future. The resolution was carried.

UNDERGROUND MAINS.—VII.

THE SILVERTOWN SYSTEM.

The chief feature in the system of underground mains advocated by the India Rubber, Gutta Percha, and Telegraph Works, Limited, Silvertown, E., usually known as the Silvertown Company, is the insulated conductor itself, the exact material of the pipe or conduit in which it is laid being in their opinion of secondary importance, so long as it permits of the employment of a drawing in and out system, and is sufficiently strong to afford adequate mechanical protection to the cable placed in it. The experience of the Silvertown Company as cable manufacturers extends over a considerable number of years, and during this time they have paid a great amount of attention to the perfecting of the design and manufacture of electric light cables, with a view to increasing their efficiency and durability, and have made many experiments not only with indiarubber, but also with waxes and bituminous and resinous compounds, used either alone or in conjunction with fibrous material and lead casings. In addition to this, they have had the opportunity of practically testing other systems of insulation which have been brought before them, and the result of this experience has been in their case to impress them with the opinion that for a thoroughly reliable and durable system the cable itself must be insulated as though it were to be used under water, and must at the same time be capable of standing considerable variation of temperature and exposure to the atmosphere, and that it must not depend in any way on the pipe or conduit as a protection, except against mechanical injury. The material which has been found most suitable for fulfilling these conditions is vulcanised indiarubber; and notwithstanding the expense in the first place, it is stated that owing to the saving in maintenance, the total cost of a system of rubber cables during a number of years will compare favourably with that of any other system—*i.e.*, that if the annual cost of maintenance is capitalised and added to the first cost in each case, the vulcanised rubber cable will more than hold its own.

For underground work two classes of cable are made: one suitable for high pressures, such as 2,000 volts, and another for medium and low pressures, say, up to about 600 volts. Both classes of cable consist of stranded tinned copper wire, insulated with first pure rubber, and then vulcanising rubber of the best quality, great care being taken in the selection and preparing of the rubber, and in the applying it to the conductor. The core thus made is vulcanised, and protected by compounded tapes and braiding, which have been found to provide ample protection against damage from handling and drawing into pipes when ordinary care is taken.

Before proceeding to the description of the method of laying these cables, we may mention that the Silvertown Company lay very great stress on the testing of every length of cable before it leaves their factory, and have adopted the plan of sending out a copy of the test with practically all deliveries of cable. The tests are all made in water, with a testing E.M.F. of about 500 volts, and the insulation resistance given is that at 60deg. F., after one minute's electrification. In addition to this quantatitive test, they are now prepared to subject all cables required for high-pressure circuits to a breaking-down test, at the same or a higher voltage than that at which the cables are to be used.

With regard to the system of laying the cables, the Silvertown Company are decidedly in favour of a drawing in and out system, and never, we understand, use any other, although, of course, their cables are sometimes laid otherwise when the laying is not under their control. Their reasons for this may be briefly stated as follows: The drawing-in system allows of extensions being easily made without disturbing the surface of the ground, as a small cable can be drawn out and replaced by one with a heavier conductor, and extra cables can be drawn in as required, if the precaution has been taken at the first opening up of the ground of laying spare pipes—which can be done at a very moderate cost compared with that of opening up the ground each time, or that of laying cables with the full section of copper when there is no prospect of their being required for immediate use.

This system also lends itself to the localisation of a fault, should one exist, and to its repair, owing to the ease with which a faulty length of cable can be replaced by a good length. Although not tied to any one particular form of conduit, they consider that a conduit made of cast-iron socket pipes is the best, since it combines great durability with economy of space, and affords an excellent mechanical protection. No special attempt is made to keep the conduit watertight, but the pipes are laid with a dip towards the surface-boxes, the bottoms of which (if there are any) are perforated, and the boxes themselves set on rubble, or other loose material, to facilitate the drawing off of water, which, if allowed to become stagnant, might cause unpleasant smells.

The joints between the conduit pipes are made with rubber rings of circular section, like enlarged umbrella rings, and this method of making the joints has been found very satisfactory, being more expeditious than lead joints, and making a flexible line of piping, which is less likely to receive injury from any external pressure than a rigid line. Surface boxes of brick or cast iron, generally the latter, are placed at every sharp bend in the line of pipes, and also in straight runs at about every 100 yards, more or less, according to the size and weight of the cables.

The cast-iron boxes (Fig. 1) are provided with an outlet on each of the four sides shaped like the faucet of the pipes, and these, if not required for pipe connections, are closed by a plug, and with a lid consisting of a cast-iron frame which can be filled in with material similar to the surrounding

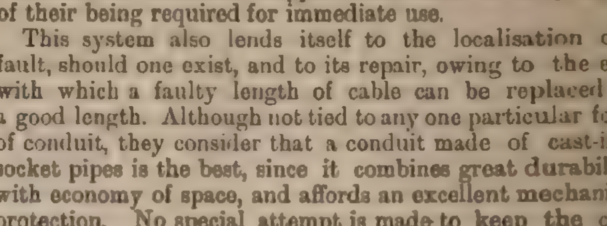

FIG. 1.—Drawing In and Joint Box. Silvertown System.

paving. Brick surface boxes (Fig. 2) are used where there are a large number of pipes, and where the box for any reason has to be of extra large size. For house services, smaller cast-iron boxes similar to those described above are used, or a length of pipe is replaced by a split T-piece of an enlarged sectional area (Fig. 3). As these pipes are laid, a wire is threaded through them and left in with its ends made fast in the surface boxes, ready to act as a hauling line when cables are to be drawn in. The cables are brought to the ground on drums, which are placed on stands near the surface boxes, so that they are free to revolve; the cable or cables are attached by a strong but smooth fastening to a rope, and this rope is pulled through the pipes by means of the hauling wire, and is itself used to guide the cable through. In straight runs the length of cable that can be pulled through at one time depends on its weight, but it is not often that this limit is reached, owing to the frequent changes of direction of the pipes, but when it is, and also at all sharp bends, the cable is brought up to the surface and coiled on the ground, the cable thus coiled being afterwards pulled through the next length of pipes in a similar manner. Soft soap or whiting is used as a lubricant to reduce the friction between the cable and the pipe, and if care has been taken during the laying to see that the way is clear, and no obstruction is left in the pipes, the cable can easily be pulled in without damage. With moderate-sized cables, such as are used on high-pressure circuits, two are drawn in together into each pipe, but with the heavier cables used on low-pressure systems, it has been found advisable to provide a separate way for each where objections do not arise, as they may in the case of alternating currents. On high-pressure circuits a continuous insulation is imperative throughout all the underground system, and the Silvertown Company therefore consider it advisable to vulcanise the rubber insulation of

all joints underground, and with a view to facilitate this operation, they have devised a portable vulcanising kit, and drawn up a set of instructions for the proper making of these joints.

Although too long to give in full, a brief *résumé* of these instructions may be of interest, together with a description of the special "cure" employed. This latter consists of a cast-iron T-shaped box made in halves, with flanges so that they can be bolted together. Three

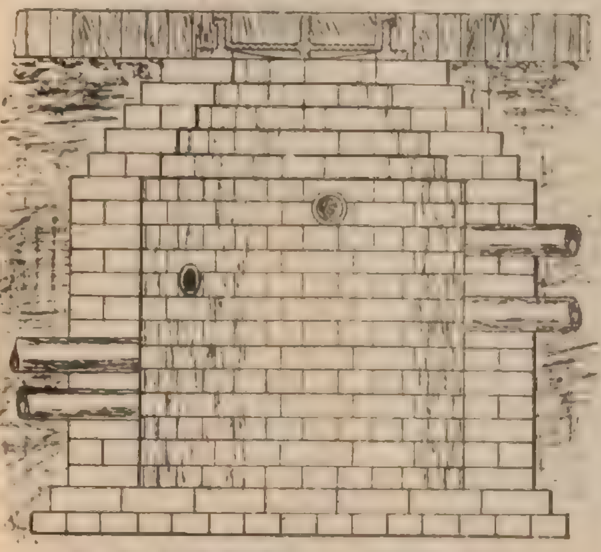

FIG. 2.—Brick Manhole. Silvertown System.

circular openings are provided, one at each end of the box, and one at the end of the T-piece, for the introduction of the cables to be jointed, and an opening is provided in the top half for pouring in molten sulphur, and a cock on the bottom half for drawing it off at the end of the cure. The joint between the two halves of the box is made with asbestos packing, and those at the places where the cables enter, by wrapping the cable with a strip of common rubber. The sulphur is melted in a separate pot, and when all is ready is poured into the cure, the temperature being maintained by placing one or more spirit lamps under the cure, and observed by a thermometer introduced into the sulphur through the hole

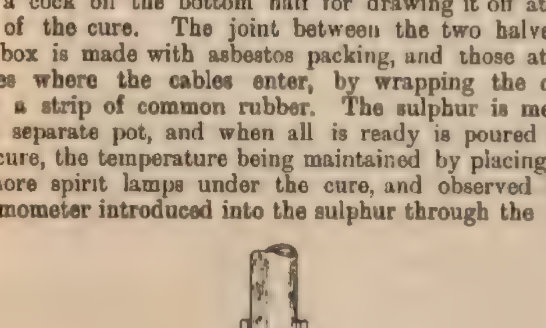

FIG. 3.—Branch Junction. Silvertown System.

in the top of the box. With regard to the actual making of the joint, the following method is recommended: The copper joint is carefully soldered with resin as a flux and finished smooth and clean. The ends of the rubber, which have been exposed during the making of the copper joint, are then pared down to as long a taper as can be made, and the conductor is lapped tightly with one or more layers of pure rubber strip, which extend partly over the tapered surface of the original insulation. One or more layers of vulcanising rubber are then put on over the full length of the joint, care being taken to lap them so as to exclude air. The joint then made is tightly bound up with prepared tape, is then covered with a piece of sheeting, making a longitudinal seam, and firmly bound over all with selvedge tape. The sheeting and selvedge tape act as a mould to keep the joint in shape during the vulcanising process, and are removed again when this is completed. The two halves of the cure are then placed around the joint and are bolted together, the joints being made tight in the manner described above. Molten sulphur is poured in, and is maintained at a temperature of about 290deg. to 300deg. F. for half an hour, by which time the cure is complete; the sulphur is then drawn off, the cover removed, and the wrappings taken off the joint. If the rubber is properly cured, it should, when cold, be springy and yield to the pressure of the thumbnail, but no mark should be left when the pressure is removed. The joint is then finished by covering it with prepared tape as a mechanical protection.

The importance of good jointing is a matter which the Silvertown Company specially insists on, and it certainly seems rational that when a continuously insulated cable is employed no uninsulated conductor surface should be allowed underground. A system of separate short lengths of insulated cables into each house, such as adopted by Mr. Bailey for the Metropolitan Company, offers, however, very great advantages in the matter of testing, and facilitates the withdrawing and replacing of cables, and we understand that the Silvertown Company fully appreciates the advantage of such a system, where the connections can be made at the primary fuse-boxes in the householder's cellar, and where proper precautions are taken to prevent excessive surface leakages.

The Silvertown Company claims that it has an excellent record for underground work, as wherever their cables have been used and laid in accordance with their recommendations, the result has been eminently satisfactory. The amount of work done by them may be judged by the list we give below of the supply companies in Great Britain who are employing their cables, in addition to which they have also laid them for a large number of private installations, amongst them the lighting of their own factory, where rubber cables have been in use in concrete trenches for about eight years. On the Continent also the high-tension distribution in Paris, Tours, Madrid, and Barcelona is almost exclusively carried out with their cables, made either at Silvertown or Persan, and large quantities have been shipped to India, Australia, and South America for local supply companies:

London Electric Supply Corporation; Westminster Electric Supply Company; Metropolitan Electric Supply Company; House-to-House Electric Supply Company, West Brompton; Brighton and Hove Electric Supply Company; Crompton and Co., Chelmsford; Eastbourne Electric Supply Company; Muir, Mavor, and Coulson, Glasgow; Hastings and St. Leonards Electric Company; Newcastle-on-Tyne and District Electric Light Company; and Woking Electric Light Company.

CREOSOTING TIMBER.*

BY E. J. SILCOCK, A.M.I.C.E., F.G.S., BOROUGH ENGINEER, KING'S LYNN.

In bringing the subject of creosoting timber before this association it is hardly hoped that any new matter will be introduced. The whole subject has been most fully discussed by Mr. S. B. Boulton, A.I.C.E., in his paper on "The Antiseptic Treatment of Timber," read before the Institution of Civil Engineers, and the author acknowledges the great assistance which that paper has been in the preparation of the present communication. Although the subject has been so fully dealt with, the author finds no generally accepted practice, and having had some little experience of the work, hopes by means of this paper and a fresh discussion to ensure a greater uniformity in the specifications issued by the members of the association. There is at present such a variety in the requirements of different specifications that it is practically impossible to comply with all with the same plant. The result of this no doubt very largely is, that when firms are putting down creosoting plant they only provide for the requirements of the majority of their customers. Now, unfortunately, this majority is usually that section which is somewhat lax, and contractors take alike all orders with the hope that they may be able to get their work passed even in cases where their plant cannot carry out the specification. At present a good specification and thorough inspection are met with the declaration that

* Paper read before the London meeting of the Association of Municipal and County Engineers.

there is no available plant in the immediate neighbourhood, and that we must therefore be satisfied either with getting what we can or send to a distance. Now, independently of the extra expense, this alternative renders thorough inspection extremely difficult, and is generally opposed by contractors or our clients. We all know there can be practically very little difference in the labour or time required to do the work efficiently or the reverse, and it is therefore evident that if there were a more uniform system of specifying, combined with more rigid inspection, the supply would soon meet the demand, for creosoting firms would speedily put down suitable plant for the work. No difficulty would then be experienced in getting what we require. The importance of having timber creosoted when it is to be subjected to the influences of the weather hardly admits of argument. Abundant evidence can be produced to show that where efficiently done the process at least doubles the life of timber. One or two facts on this head will suffice. The average life of an ordinary uncreosoted telegraph pole is, on the authority of Mr. W. H. Preece, F.R.S., chief electrician to the Post Office, about seven years, whereas a line of creosoted poles about 20 miles in length put down in 1848, were taken up in 1883, and were then perfectly sound. Again, on the Great Western Railway it is found that the life of uncreosoted sleepers is five years, and that of creosoted sleepers eight to ten years, and many last to double that length of time. In tropical regions timber is very rapidly destroyed by marine insects, more particularly the Teredo Navalis and Limnoria. On the Pacific and Atlantic shores of the States it is found that uncreosoted piles are destroyed in two years, whereas creosoted piles last from five to six years. Since then the process doubles the life of timber, and the cost of treatment is not more than 25 per cent. of the prime cost of the material, it is a self-evident proposition that all exposed timber should, where possible, be creosoted. If we add the cost of carpentry, driving and fixing the material to the prime cost, the case for creosoting is even stronger, in most cases not adding more than 10 per cent. to the cost of complete work. Many works carried out by members of this association involve the use of large quantities of timber, so that the importance of the subject in this regard should not be overlooked.

Without going very deeply into chemistry, it may be stated that what is commonly called creosote is that portion of the products of the destructive distillation of coal tar which is heavier than water. When coal tar is distilled three groups of products are produced—viz.: (A) crude naphthas or oils lighter than water; (B) dead oil or creosote heavier than water, and (C) pitch. These oils contain many constituents, between which there is no clear dividing line, but the constituents of creosote may be divided into three groups: (1) the phenols or most volatile portions, the chief of which is carbolic acid; (2) the group the principal of which is naphthalene; (3) the least volatile or bituminous portions which distil over at a temperature beyond 535deg. F., the principal of which is anthracene. Decay of timber is brought about chiefly by three agencies—viz., by the fermenting of the albumenoids of the sap, by the admission of water into the cells of the wood, and by the attacks of insects. In all three directions creosoting acts as a preservative. The carbolic and other acids in the creosote coagulate the albumen of the sap and arrest the process of fermentation; the heavier portions of the creosote enter and fill up the pores of the wood, and so prevent the entrance of moisture; and the powerful smell of the creosote, and probably its flavour, deter insect life from penetrating the wood and taking up its abode in its cells. The modern germ theory has entirely revolutionised the accepted ideas of scientists on the subject of the putrefaction of animal and vegetable tissues. It was formerly believed that the coagulation of the albumenoids in these organic tissues permanently prevented putrefaction. It has, however, been demonstrated that the coagulation of albumenoids is not permanent, and that antiseptics (germ killers), which (like carbolic acid) are themselves soluble in water and volatile in air, are removed from their albuminates by the action of water and air, and so permit germ life or fermentation to set up. M. Pasteur *has now clearly* demonstrated that germs are the agents of decomposition, and that in their absence organic decomposition does not take place. Various kinds of fermentations, such as yeast, vinegar, beer, etc., have been traced by him to a specific germ, which can be detected and cultivated and relied upon to produce its special kind of fermentation. In attempting, therefore, to preserve timber, we must select such substances as will be capable of killing these organisms known as germs, and will produce such conditions as to prevent their development. Carbolic acid (a phenol), though a very powerful germ killer or antiseptic, is unfortunately very volatile in air and soluble in water, and several investigators have proved by analysis that it is present only in extremely small quantities in timber 12 months after treatment by creosoting. It would therefore appear that the extreme value of this acid, which was formerly so much insisted on, is somewhat doubtful. Still, there can be no doubt that the coagulation of the albumen which is effected at the commencement of the process is of value, especially as air and water are afterwards prevented from reaching the interior of the wood by the more bituminous portions of the creosote oils. The naphthalene group forms a large proportion, about 60 per cent., of the constituents of creosote oil, and has antiseptic powers, though they are less energetic in their immediate action than carbolic acid. Naphthalene itself is, however, practically insoluble in water, and is very much less volatile in air than the phenols, and at ordinary temperatures it solidifies and tends to prevent the escape of the more volatile portions of the oils, and the entrance of moisture and micro-organisms. Dr. Tidy made experiments with a view to determining the extent of volatilisation of naphthalene, and he was led to the conclusion that the loss was very rapid for a day or two, but after that period it decreased to almost nothing. This result has, however, not been verified by Dr. Clark, who recently read a paper on the permanency of creosoting agents. He found that volatilisation went on to a large extent for a very considerable period. This view accords with actual experience, for it is a very common thing to see the soil round sleepers discoloured by creosote 12 months after they are laid. Naphthalene must not therefore be looked upon as an absolutely stable body. Experiments are now being made in America with naphthalene alone as a preservative, but so far as the author knows no results have yet been published. There is, however, a practical difficulty in use of pure naphthalene, as its melting point is about 173deg. F., and therefore it must be raised to a very considerable temperature before injection.

Turning now to the heavier or more bituminous portions of the creosote—viz., those which distil over at a temperature beyond 535deg. F.—we find that their function is almost entirely confined to forming an impervious skin or shell round the timber, and to this Dr. Tidy attaches special importance, for in his specification he stipulates that not less than 25 per cent. of the oil should distil beyond 600deg. F. Creosote oils are divided into two classes, known as London or heavy oils, and country or light oils. The London oils are those obtained from coal tar made from Newcastle coal, whereas the country oils are made from coal from the Midland coalfields. The London tars yield less tar acid or phenols than the country tars, but they contain more naphthalene. In ordinary commercial creosote the phenols vary from 3 per cent. to 18 to 20 per cent. In considering the constituents for which it is necessary to specify in creosote, we find that formerly as much as 12 per cent. of phenols was sometimes specified. It appears, however, that a very much smaller proportion of phenols will effect the coagulation of the albumenoids which is at first required, and that if a greater quantity is provided it very quickly volatilises. It should be noted that the quantity of tar acids should bear some relation to the quantity of sap in the timber, so that for telegraph poles, hop poles, and similar young or sappy wood, the tar acids should be greater than for deals and whole timbers. Generally, however, it appears now to be the opinion that if 5 per cent. of tar acids are present, it will be sufficient for ordinary cases. The percentage of the heavier or pitchy constituents of the oil is also important. It is this portion which blocks up the pores of the timber. Dr. Tidy, as previously stated, specifies 25 per cent. of these constituents which do not distil under 600deg. F. This, the author

submits, is impracticable, as from several analyses of commercial creosote he finds that the residue at 600deg. varies from 8 to 15 per cent. Probably 25 per cent. over 535deg. F. is about as much as is obtained in practice. At the same time the oil should be completely liquid at a temperature of 100deg. F., or it cannot be injected sufficiently freely into the fibre to form the skin or shell before referred to. No ammoniacal water should be present in the creosote, as it has an injurious effect upon the timber. It is the practice of some firms to mix crude tar with their creosote oils, especially if they use country oils. This course should be deprecated, as the crude tar contains all the oils lighter than water, which are of no value for creosoting purposes, and also a large quantity of pitch, the carbon in which prevents the oil from penetrating the fibres of the timber. Occasionally bone oils and mineral oils are used for creosoting purposes, but as they contain no antiseptics they are unfit for the purpose, and should be rejected.

In America creosote proper—*i.e.*, oils obtained from the distillation of wood—are largely employed. This, no doubt, arises from the fact that timber is much cheaper in America than in this country, whereas coal is much more expensive. Wood creosote is much more uniform in its constituents than coal-tar creosote, and is less volatile and soluble when exposed to air and water; it also contains no ammonia, which is considered to hasten decay. It is said to be much more effective in protecting timber from marine insects than coal-tar creosote. The quantity of oil to be injected varies in most specifications from 6lb. per cubic foot to 12lb. per cubic foot. Generally, it may be said that the more creosote is injected, the more efficient the process; but, of course, when this principle is carried to excess the expense becomes prohibitive, and it is found that, except in the case of very young timber or very small scantlings, 12lb. per cubic foot is about the practical limit. The author has, however, seen Baltic sleepers, 10in. by 5in., which absorbed over 20lb. per cubic foot, so that although for large scantlings it may not be possible to inject such a large quantity as this, still there is no practical difficulty in getting 10lb. to 12lb. injected into any timber of the coniferous class. The specific gravity of creosote being about 1·05, a gallon weighs 10½lb., and the author submits as a standard that one gallon per cubic foot should be required, as it is more convenient to measure the quantity in gallons than in pounds. The processes by which creosote is injected into timber in this country are four in number—viz., the open tank process, Bethell's process, Boulton's process, and Blythe's process. These will now be described in the order named. Of the open tank process very little need be said; it consists merely of steeping the timber in creosote in an open tank. Unless the process is carried on for a very lengthened period, say, several weeks, and the oil is kept at a high temperature, it does not penetrate beyond a very short distance from the surface of the timber, unless there is a large proportion of sap wood, or the scantlings are very thin. A few shavings with a plane will entirely remove all traces of creosote from the heart wood. This process, therefore, cannot be said to be very satisfactory.

In Bethell's process the timber is placed in closed iron cylinders, varying in length from 40ft. to 80ft., and in diameter from 4ft. to 7ft. The cylinders have hemispherical ends, one of which is loose and is suspended from an iron arm fixed to the cylinder, so that during charging and discharging it can be swung on one side. The cylinder is provided with a faced flange at the end which opens, and the hemispherical end is secured in its place by screw-clamps which clamp the end to the cylinder flange. The creosote is contained in a tank or tanks underneath, or to one side of the cylinder, and the tank and cylinder are connected by an iron pipe led from the bottom of the cylinder, and provided with a stop valve. Hot-water or steam pipes are taken from a suitable boiler and furnace into the creosote tanks, so that the temperature of the oil can be raised to 150deg. F. before admission to the cylinder. An air pump and a pressure pump, driven either by steam or hydraulic power, are placed in a shed adjoining the cylinder; the air pump being connected to the creosote cylinder by suitable piping, and the pressure pump drawing its supply of creosote from a tank and discharging it into the creosote cylinder. It is preferable, if possible, to have a separate tank for the pressure pump to draw from, as the quantity of creosote injected can then be more accurately measured. The process is then carried out as follows: The timber is placed in the cylinder, the hemispherical end fixed, and the air pump is set to work to exhaust the air from the space unoccupied by the timber and from the pores of the timber, the valve between the cylinder and the creosote tank being closed and a vacuum of about 10lb. per inch being maintained. At the end of an hour the valve is opened, and the atmospheric pressure causes the creosote to rise up the pipe connecting the cylinder and tank, and fills up all spaces in the cylinder not occupied by timber. When the tank is full the air pump is stopped and the pressure pump is set to work, and creosote is pumped in under pressure until the required quantity has been injected into the wood. The time occupied in this operation depends on the quantity to be injected and the state of the timber, varying from 10 minutes to as many hours, the pressure varying from 30lb. per square inch up to 120lb. per square inch. The quantity to be pumped is determined by multiplying the cubical contents in feet of the charge of timber by the specified quantity of creosote per cubic foot. The tank from which the pressure pump draws its supply is provided with a gauge by means of which the quantity pumped can be measured. When the required quantity of creosote has been injected the pump is stopped, and the valve connecting the cylinder with the creosote tank is opened, and the oil is allowed to drain back into the tank. The cylinder is then opened and the charge of timber withdrawn.

Boulton's process differs from Bethell's in that the temperature to which the oils are raised in the creosote cylinder is 212deg. F. to 220deg. F., instead of 120deg. F. To effect this, steam-pipes are introduced into the creosote cylinder. The plant required is similar to that for Bethell's process, except that besides the above-mentioned steam-pipes, a steam-dome is fitted to the cylinder, and a surface condenser to the air pump. The principle on which the process rests is the fact that whereas the boiling points of the creosote oils vary from about 250deg. F., to 700deg. F., that of water is 212deg. F., consequently all the moisture present in the timber is driven out in the form of steam by the heat of the oils, and this steam is exhausted by the air pump and subsequently condensed without any appreciable quantity of creosote being evaporated. At the same time the timber does not suffer from this excessive heat, because that heat is applied through the medium of the oils, and is not a dry heat. The process is carried out in the following manner: As soon as the cylinder is charged with timber and closed, oil is introduced until the cylinder is nearly full, and the temperature raised to 212deg. F. to 220deg. F. The air pump is then started, and the air and steam exhausted until no further water flows from the condenser. The pressure pump is then worked until the required quantity of creosote is injected. The timber absorbs a large quantity of oils by displacement as the moisture is driven out, so that the pressure pumps have less work to perform, and less oil has to be forced in by that means—a clear advantage over Bethell's process. The total quantity of oils injected is the sum of the quantity absorbed by displacement and the quantity injected under pressure. The first of these quantities is ascertained by completely filling the creosote cylinder and dome with oil before the air pump is started, then reading the gauge in the creosote tank. A small quantity of oil is then run back from the cylinder into the tank, to secure a space at the top of the cylinder in which the air and steam can gather. When the exhausting process is finished, the cylinder and dome are again filled and the gauge again read. The difference between the two readings gives the quantity required—*i.e.*, already absorbed. The second of these quantities is the balance required to comply with the specification, and this is then pumped in by the pressure pump from a tank fitted with a contents gauge. Boulton's process is a very marked improvement on the older system, more especially when treating timber which has been water-seasoned, or which is very green. To put it in plain words, the timber is boiled in the creosote, and by that means all the water and most of the sap are removed, as well as

the air from the cells of the timber, and the creosote oils take their place. The advantages of the process are not so marked when treating deals or other sawn timber, which is usually fairly well seasoned and tolerably dry, but it is common practice to take Memel timber and pitch pine out of seasoning ponds, and put straight into the creosote cylinders. In such a case Bethell's process cannot materially reduce the quantity of water in the time; merely exhausting the air and reducing the pressure on the outside of the timber will not extract any large quantity of moisture, and when the pressure pump is put to work and the creosote forced into the timber, the water is only driven more deeply in, and then sealed in by the bituminous portions of the oils. It will thus be seen that it may be quite possible, by using Bethell's process, to fix in the timber an element of danger to its durability.

(To be concluded.)

THE DARMSTADT CENTRAL STATION.

The Darmstadt municipal authorities, if they have not yet made their central electric light station pay, have at least done good service in publishing very full reports of their accounts since the commencement of the undertaking in 1888. The following analysis of the report is given in the *Revue Industrielle*, and as it gives very full details both of the first cost of installation and of the various items of receipt and expenditure for the time the station has been working, these details, although applying to continental practice, cannot fail to be of considerable interest to all electrical engineers.

Distribution.—The network of conductors extends over 23 streets and squares, having 20 junction-boxes. The network is fed by feeders leading direct from the station to the points of distribution. The mains used are of lead-covered cable, armoured with iron on the outside. The following are the different sections and lengths both of street mains and service mains:

STREET MAINS.

Lengths	973·0	metres	of conductors of	25	mm^2 section.
”	4,012·0	”	”	35	”
”	5,697·5	”	”	50	”
”	6,668·8	”	”	70	”
”	5,932·6	”	”	95	”
”	3,405·0	”	”	120	”
”	962·2	”	”	150	”
”	2,449·2	”	”	185	”
”	2,244·7	”	”	310	”
”	190·0	”	”	400	”
”	913·4	”	”	500	”
”	370·7	”	”	625	”

33,819·1 total length.

SERVICE MAINS.

Lengths	272·4	metres	of conductors of	6	mm^2 section.
”	1,168·8	”	”	10	”
”	1,072	”	”	16	”
”	354	”	”	25	”
”	265	”	”	35	”
”	66	”	”	50	”

3,198·2 total length.

Total of the whole length of mains, 37,017·3 metres.

The mains have been tested at several points without any diminution of the insulation being found.

Plant.—Of the engines, dynamos, boilers, and accumulators, the first, the report states, have worked well, but trouble has been experienced with the accumulators. The glass vessels frequently cracked, and have finally been replaced by wooden cases, and the whole battery removed from a chamber partitioned off from the engine-room to a separate room. Since this time (August, 1889) the accumulators have acted with entire satisfaction.

Meters.—Each installation is fitted with an Aron meter. On August 1, 1890, 113 meters were in use.

Customers.—For the year 1889-90, the number of customers, including the theatre, was 125, using 576 lamps of 10 c.p., 2,594 lamps of 16 c.p., 1,263 of 25 c.p., and 24 lamps of 35 c.p.; also 26 arc lamps of six amperes, and 24 arc lamps of 10 amperes, equal in total to 5,493 lamps of 16 c.p. There were, besides, two motors of $1\frac{1}{4}$ h.p. each.

(The theatre alone has 489 lamps of 16 c.p., 1,210 of 16 c.p., 787 of 25 c.p., and 18 arcs of 10 amperes.)

During 1890 this list received the addition of 15 customers, with 15 10-c.p. lamps, 291 16-c.p., 43 25-c.p., 6 35-c.p. lamps, and 4 arcs.

The receipts since the time of working—1st September, 1888, to 31st March, 1889—for sale of current were 43,234·55 marks (say, £2,161), consisting of:

Private lighting.................	23,175·10 marks	(£1,158).
Theatre of the Grand Duke ...	20,059·36 ”	(£1,002).

Under these conditions, one incandescent lamp, reduced to an average of 16 c.p., has brought in for supply of current during eight months:

(*a*) For private lighting: 11·34 marks (the mark is practically 1s.), corresponding to a mean period of lighting of 283·5 hours per annum.

(*b*) For the theatre: 6·58 marks, corresponding to an average service of 164·5 hours per annum.

For the year 1889-90 the receipts showed 55,822·84 marks, comprising:

Private lighting..................	32,884·08 marks.
Theatre lighting	22,938·76 marks.

A 16-c.p. lamp therefore brought in during 1890:

(*a*) Private lighting, 13·44 marks, corresponding to an average service of 336 hours per annum.

(*b*) Theatre lighting, 7·53 marks, corresponding to a service of 188·3 hours per annum.

Cost of Production.—The reports show that the consumption of fuel in 1888-89 was 3·02 kilogrammes (6·64lb.) per horse-power hour. In 1889·90 this became 2·46 kilogramme (5·41lb.).

The fuel exclusively used was coal from the Pluton mines. In 1888-89 the consumption was 509,005 kilogrammes (1,119,810lb., or 500 tons), which gave in clinkers and ashes, etc., 34,884 kilogrammes, or 6·85 per cent. In 1889-90 the consumption was 545,326 kilogrammes (531 tons), with a residue of 26,507 kilogrammes, or 4·86 per cent.

The consumption of water for boiler supply and cleaning according to the registration of the water meters, was 4,593 cubic metres; and in 1889-90, 3,917 cubic metres.

As regards the four engines, the number of hours worked was 3,295 in 1888-89, and the total output 841,973 ampere-hours, 168,584 horse-power hours. In 1889-90 the hours of working were 4,902, total output 1,108,801 ampere hours, or 221,770·2 horse-power hours.

The following are the figures of the work done by the accumulators in 1888-89, from November to March:

Charge........................ 118,480 ampere-hours.
Discharge .... 73,677 ampere-hours.
Mean efficiency in ampere-hours, 62·1 per cent.

In 1889-90, from 1st April, 1889, to end of March, 1890

Charge.......................... 266,610 ampere-hours.
Discharge .... 154,198 ampere-hours.
Mean efficiency in ampere-hours, 57·8 per cent.

The smallness of the use made of the battery is explicable, in the first place, to the alterations mentioned above, but, above all, for the reason that the large battery had to be reserved for the theatre in order to assure light, in case of need, from 6.30 to 10 p.m.—*i.e.*, just at the moment when it might be most advantageously employed. After the closing of the theatre the accumulators light the town, and are working at the maximum to 11.30—that is, for an hour at most—when they furnish all the current. After 11.30 p.m. the consumption is rapidly lowered, and remains stationary until 8.30 a.m. next morning. After this the battery is again used for about an hour to furnish a maximum current. As it is always in the morning that the rehearsals take place, for which the lighting is very

variable, the battery must be at once charged to its full capacity, in order to furnish any lighting that may be necessary. With another arrangement the dynamos might have been run all the morning, which would be a good deal cheaper than the use of the batteries, and the battery need only be charged sufficiently for ordinary requirements.

Financial Statistics.—The following are the figures given in the report of the cost of construction :

Central Station.	Marks.
Steam engines	51,750·10
Dynamos	49,887·17
Accumulators	22,309·66
Movable cranes	2,706·42
Boilers	39,908·25
Instruments and apparatus	39,968·44
Total (marks)	206,530·04
Mains.	
Cost of conductors	199,920 63
Laying	10,912·46
Junction-boxes	6,440·93
Total (marks)	217,274·02
Buildings.	
Cost of sites	50,055·35
Generating station	62,026·94
Heating by steam	976·83
Front of building	40,470·93
Accessories	4,970·37
Total (marks)	158,500·42
Management and General Expenditure.	
Management of works	31,390·97
General expenditure	9,569·31
Total (marks)	40,960·28
Incidental Expenses.	
Cost of installations at customers	36,806·53
Telephone	84·71
Total (marks)	36,891·25
Summary.	
According to the figures above the cost of construction amount to	660,156·01
From this are reimbursements for installations carried out	43,522·24
Leaving (marks)	616,633·77

The customers have to pay the necessary charges for laying the current on to the house, for the running of all wires inside the entrance of the house, as well as all necessary fittings. For the meters, which are lent by the town, 5 per cent. of their value is to be paid as hire. The normal price of one 16 candle-power hour is four pfennig, equal to just under ½d. The charges for incandescent lamps of higher candle-power, and of arc lamps, are either reckoned proportionately to the consumption of current or the candle-power.

After the station had been put into operation it was decided, besides this, that the customer must pay for all arc carbons used as well as for the cost of these lamps themselves, while the incandescent lamps were to be supplied and renewed by the town. Against this the Municipality levied an annual tax of six marks per incandescent lamp of 10 c.p. to 50 c.p., and of 25 marks per arc lamp. These conditions were not approved by the customers, and were afterwards modified (1st September, 1889), enacting that the customers must procure not only the arc lamps and their carbons, but also the incandescent lamps, or rather buy them at the electric station, the tax for lamps being altogether suppressed. At the same time a minimum period of lighting was enacted, corresponding for a 16-c.p. lamp in private houses to 0·6 of an hour a day, and in shops and factories to one hour a day. The other incandescent lamps, and the arc lamps, have proportionate minimum periods. The subscriber who has not paid for the full minimum is charged the difference at the end of the year. On the other hand, the following rebates are given, taking the 16 c.p. as basis.

Hours of service.	Rebate.
800 hours a year per lamp	5 per cent.
1,000 " "	7½ "
1,200 " "	10 "
1,500 " "	12½ "
2,000 " "	15 "

From the table of the "active" and "passive" capital in the electric light station on April 1, 1890, as well as the statement of receipts and expenditure of the 16 candle-power hour taken as basis, it appears as if the Municipality would have to subscribe yet further to the cost of maintenance before the installation is on a paying basis.

Statement of Accounts, April 1, 1890.

1. Active.	Marks.
Engines, boilers, dynamos, cranes, apparatus, and instruments	189,388
Accumulators	22,734
Installation material	5,208
Mains	243,753
Buildings	164,688·93
Provision of reserve material, installation stores, warming apparatus, etc.	11,379·86
Total (marks)	637,151·79
2. Passive.	
Capital : Loan July 1, 1888, at 3½ per cent., 627,500, less sum deducted for 1888-9, 3,137·50	624,362·50
Loan at 4 per cent. from Municipality, subvention for extraordinary expenditure	1,409·43
Funds for maintenance provisionally put at the disposal of the electric light fund	11,379·86
Total (marks)	637,151·79

Statement of Receipts and Expenditure, 1889-90, *including Accessories Revenue.*

1. Receipts.	Marks.
Sale of current	55,822·84
Lamp tax	6,907·81
Hire of meters	837·53
Sale of arc lamps and carbons	539·74
Rent received for buildings and sites	900 00
Various receipts	226·26
Charge for house installations	2,513·56
Total receipts (marks)	67,747·74
2. Expenditure.	Marks.
Interest on capital	21,907·50
Sinking sum on loans	3,137·50
Salaries and wages	17,284·09
Office expenses	929·27
Commissions	45·48
Taxes and contributions	1,005·15
Maintenance of buildings, etc.	337·90
Maintenance of machinery	839·15
Consumption of fuel and water	11,674·45
Cleaning material and oil	1,432 42
Lighting of station	1,509·11
Maintenance of underground mains	14·53
Manufacture and maintenance of meters	1,013·79
Manufacture of incandescent lamps	8,323·86
Manufacture of arc lamps, etc.	454·67
Maintenance of instruments and tools	162·37
Cost of house installations	2,130·12
Renewal funds	12,472·11
Total expenditure (marks)	84,073·47

The hour of service for one 16-c.p. incandescent lamp costs four pfennig, or ½d., so that for a sale of current of M. 55,822·84, the number of lamp-hours is 1,395,571.

It results, from above, that the cost price per 16 c.p. lamp-hour at the customer, deducting the accessory receipts, is :

$$\frac{84{,}073{\cdot}47 - 11{,}924{\cdot}90}{1{,}395{,}571} = 5{\cdot}1069 \text{ pfennig, or about } 0{\cdot}6\text{d.}$$

They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, [illegible] them, believing that they will get full val[illegible] their n[illegible]

[illegible] sent on [illegible]

CARLOW.

The recent election at Carlow has made prominent at the present moment a town which seems destined to become still more prominent, being the first Irish town to recognise and act upon the conclusion that the waste water power near a town might with advantage be utilised to provide light. The ordinary Englishman, used to the high pressure of business life, can hardly realise the exact position of such towns as Carlow in the ranks of progressive towns. To him, accustomed as he is to noise and bustle, the quietude of a prosperous, comfortable county town in the midst of a purely agricultural country is characteristic of Rip van Winkleism rather than of progress. But, on the other hand, those who live in remoter districts claim to recognise the go-aheadness of such places as Carlow. From whatever standpoint one views the situation, the fact remains that Carlow, for good or for ill, has taken a step which other places have talked about, and done, when the talk has ended, absolutely nothing. Situated some 56 miles south of Dublin, at the junction of the Burren with the Barrow, a considerable amount of water power is available. In years gone by, before Russia, America, and remoter parts of the earth supplied us with corn and flour, huge mills were actuated by the waters of the Barrow, and many another Irish stream. Now the mills are not worked. More modern milling appliances, added to the action of the Corn Laws, have driven the industry into other quarters. At Milford, some five miles from Carlow, stands one of these some time silent mills, its huge waterwheel inactive, and its gearing rusting away. The happy thought of using the waste power came to willing ears, and the result has been to install in a portion of the old mill, a dynamo-room, the machinery in which is at present driven by the old mill wheel, but which will soon be driven by turbines. With a little care we should imagine some three hundred horse-power can be obtained from the Barrow at this point, and two-thirds of that power would suffice to light every nook and corner of Carlow. The matter of the town lighting had long been a sore point. The Commissioners and the gas company did not quite agree, and latterly the town was lighted with oil—when the question was put to Mr. J. E. H. Gordon, who grasped the situation, made his proposal to the Commissioners, which was accepted, and within a few months of such agreement the work has been so far completed that the town lighting is regularly carried out. The formal inauguration of the lighting was, as is usual in such cases, made the pretext for a convivial meeting and dinner at the Town Hall on Monday last. Mr. Hammond, the newly-elected member of Parliament for Carlow, who has for 12 years been chairman of the Town Commissioners, delayed taking his seat in the House of Commons in order to be present at the inaugural banquet. This action tells its own tale as to the interest taken in the lighting. Deputations from Derry, Kilkenny, Portadown, and other places were also present to

inspect the works and the results at Carlow, and from what we could gather it is pretty certain that a number of towns will follow the lead given to them. It seems to us, then, that a good meed of praise should be given to everyone connected with this lighting. Certainly Waterford, Belfast, and other places in Ireland have not been behindhand in introducing the light, but here we have an inland town of only some six thousands of population, with no factories, initiating the use of its natural sources of power to give light; and undoubtedly throughout the length and breadth of Ireland this attempt will be closely watched, and wherever water power is running to waste, sooner or later it will be utilised. It is not our intention to enter into details of the lighting here—that must be reserved for another issue—but we may say briefly the current is generated at 2,500 volts pressure, carried by overhead wires to the town five miles away, and transformed down to 50 volts. The transformed current will, when the work is finished, feed a network of low-pressure mains, from which the arc lamps lighting the streets and the incandescent lighting the interiors of the houses will be fed. It is but just to say the price of gas in Ireland, averaging six or seven shillings per 1,000 cubic feet, makes the introduction of the electric light less difficult than it might otherwise be. There is some probability of being able to compete in price, and the other advantages of electricity should bring it well to the front. There is one question which might be strongly insisted upon by those interested in the welfare and development of industrial Ireland. The example of Carlow must lead to the examination of the possibility of using this waste water power in various industries by the use of electric transmission and of motors. Coal is comparatively dear in many parts of Ireland, while water power is abundant. Surely some means may be devised of placing this hitherto waste power in the hands of users in the quantities they desire.

PROVISIONAL ORDERS.

According to the Board of Trade report just issued, 70 applications were made during the year for provisional orders. Of this number 37 were made by local authorities, and 33 by companies or individuals. Twelve of the orders relate to London. Out of the 70 applications, 59 orders have been secured. The Board of Trade seems to follow an almost hard-and-fast rule, granting without demur an order to the local authority, and refusing an order unless backed with the consent of the local authority. At any rate, only one order so opposed has been granted—in respect of a part of the parish of St. Luke, Chelsea, to the New Cadogan and Belgrave Company. Strictly speaking, however, this opposition was not to the company's application, but to clauses inserted at the instigation of the London County Council. The appendix to the report is somewhat interesting. The boom of the early eighties is still remembered, and the passing of the 1882 Bill led to a rush for orders in 1883. In that year 69 orders were granted, and of these all but 13 have been worked. Several of the 13 have really proceeded with the work—the most prominent being St. Pancras and Bradford—but others have made no movement, or so little as to be unworthy the name of work. No licenses have been applied for during the past year; the two referred to in the preceding report—viz., Chelmsford and Bath—were duly granted, and, as our readers know, both these towns are lighted. Besides these, a total of 11 licenses have been granted which have not in some way been repealed. Between 1883 and 1889 only two orders remain unrevoked, while during 1889-1890, out of 86 orders granted only two have been revoked, so that at the present time 156 orders are running, in addition to 13 licenses.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

TOWNLEY'S DUPLEX ALARM.

SIR,—Having seen in your issue of to-day's date a description of Townley's duplex alarm, I should be greatly obliged if you could allow me space in your columns to state that as far back as March, 1886, I designed, and have used ever since, a practically similar combination (mounted on a neat carved bracket) comprising alarm, clock, battery, and, of course, an ordinary form bell, with the improvement of mercury cups to receive clock legs, and also, by turning a small knob, in the event of a breakdown, the electrical clock contacts were thrown out of gear and the ordinary mechanical alarm substituted.

I merely wish to show that there is no novelty attached to Townley's alarm.—Yours, etc., A. McMEEKIN.

Norwood, S.E., July 10, 1891.

SIR,—We notice in your current number a description of a new form of electric trembling bell, said to have been invented by Mr. J. Townley. We do not know when this gentleman may have invented his bell, but we beg to inform you that our Mr. W. R. Wynne patented a bell on this principle in 1885 (patent No. 7,373), and that we have been manufacturing and supplying these bells for some time. Our patent bell has fewer working parts than the one illustrated by you, and, as we believe, is a far more practicable and reliable article.—Yours, etc.,

BARNETT, WYNNE, AND BARNARD.

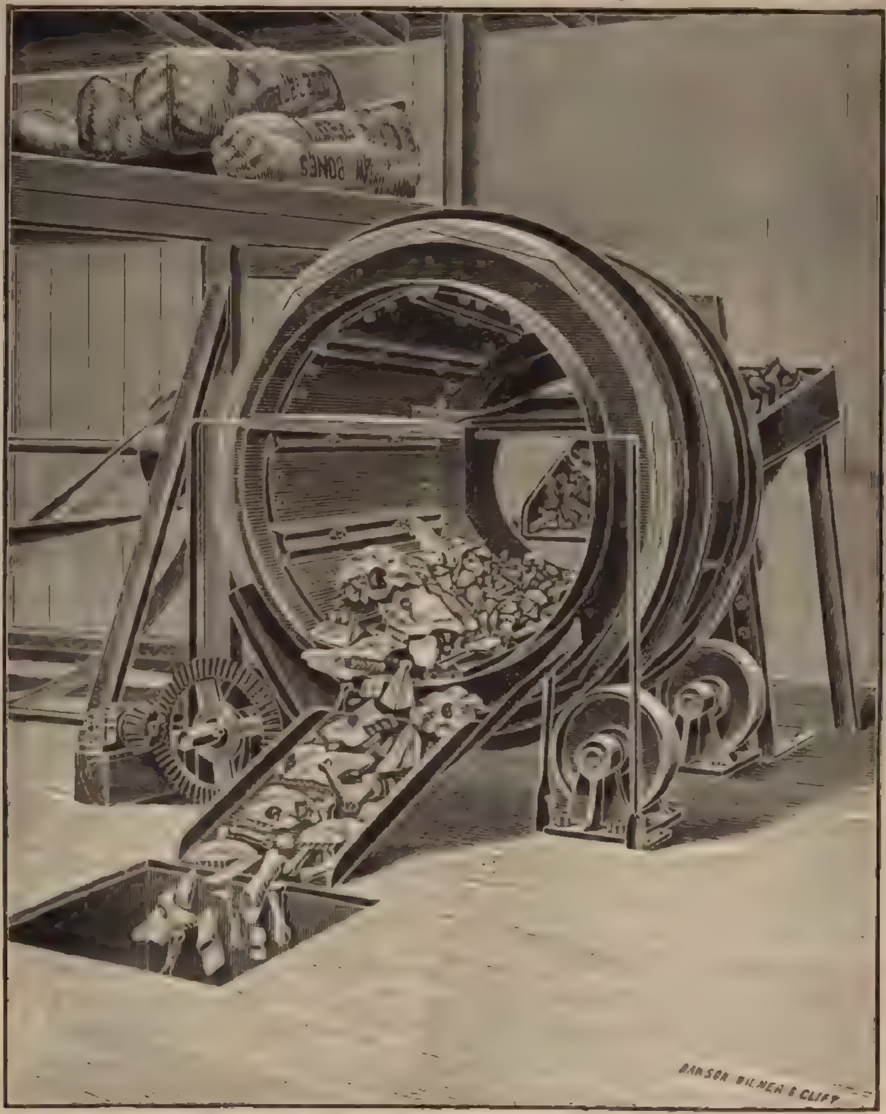
Newcastle-on-Tyne, July 10, 1891.

MAGNETIC BONE SEPARATOR.

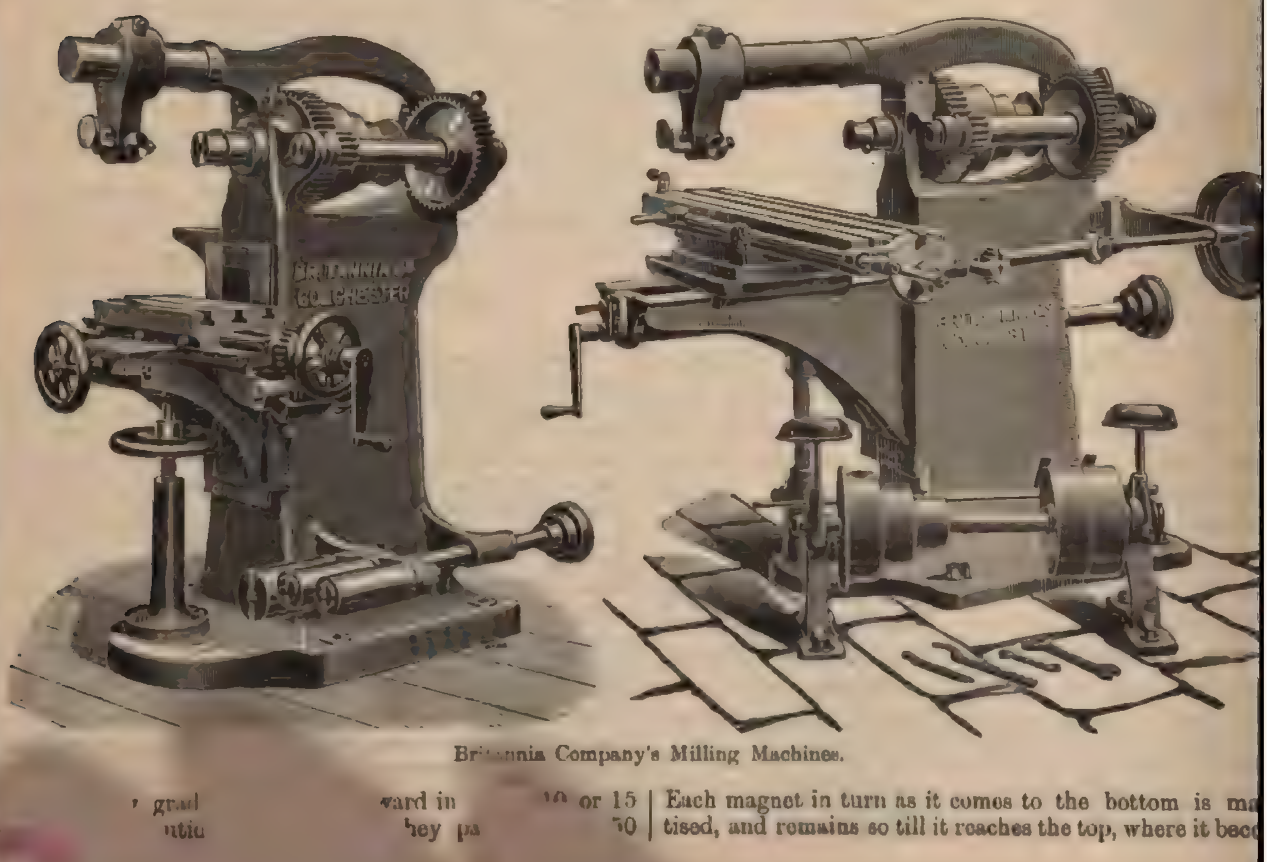
Amongst the machines shown at the recent meeting of the Royal Agricultural Society at Doncaster, referred to in our notice of the show, and entered as a new implement, was the magnetic separator, which we now illustrate. This machine is intended to remove bolts, nuts, nails, horseshoes, etc., from bones, oil cake, or minerals, before they are passed into disintegrating machines, as the presence of these foreign bodies is very detrimental to the machines. The chief difficulties that had to be overcome in designing this machine were the large size and irregular shapes of the material to be treated; the fact also that the iron, particularly in bones, is frequently entangled in the bones, so that merely passing the substance once over or on to a magnet was not found sufficient to ensure the absolutely certain removal of the foreign substance. These points have been satisfactorily overcome by the use of a hollow truncated cone, with 10 internal magnets, of alternately opposite polarity. The cone revolves on outside runners, driven by friction only, which is found ample for the purpose.

Into the back end the bones are fed by a shoot, and, falling to the bottom, are rolled over and over again, so

times over the magnets. In the upper part of the ba[rrel is] a fixed tray into which the iron is carried and coll[ected]



Magnetic Bone Separator.



Britannia Company's Milling Machines.

grad ... ward in ... 10 or 15 ... ntic ... hey pa ... 30

Each magnet in turn as it comes to the bottom is ma[gne]tised, and remains so till it reaches the top, where it bec[omes]

demagnetised, and the iron is detached. This process is carried out by a commutating ring on the back of the machine, and the arrangement is such that each coil has one end permanently connected to one pole of the dynamo, and the other ends are in turn connected during one half a revolution to the other pole. Thus the magnets receive current in parallel. Before cutting a coil out of circuit, it is short-circuited through a resistance, and by this means no sparking of any consequence occurs.

The machine has proved itself a very practical success, and the value of the repeated revolutions over the magnets have been demonstrated by repeated trials. The power required to excite the magnets is about 600 watts for the largest size, capable of dealing with four tons of bones per hour.

The machine was exhibited by the Hardy Patent Pick Company, of Sheffield, makers of the Devil disintegrator, and was manufactured by W. T. Goolden and Co., under the joint patent of Messrs. D. and C. Atkinson and G. W. Elliott.

MILLING MACHINES.

The Britannia Company, of Colchester, recently issued a book upon "Screw-cutting and Milling Machines," which very completely went into the theory and practice of screw cutting of all kinds. Many new types of milling machines were therein illustrated, and we give on opposite page two of the most modern and improved machines, which will not fail to be of interest to electrical engineers.

EXPERIMENTS WITH ALTERNATE CURRENTS OF VERY HIGH FREQUENCY AND THEIR APPLICATION TO METHODS OF ARTIFICIAL ILLUMINATION.*

BY NIKOLA TESLA.

There is no subject more captivating, more worthy of study, than nature. To understand this great mechanism, to discover the forces which are active, and the laws which govern them, is the highest aim of the intellect of man.

Nature has stored up in the universe infinite energy. The eternal recipient and transmitter of this infinite energy is the ether. The recognition of the existence of ether, and of the functions it performs, is one of the most important results of modern scientific research. The mere abandoning of the idea of action at a distance, the assumption of a medium prevadingall space and connecting all gross matter, has freed the minds of thinkers of an ever present doubt,and by opening a new horizon—new and unforeseen possibilities—has given fresh interest to phenomena with which we are familiar of old. It has been a great step towards the understanding of the forces of nature and their multifold manifestations to our senses. It has been for the enlightened student of physics what the understanding of the mechanism of the firearm or of the steam engine was for the barbarian. Phenomena upon which we used to look as wonders baffling explanation we now see in a different light. The spark of an induction coil, the glow of an incandescent lamp, the manifestations of the mechanical forces of currents and magnets, are no longer beyond our grasp. Instead of the incomprehensible, as before, their observation suggests now in our minds a simple mechanism, and although as to its precise nature all is still conjecture, yet we know that the truth cannot be much longer hidden, and instinctively we feel that the understanding is dawning upon us. We still admire these beautiful phenomena, these strange forces, but we are helpless no longer; we can, in a certain measure, explain them, account for them, and we are hopeful of finally succeeding in unravelling the mystery which surrounds them.

In how far we can understand the world around us is the ultimate thought of every student of nature. The coarseness of our senses prevents us from recognising the ulterior construction of matter, and astronomy, this grandest and most positive of natural sciences, can only teach us something that happens, as it were, in our immediate neighbourhood; of the remoter portions of the boundless universe, with its numberless stars and suns, we know nothing. But far beyond the limit of perception of our senses the spirit still can guide us, and so we may hope that even these unknown worlds—infinitely small and great—may in a measure become known to us. Still, even if this knowledge should reach us, the searching mind will find a barrier, perhaps for ever unsurpassable, to the true recognition of that which seems to be, the mere appearance of which is the only and slender basis of all our philosophy.

Of all the forms of nature's immeasurable, all-pervading energy, which, ever and ever changing and moving, like a soul animates the inert universe, those of electricity and magnetism are perhaps the most fascinating. The effects of gravitation, of heat and light we observe daily, and soon we get accustomed to them, and soon they lose for us the character of the marvellous and wonderful; but electricity and magnetism, with their singular relationship, with their seemingly dual character, unique among the forces in nature, with their phenomena of attractions, repulsions and rotations, strange manifestations of mysterious agents, stimulate and excite the mind to thought and research. What is electricity? and What is magnetism? These questions have been asked again and again. The most able intellects have ceaselessly wrestled with the problem; still the question has not as yet been fully answered. But while we cannot even to-day state what these singular forces are, yet we have made good headway towards the solution of the problem. We are now confident that electric and magnetic phenomena are attributable to ether, and we are perhaps justified in saying that the effects of static electricity are effects of ether under strain, and those of dynamic electricity and electromagetism effects of ether in motion. But this still leaves the question, as to what electricity and magnetism are, unanswered.

First, we naturally enquire, What is electricity, and is there such a thing as electricity? In interpreting electric phenomena, we may speak of electricity or of an electric condition, state or effect. If we speak of electric effects, we must distinguish two such effects, opposite in character and neutralising each other, as observation shows that two such opposite effects exist. This is unavoidable, for in a medium of the properties of ether we cannot possibly exert a strain, or produce a displacement or motion of any kind, without causing in the surrounding medium an equivalent and opposite effect. But if we speak of electricity, meaning a thing, we must, I think, abandon the idea of two electricities, as the existence of two such things is highly improbable. For how can we imagine that there should be two things, equivalent in amount, alike in their properties, but of opposite character, both clinging to matter, both attracting and completely neutralising each other? Such an assumption, though suggested by many phenomena, though most convenient for explaining them, has little to commend it. If there is such a thing as electricity, there can be only one such thing, and, excess and want of that one thing, possibly; but more probably its connection determines the positive and negative character. The old theory of Franklin, though falling short in some respect, is, from a certain point of view, after all, the most plausible one. Still, in spite of this, the theory of the two electricities is generally accepted, as it apparently explains electric phenomena in a more satisfactory manner. But a theory which better explains the facts is not necessarily true. Ingenious minds will invent theories to suit observation, and almost every independent thinker has his own views on the subject.

It is not with the object of advancing an opinion, but with the desire of acquainting you better with some of the results, which I will describe, to show you the reasoning I have followed, the departures I have made—that I venture to express, in a few words, the views and convictions which have led me to these results.

I adhere to the idea that there is a thing which we have been in the habit of calling electricity. The question is, What is that thing? or, What, of all things, the existence of which we know, have we the best reason to call elec-

* Lecture delivered before the American Institute of Electrical Engineers at Columbia College, New York, May 20.

tricity? We know that it acts like an incompressible fluid; that there must be a constant quantity of it in nature; that it can be neither produced nor destroyed; and, what is more important, the electromagnetic theory of light and all facts observed teach us that electric and ether phenomena are identical. The idea at once suggests itself, therefore, that electricity might be called ether. In fact, this view has in a certain sense been advanced by Dr. Lodge. His interesting work has been read by everyone, and many have been convinced by his arguments. His great ability, and the interesting nature of the subject, keep the reader spellbound; but when the impressions fade, one realises that he has to deal only with ingenious explanations. I must confess that I cannot believe in two electricities, much less in a doubly constituted ether. The puzzling behaviour of the ether as a solid to waves of light and heat, and as a fluid to the motion of bodies through it, is certainly explained in the most natural and satisfactory manner by assuming it to be in motion, as Sir William Thomson has suggested; but, regardless of this, there is nothing which would enable us to conclude with certainty that, while a fluid is not capable of transmitting transverse vibrations of a few hundred or thousand per second, it might not be capable of transmitting such vibrations when they range into hundreds of million millions per second. Nor can anyone prove that there are transverse ether waves emitted from an alternate-current machine, giving a small number of alternations per second; to such slow disturbances, the ether, if at rest, may behave as a true fluid.

Returning to the subject, and bearing in mind that the existence of two electricities is, to say the least, highly improbable, we must remember that we have no evidence of electricity, nor can we hope to get it, unless gross matter is present. Electricity, therefore, cannot be called ether in the broad sense of the term: but nothing would seem to stand in the way of calling electricity ether associated with matter, or bound ether; or, in other words, that the so-called static charge of the molecule is ether associated in some way with the molecule. Looking at it in that light, we would be justified in saying that electricity is concerned in all molecular actions.

Now, precisely what the ether surrounding the molecules is, wherein it differs from ether in general, can only be conjectured. It cannot differ in density, ether being incompressible; it must, therefore, be under some strain or in motion, and the latter is the most probable. To understand its functions, it would be necessary to have an exact idea of the physical construction of matter, of which, of course, we can only form a mental picture.

(To be continued.)

THE ELECTRIC TRANSMISSION OF POWER.*

BY GISBERT KAPP.

LECTURE I. *(Concluded from page 42.)*

I need hardly say that, at the present time, no English millowner would dream of working his mill in this fashion by animal power, since coal is yet abundant, and a single steam engine is a far cheaper and handier instrument for producing and controlling a large amount of power than an equivalent number of horses. On the other hand, if power is required in small quantities, and in particular ways, then the horse will produce this power better, more cheaply, and more conveniently than the steam engine. It may seem absurd to work a large cotton mill by horse gear; but substitute for the mill a farm, and you see at once that the transmission of stored power to it, in the shape of corn, is a necessary part of the agricultural operations. Now the horses, in bringing the corn to the place where the power is required, perform work and must consume an equivalent amount of food. They also perform work in bringing the empty carts back again to the field to be recharged. The ratio between the amount of corn delivered at the mill and the amount taken out of the field would therefore represent the efficiency of transmission. If this is to be 90 per cent., as is the case of electric transmission, we may take it that, for every 100 sacks of corn taken away from the field, the horses would eat on the outward journey (when the carts are heavily laden) 6½ sacks, and on the homeward journey (when they are empty) 3½ sacks, leaving 90 sacks of corn to be converted into live power at the mill. The distance to which we can thus carry stored power with a standard efficiency of transmission is a measure of the merit of the system, as far as economy of power is concerned.

The transmission of stored power in the shape of fuel is a parallel case. We load the coal at the pit's mouth into waggons and haul them by means of locomotive engines to the place where the power is wanted. Part of the coal is consumed on the outward and homeward journey of the train, leaving the rest for the production of live power at the mill. If this amounts to 90 tons out of every 100 tons put on the train at the pit's mouth, we have again an efficiency of transmission of 90 per cent.

I have already mentioned that the exact distance to which we can carry power by either of the three agents here mentioned—namely, batteries, corn, and coal—depends very much on the kind of road over which the transmission takes place. We might assume an almost infinite variety of cases, but, as our object is to obtain a rough general comparison of the different systems rather than exact figures for any one of them, I have assumed merely three kinds of roads—namely, a common carriage road, a tramway, and railway—and have calculated the distance to which power can be transmitted in each case with a loss of 10 per cent. The results of these calculations are given in the following table. The speed of transmission has been assumed at four, six, and 20 miles for road, tram, and rail respectively, when coal or batteries are the transmitting agents, and at four miles on all kinds of road when corn is the transmitting agent. In all cases I have assumed that the road is the best of its kind, perfectly free from gradients or curves, and that the traffic can be worked at the speeds mentioned without interruption. In reality, these conditions will, of course, not all be fulfilled; we have to make allowances for waste of power on gradients, curves, bad places in the road, for running at variable speed, and for stopping and starting. The distances given in the table are, therefore, throughout too large; but as our purpose is merely the comparison of the different systems, we may take the figures in the table as a rough indication of the merits of each. The figures show the distance in miles attainable with 90 per cent. efficiency of transmission over road, tram, and rail:

TRANSMISSION OF STORED POWER.

Source of power.	Road.	Tram.	Rail.
Coal and steam engine	115	270	1,3[illegible]
Corn and horse	52	170	44[illegible]
Storage battery and electromotor	4	10	[illegible]

You will see, from this table, that as regards efficiency the electric transmission of stored power cannot compete with the other two methods. A horse and cart carrying corn over an ordinary carriage road works with twice the efficiency of the electric locomotive taking batteries over a railway. The discrepancy is still greater if we compare the electric locomotive hauling batteries with the steam locomotive hauling coal. The latter can transmit power over a distance 50 times that over which the former can transmit power with an equal efficiency. On a tram line the distance over which we can transmit power with an efficiency of 90 per cent. is, according to the table, 10 miles—that is to say, if the whole load of the car is composed of batteries, we can run it 10 miles out and 10 miles home at an expenditure of 10 per cent. of the total charge of the batteries. Now let us see how this compares with the storage cars in use on passenger tram lines. The total weight of a full-sized car is about 10 tons, made up somewhat as follows: car and propelling gear, 4 tons; batteries, 2½ tons; passengers, 3½ tons. If the 3½ tons represented by the passengers were utilised for additional storage cells, the car could run 20 miles with the loss of 10 per cent. of its charge; or it could run 200 miles if losing the whole of its charge. As there are, however, only 2½ tons of batteries instead of six tons, it can only run 86 miles. This is according to the table, and more than attainable in practice, for the reasons already stated. Experience has shown that storage cars can only run from 30 to 60 miles with one set of batteries, or half the distance stated in the table. If we apply the same reduction to all the methods of transmission, we find that the distances to which power can be carried electrically in the stored form, with an efficiency of 90 per cent., are two, five, and 18 miles over a carriage road, tramway, and railway respectively.

The efficiency of transmission is, however, not the only or even the most important consideration in the problem of transmitting power to a distance. The owner of a transmission plant cares nothing for any theoretical perfection in the way of high efficiency. All he cares for is the cost at which the power is delivered to him. All other things being equal, high efficiency will naturally reduce this cost, and in so far is an advantage, but in practice all other things are not equal, and to aim at high efficiency regardless of other considerations is the reverse of good engineering. It is no doubt gratifying to the engineer if he can point to a transmission plant designed by him to give some extraordinarily high efficiency, but if this result has been obtained by means of an exorbitant capital outlay and excessive working expenses, it will not be equally gratifying to his employer, the owner of the installation, who has to pay for its erection and working. It therefore becomes the duty of the engineer so to

* *Cantor* lectures delivered before the Society of Arts.

plan the installation that the cost of the power delivered shall be a minimum under any given circumstances.

We have seen that, as judged by the efficiency standard alone, electric transmission of power in the stored form is hopelessly behind the other two methods which we compared with it. Let us now see whether this is or is not the case if we judge the system by the more practical, and, indeed, the only reliable test of cost. It is of course understood that in estimating the annual cost at so many pounds per horse-power delivered, we take into account not only the cost of coal burnt throughout the year, if we obtain the power by steam, or the rent for water, if we use a turbine, but also all other expenses which may properly be charged to the power account, such as wages for the attendants, petty stores, interest, repairs, and depreciation of plant. Estimated in this way, the cost of water power will be found to vary between £2 and £8 per annum, the exact figure depending, of course, on the total amount of power available, the quantity of water, its fall and local conditions, which must largely influence the cost of the hydraulic works. The cases where water power can be had at so low a price as £2 a year are exceptional; on the other hand, if we have to pay as much as £8 a year for water power, it will seldom be worth while to transmit it electrically, or in any other way; and I shall therefore assume £3 and £6 as the limits of cost for water power intended for electric transmission. The cost of steam power, if produced by large economical engines, is generally taken at £10 per year; if produced by small, and therefore less economical engines, it may rise to £20, and even £40 per year. I shall further assume that in all cases the power is required for 3,000 hours during the year—that is, 300 work days of 10 hours. At the outset it is clear that if we wish to transmit large parcels of power—say, 100 h.p. and upwards by storage batteries, we must be able to deliver the power at a cost not exceeding £10 a year; for were the cost higher, it would obviously pay better to establish a local steam engine. I have already mentioned that a system of battery transmission can be made to yield 56 per cent. efficiency, if we allow 10 per cent. for the transmission itself. To deliver 100 h.p. we must, therefore, charge with 178 h.p. during a time equal to that during which the power is required. If, therefore, at the generating station the annual horse-power costs £3, the charge for power alone will be £5. 6s. at the receiving station. To this must be added the cost of labour and the interest and depreciation of plant, which, in this case, consists of the generating dynamo, motor, batteries, and line of transmission, with its equipment of locomotives and waggons. The small storage cells, as now made, for lighting and power purposes, cost about £40 per horse-power; but let us assume that the larger cells, such as we would require, could be had for £30 per horse-power, then a battery to work a 100-h.p. motor would cost £3,330. In order to economise carriage, and to reduce the wear and tear of cells, it would be advantageous to have two batteries, one being charged while the other is at work. We have thus an initial outlay of £6,660 for batteries alone. The interest and depreciation on these will certainly not be less than 15 per cent., or £10 per horse-power. Add to this the cost of power at the generating station, that of labour and interest and depreciation on the electric machinery and the line, and you will see that it is quite impossible to compete with battery transmission against a local steam engine, if the power produced by the latter costs £10 per annum. But how does the case stand, if the amount of power required is so small that it cannot be produced at this low figure. If we want only 5 h.p., and if we produce it by a local steam or gas engine, we shall have to pay for each horse-power £20 to £40 per annum. Will it in this case pay to transmit by means of batteries the power produced by a large and economical steam engine at some central station? If we have to build a tramway or railway for this purpose specially, it will certainly not pay; but let us assume that a tramway already exists, and let us investigate whether the company, which we suppose is working the line by storage cars, could afford to sell to a customer on the line power at a cheaper rate than he could produce by a local engine. Let us assume, by way of example, that the customer requires 5 h.p. for 10 hours daily. The battery to work a 5-h.p. motor will weigh about 2½ tons, and cost £170. The charging dynamo, motor, and regulating gear will cost about £150, so that the whole capital outlay, if we provide two batteries, will amount to £490.

Now let us see how such a system of transmission will have to be worked, and what the working expenses will be. I take, by way of example, five miles as the distance between the generating station, which may be the tramway depot or a central electric light station on the line of tramway, and the delivery station. At either terminus we must have mechanical appliances for loading and unloading the batteries from the car, such as are generally used in connection with storage cars. Early in the morning a charged battery is put on the car, and run out to the delivery station, where it is unloaded and connected to the motor. The other battery which has served during the previous day, is loaded on the car and taken back to the depot to be charged up again. In this manner the car need only make one journey out and one journey home daily. As its speed may be very moderate, say from three to four miles an hour, the cost of running this car will be much less than that of a passenger car, which must stop and start every few minutes, and run at a higher speed. I take 3d. per car mile as the cost of haulage, including the use of plant, and I further allow 2s. a day for labour in loading and unloading the batteries. The account of working expenses will now stand somewhat as follows:

Power at generating station at £10, allowing 65 per cent. total efficiency*	£77	0	0
Haulage	37	10	0
Labour	30	0	0
15 per cent. interest and depreciation on batteries (340)	51	0	
10 per cent. interest and depreciation on electric machinery (£150)	15	0	0
Total annual cost	£210	10	0

This works out at £42. 2s. per annum per horse-power delivered, and is therefore quite as high, if not higher, than the cost of power obtained by a small and uneconomical local engine. On the score of economy there is consequently no advantage in transmitting power by storage batteries in the present case, where the distance of transmission is five miles. Had the distance been less, the working expenses would also have come out smaller, but not by any considerable amount. The only item in which we could save is cost of haulage, and if we neglect this altogether we have still to pay £34s. 12s. per annual horse-power delivered. Battery transmission can therefore not compete against power produced by a local engine, even if the latter be of the rather uneconomical type which users of small power still tolerate. But how stands the case if for some local reason the employment of a heat engine of any kind is precluded? We have then the choice between electric transmission by means of batteries, and directly by means of a pair of wires. Which will be the more economical? As the dynamo and motor, except, perhaps, in the matter of voltage, will be the same in either case, the answer to this question turns upon the comparison of the batteries and line of wires. The first question to consider is whether our wires may in the case of direct transmission be carried overhead on poles and insulators, or must be put underground. If the former be the case, the line need not cost more than £130 per mile; and I may at once mention that from the experience gained with various power transmissions, which I hope to bring before you, this item can be estimated with a fair degree of accuracy. As I shall have to deal more in detail with the cost and construction of live power transmission plants later on, I shall not enter into details at present, and must ask you to take my statements as to cost of line and cost of power transmitted as correct, though I do not now show how the account is made up. As regards transmission by wires placed underground, there is, as far as I know, no example of such an installation, and we can therefore not verify our estimate by reference to work actually executed, as we can in the case of overhead transmission. We are thus forced to calculate the cost of the line according to the data obtainable for electric light mains, and I take for this purpose an estimate made by Mr. Crompton in his paper on "Central Station Lighting," read before the Institution of Electrical Engineers on the 12th of April, 1888. In this paper Mr. Crompton gave tables for the cost of underground mains of various types and sizes, and by reference to his tables I find that a main of the section required for the transmission of 5 h.p., and insulated so as to safely bear a pressure of 1,000 volts, would cost about £670 per mile. We have now all the necessary particulars for making a comparison of the cost of transmission and direct transmission, the latter by both overhead and underground wires. The following table gives the result. The cost includes the charge for power at the generating station (taken at £10 per annual horse-power), and interest and depreciation on the plant, which is taken at 15 per cent. for the batteries, and 10 per cent. for the line and electrical machinery.

TRANSMISSION PLANT FOR 5 H.P.

Distance of transmission in miles.	Annual cost per horse-power delivered, if the transmission is		
	By batteries.	Direct.	
		Overhead.	Underground.
	£	£	£
1	36·1	22·8	33·6
2	37·6	25·6	47·2
3	39·1	28	60
4	40·6	30·6	74
5	42·1	33	87

* In this case the efficiency is the ratio of the power supplied to the charging dynamo to that obtained from the motor, and does not include power spent in transmission, being charged for in the account at 3d. per car mile.

We see from this table that if there is no objection to an overhead line, the electric transmission of stored power by means of batteries cannot compete against the direct transmission of live power by means of a pair of wires, even if the distance is considerable. But in towns we cannot have, or at least we ought not to tolerate, overhead lines, and if we work with an underground line we find that, for distances exceeding one mile, the battery is a more economical transmitting agent than the wire. Here we have at last found a case where it will be advantageous to transmit power by means of storage batteries, but there are so many conditions attached to the case that the field of application of such a system must necessarily remain very limited. First, the power must be required, so to say, in small parcels; secondly, there must be a tram line handy, and the customers must have facilities for loading and unloading the batteries and accommodating them on his premises; thirdly, there must be a charging station on the line having similar facilities; fourthly, the use of an overhead line must be excluded; fifthly, the distance must exceed one mile; and, finally, there must be some reason why a local engine cannot be used. I need hardly point out that a system of transmission fenced in by so many conditions cannot have any commercial importance. Thus far, the result of our investigation is entirely negative. We find that transmission of power by means of storage batteries, whether the power transmitted be large or small, is not so economical as other methods of transmission, and has, therefore, no commercial value for all cases where these other methods are applicable. If I have, nevertheless, devoted some part of this lecture to the subject of battery transmission, it was because the idea of distributing power, so to speak, bottled up in batteries, seems to have a fatal charm for many inventors. It is an old idea, but is always coming up again, and for this reason I thought it advisable to go a little into figures and show you how the case really stands. It might, perhaps, be objected that as no distribution of stored power by means of ambulant batteries has as yet been practically introduced, it is premature to give an opinion as to the possibilities of such a system. The idea of battery distribution of power is, as a matter of fact, entertained not only by amateur electricians, but also by practical engineers. As an example of this fact, I may quote a passage in a report written about two years ago by Mr. J. F. Fanning. This gentleman, reporting to the Cataract Construction Company on the question of utilising the power of Niagara Falls, says: "Power and lighting currents may be electrically transmitted to neighbouring cities, and possibly storage batteries may be electrically charged and recharged, and many times forwarded for use in surrounding cities." When writing this, Mr. Fanning had, of course, in view cheap water power, and probably canal transportation. If, at the same time, batteries could be made cheaper, lighter, and more durable than they actually are at present, then, but not until then, will they become commercially possible as transmitting agents in competition with other systems of power transmission. Taking batteries as we find them at present, their use as agents in the transmission of power is only justifiable in cases where the direct transmission by means of conductors cannot be employed; and this brings me to the consideration of the only case of the electric transmission of stored power which, as yet, has attained to practical importance—namely, the use of batteries for locomotive purposes.

Although electric tramcars come, strictly speaking, within the title of my lectures, I do not propose to consider them at any length, the reason being that this branch of power transmission alone, if treated in detail, would absorb all the time at my disposal. I shall, therefore, content myself in taking up the subject only so far as is necessary to show in a general way what is the present practice in this branch of power transmission.

We have in this country two very good examples of battery tramcars, the one being the cars now running in Birmingham, and the other the cars on the Barking-road line in the north of London. Of the former I have not been able to obtain much information, but of the latter I have, by the kindness of Mr. T. Fraser, who superintended the erection and working of the plant, been able to obtain all the information required for my purpose. I am also indebted to Mr. Reckenzaun for information regarding his cars, which are in use at Philadelphia. The accompanying table gives the principal data of these cars conveniently arranged for comparison and reference.

Taking the averages of the last two lines in the table, we find that for a car representing a total rolling weight of 10 tons, we require a battery capable of giving a maximum output at its terminals of 19 e.h.p., and a mean output of 5·6 e.h.p. It must, however, be noted that the latter figure applies to the time the car is actually in motion, and does not include the power wasted in starting. Mr. Fraser has made very careful observations of the power flowing out of the batteries during the whole of the time the car is in service, and found that the integrated power divided by time comes to 7·33 e.h.p.; that is say, a motor taking from the batteries all day long 7·33 e.h.p., will take from the batteries the same amount of power that is actually taken under the intermittent work going on in the running of a tramcar. Of the 7·33 e.h.p., a good motor will yield about 6½ b.h.p. Taking the efficiency of the batteries at 60 per cent., a figure by no means too low when we consider the very irregular nature of the work done by these batteries when in service, we find that the electrical horse-power of the charging dynamos required per car is about 12 e.h.p. The ratio between the indicated power of the engine and the output of the charging dynamo may be taken at 80 per cent., so that we shall have to provide engine power at the rate of 15 i.h.p. for every car, provided the engines are worked for the same number of hours that the cars are in service. If the engines are worked for a longer time, say by night as well as by day, a corresponding reduction in the total indicated power of the station can of course be made.

STORAGE BATTERY TRAMCARS.

—	Birmingham.	Barking-road.	Philadelphia. Small car.	Philadelphia. Large car.

Average energy per 10 tons of rolling weight (electrical horse-power).........	—	5·65	6·42	4·95

Returning now to the subject of the cost at which stored power can be retailed by electric transmission to small consumers, let us briefly glance at the rival system—namely, the distribution of small parcels of live power from a central electric light station. One hears it often stated that the supply of power, and not that of light, must become the chief business of such stations. The argument in support of this view is somewhat as follows: The demand for light is very uneven, being less than a tenth of the capacity of the station for many hours during the day, and rising very rapidly towards evening. The period of large demand comprises only a few hours, and during that time the engines work with great economy. During the remainder of the day the economy is less; and, in fact, the greater portion of the coal bill, cost of attendance, and interest on the capital outlay is chargeable to light running. If, therefore, by the sale of power, we could keep the central station plant economically working during the whole of the day, the increase in the working expenses would be slight, but the increase of revenue would be very considerable. This argument is perfectly sound, but it has the rather serious defect that it will not convince the very people from whom this large increase of revenue is to be obtained; for, let us see what it means to the user of power. As you know, electric current is supplied from central stations, at a charge varying from 4½d. to 8d., and even 1s. per Board of Trade unit. The usual charge in London is about 7d. Now, suppose a small manufacturer, requiring only a few horse-power, determines to discard his small steam or gas engine, and put up an electromotor, to be worked by current from a central station, what will the power cost him? This, of course, depends on the time—that is, the number of hours in the year during which he requires power. If he has a small factory, in which work is steadily going on day by day, you may estimate that the power will be required during 3,000 hours per annum. It is now very easy to calculate the annual cost of each brake horse-power. Allowing £1. 10s. per horse-power for depreciation and interest on the motor, and £1 for petty stores, we find that, at 7d. per unit, the annual horse-power comes to £75. With current at a different price, the cost of power will be accordingly altered, as shown in the table:

POWER DERIVED FROM A CENTRAL STATION.

Cost of Board of Trade unit	d. 1	d. 2	d. 3	d. 4	d. 5	d. 6	d. 7	d. 8
Cost of annual brake horse-power for 3,000 hours ...	£ 12·9	£ 23·3	£ 33·5	£ 43·9	£ 54·2	£ 64·5	£ 75	£ 85·4

It is clear from this table that the small user of power will

only use an electromotor if he can get current at about 3d. per unit, and, unless electric light companies can supply at this price (which at the present time does not seem likely) there is no prospect of supplying electric power to small factories wanting the power continuously. Another disadvantage is that the demand for power must, in winter at any rate, overlap the demand for light, thus requiring the erection of additional plant. If, however, the power is only required intermittently, then the electromotor is by far the cheapest instrument for producing it, not only as regards first cost, but also as regards working expenses. There are many small trades in which power is wanted only for a few hours during the day. If, for instance, the actual running time of a lathe is two hours daily, then the cost of the annual horse-power, with current at 7d., would only be £15, a figure which cannot be touched by either steam or gas. There is the further advantage of having the power always ready. There is no need to get up steam, look to the feed pump, open cylinder cocks, turn the engine over the centre, and generally do the dozen little things which are required in starting an engine. With a motor, all that is required is to turn on the switch when the power is wanted, and to turn it off again when the job is done. For domestic purposes, again, nothing could be more handy and economical than electric power supplied from a central station. I have here a collection of appliances, for the loan of which I have to thank the Keys' Electric Company, and I can show you how easy and convenient it is to apply electric power to small domestic machinery.

I have in the present lecture dealt with what may be termed general questions of engineering policy rather than with technical details, and I am afraid you will have found the financial parts of the lecture rather a dry subject. The question of cost is, however, of the utmost importance in engineering work, and it was therefore necessary to give it some consideration. In the remaining two lectures I shall be able to turn to the more interesting parts of our subject, and bring before you some of the scientific principles and technical details relating to the electric transmission of live power over long and short distances.

ELECTRIC TRAMWAYS.

Some time since Mr. Frederick Brown, A.I.E.E., was requested to report to the Walsall Corporation on electric traction. Mr. Brown visited America, and carefully examined into the equipment and working of many of the tramways, and upon his return reported to the Corporation. After referring to the various lines inspected, he sums up his conclusions in the following manner:

There are three styles of carrying the overhead wire, which is known as the trolley wire.

1st. Where there are two lines of rails, centre poles are used with an arm on each side carrying the wire. These would not be suitable for our streets and roads; though in wide roads they do not look very bad. In our roads they would be in the way, and a dangerous obstruction.

2nd. Where the tram lines are laid at the side of the road or street, poles with an arm are used, carrying the trolley wires over the centre of the track.

3rd. Lighter poles are erected on each side of the street, and a wire called a span wire (which is not used for conveying electricity, but only as a means of support) is stretched across, and the electric or trolley wire is hung from that over the centre of the track. This is by far the most convenient: and in the American roads, where trees are planted on each side, is the least unsightly, and is, all things considered, I think the most suitable for use here, as our streets vary in width, thus varying the distances from the rail to the kerb, which would, if the second plan named above be used, necessitate the arms on the poles varying in length, which I fear would look very unsightly. At junctions and corners there is some complication, which is certainly no ornament to the streets, but it is entirely a matter of opinion. I find that the public in America prefer the eyesore of the wires to horse or steam power; the noise and smoke of the latter they much object to.

I submit various photographs for your inspection, and am expecting others.

Other wires than the trolley wire are necessary for bringing the power to the various sections of the trolley wire. These are called feeders, and are carried on insulators attached to the poles that carry the span wires.

In important streets I should advise these being put underground, but outside the centre of the town they might be run as is usual in America.

The speed of the cars is regulated by the city authorities, and varies on different roads from six to 12 miles per hour, though the latter is often much exceeded outside the cities.

The electric cars are safer than the ordinary cable car, as they can be run in either direction at will, and so can back out of danger if necessary, and the danger of the grip getting caught in a broken strand of a cable, and so the driver losing the power of stopping, is avoided.

The speed can be varied at will, from a crawl to 30 or more miles per hour. There is complete absence of jerk in starting, the suddenness of the stop of course being in the hands of the driver, who can, if necessary, stop within a car's length when going at full speed.

At first there was some trouble with joints in the trolley wire giving way, but this appears to be a thing of the past, as improved means of jointing have been introduced.

Much of the overhead work in America has been done in a hurried manner, and could be made much neater and safer with more care and time being spent upon it. This point should be insisted upon if the system be allowed here.

I found no complaint from interruption to ordinary traffic from the wires, they being high enough for all loads to pass under, excepting some special cars belonging to a circus, the wires preventing the emblematic characters from riding on the top.

In America the wires are carried about 19ft. from the ground. They should be rather higher here to allow of our fire escape passing under. The American escapes are carried horizontally.

In cases of fire the firemen cut the wires down if necessary, the current being cut off from that section—telephones being fixed in the power stations for the purpose of giving notice, or a system of electric signals is used.

I have, for your inspection, a number of reports from various bodies on the subject, among which you will find letters from a number of mayors of cities in which overhead wires are in use.

In reply to the points on which you requested me to obtain special information I beg to state:

1st. Duplicate lines of rails are not necessary unless required by the traffic.
2nd. The existing lines of rail will need some alteration—viz., each rail needs connecting to the next by a strong copper wire riveted into each, and they also need electrical connection across. Earth-plates should also be put in at times, as it tends to lessen the action on the telephone.
3rd. Posts may be on one or both sides of the road.
4th. The posts are not complained of.
5th. The posts are about 40 yards, or 120ft., apart.
6th. The posts can be used for carrying other wires and for carrying electric lamps, and could be used for sewer ventilation.
7th. The roads are mostly lighted by electricity, some with gas, and some with oil.
8th. The poles are to be so fixed as to be safe, and the wires to be not less than 19ft. high.
9th. No special rule as to distances from kerb. The narrowest street I saw was 20ft. 6in wide, and it had a 4ft. 6in. track in centre. This street had two tracks in it, but the tram people altered it, as it delayed their traffic, the cars not being able to pass a standing cart or waggon.
10th. The arms project to centre of track.
11th. No objection is raised excepting by circus proprietors.
12th. Horses seem to take no notice. I only saw one case of restiveness.
13th. Cars work either way, and do not need to be turned.
14th. A bell has to be rung on nearing a cross road, and head lights are carried. The driver rings the bell with his foot, thus leaving both hands for the brakes if necessary.
15th. The cars passing each other, or passing a crossing, must always sound a bell.
16th. Authorities limit the speed from six to 12 or more miles per hour. The driver has complete control.
17th. I heard of no complaints, though at times they have them from what they term the abutters—i.e., persons whose property abuts upon the street in which the lines of rail are laid.
18th The width of pavement varies so much that I can give no measurements.
19th. The wires are mostly carried overhead—some are underground.
20th. The wire is fixed to an insulator at the terminus, and is above the heads of the public.
21st. There is no danger to human life.
22nd. The posts vary in thickness and material, some being wood, some iron tube, and some lattice work in iron; the base being about 6in. to 8in.
23rd. Unless the improved motors are used the noise is objectionable. With the improved motors and gear I heard of complaint of their not making noise enough.
24th. There is at times a little sparking visible which might frighten a horse, but I failed to hear of a case, and as our roads are better than the American, this flashing would be reduced.
25th. The narrowest road I saw was about 20ft. 6in. The widest was 120ft.
26th. There are streets where telegraph, telephone, and electric light wire posts are fixed, with the poles for the cars. They are fixed any how that seemed best to the men who put them up, and want some regulations in this respect.
27th. Sign-boards and other projections have been allowed, but are being removed pretty fast by the authorities, though many remain.
28th. There are from one to six lines on some of the poles.
29th. The tramways are worked by private companies and not by the authorities.
30th. I found no case in which the authorities had any right to use the tramways for public purposes without paying for such use.
31st. Their fire escapes are run horizontally and they have no trouble, though if a wire is in the way they cut it down.
32nd. The maximum potential is in use now, and the usual one is 500 volts.

I may state, in conclusion, that the use of the system is muc increasing, there being on order in the works that I visited some 2,000 motors.

REPORT ON INSPECTION AND TESTS OF BROWN'S PATENT ROTARY EXPANSIVE ENGINE.

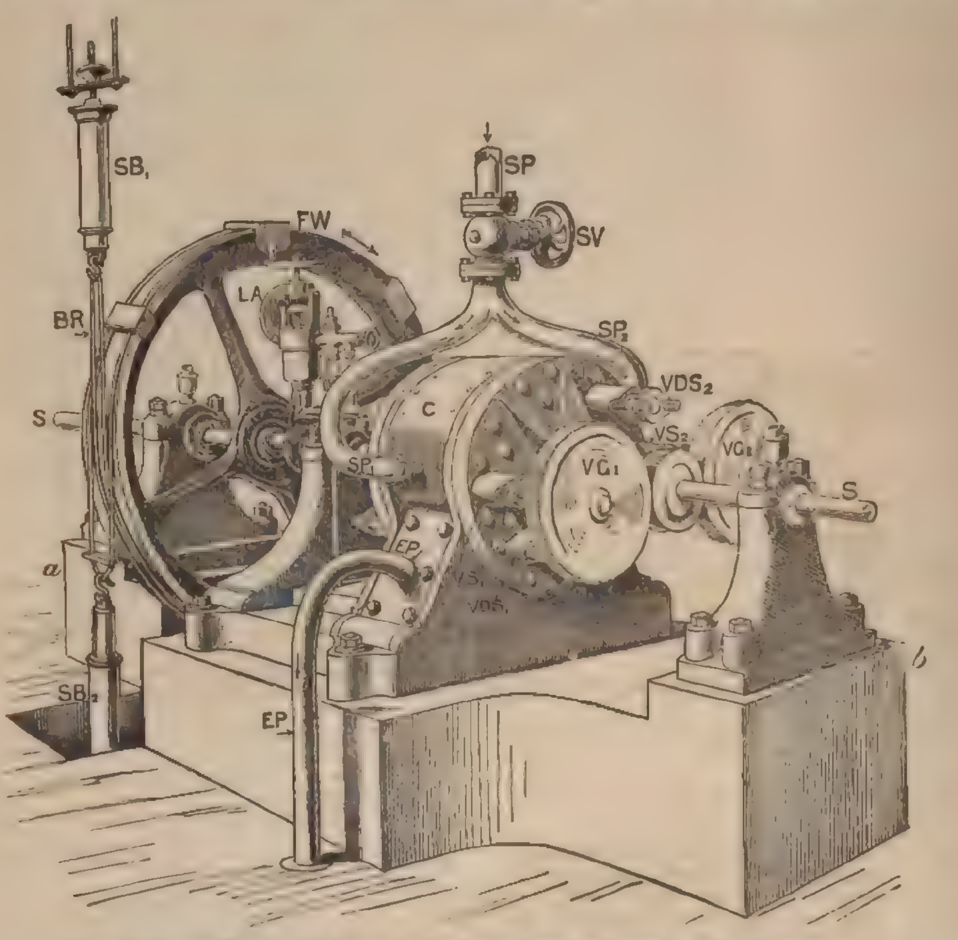
BY PROF. JAMIESON, M.I.C.E., F.R.S.E., ETC.

The following is the expert's report to the makers upon this engine :

Having been requested by you to test and report upon your latest improved rotary engine, I went to Messrs. Lang and Son's tool works, Johnstone, on the morning of Wednesday last, the 27th May, with two assistants, where I found the boiler, engine, and all the necessary instruments in perfect order.

General Description of Engine and Brake Gear.—Before giving the details of my tests I will describe briefly the general features of your engine and the brake gear adopted by aid of the accompanying photo-lithograph from a freehand sketch made by Mr. J. H. Oswald Brown, artist, on June 4th, prior to my taking the second set of indicator cards.

Details of Cylinder and Valves.—The chief points of novelty about your engine are the cylinder, piston, and valves. The cylinder is only 10·5in. diameter by 8·625in. in length, or 746·9 cubic inches. The cross area of the piston is 40·5 square inches, and its length is 8·625in., or 349·3 cubic inches, so that it occupies nearly one-half of the volume of the cylinder.



Brown's Rotary Expansive Engine with Brake Gear, as Tested by Prof. Jamieson.

S P, steam-pipe from the locomotive boiler ; S V, stop valve ; S P_1, S P_2, steam-pipes branching to each rotating steam admission valve ; C, cylinder ; V G_1, V G_2, valve gearing for working the steam admission valve ; V S_1, V S_2, valve spindles to which V G_1, V G_2 are keyed ; V D S_1, V D S_2, (oscillating) valve door spindles ; E P, exhaust pipe ; L A, lubricating apparatus ; S, S, shaft to which piston, etc., are keyed ; F W, flywheel, 4ft. diameter, specially fitted for taking the B.H.P. of the engine ; B R, brake ropes ; S B_1, S B_2, Salter's (spring) balances.

The cylinder receives steam twice during each revolution of the piston from two cylindrical rotating valves fixed to the valve spindles, V S_1, V S_2, which are placed diametrically opposite to each other, and respectively between the steam pipes, S P_1, S P_2, and the cylinder valve doors. The valve spindles are driven by the valve gearing, V G_1, V G_2, from a pinion keyed to the central shaft, S. They can be adjusted so as to cut off the steam at any desired point of the piston's revolution, or they may be connected to a governor so as to maintain a uniform speed under widely different variations of load and steam pressure.

Two oscillating valve-doors, keyed to the spindles, V D S_1, V D S_2, form part of the circumferential working surface of the cylinder when they are closed. They are alternately opened by the incoming steam pressing behind them whenever the peculiarly shaped piston has passed them, and owing to your effective mode of cushioning the steam between them and the rotating valves, they are closed gently by the piston during the time of exhaust. The front edges of the valve-doors form a continuous steam tight joint with the rotating piston in such a manner that the reaction due to the steam pressure between their back faces and the effective area of the piston causes the latter to revolve. The higher the piston speed, the greater is the economy of steam. The steam, after being cut off by the rotating valves, expands, doing work until it exhausts through the axle bosses of the oscillating valve-doors.

Preliminary Inspection and Verification of Apparatus.—I carefully measured the volume of the boiler water supply tank, and found it to be 305lb. for every barrel full, checked the brake spring balances by Government stamped standard weights, saw that the brake ropes were properly adjusted, and found the radius of the brake load, r, to be 2·0417ft., which gave the logarithm of the constant, etc., for brake horse-power $\left(\log \frac{2\pi r}{33,000}\right) = \bar{4}\cdot5895$.

log. of constant .. .. $= \bar{4}\cdot5895$
log. of mean brake pull, 93·2lb. $= 1\cdot9694$
log. of mean speed, 574·5..... ... $= 2\cdot7593$

log. of mean B.H.P., 20 8 ...... $= 1\cdot3182$

Trial Run, Periodical Observations.—With steam shut off from the engine, the feed-water was forced into your locomotive multi tubular boiler by the injector, until it reached a definite mark (about half glass) on the polished brass scale, fixed immediately behind the gauge glass. The water supply tank was then filled up to an overflow hole, and the steam pressure raised to 93lb. by steam gauge. The engine was started at 2.15 p.m., at a speed of 560 revolutions per minute, and then simultaneous observations were taken every 15 minutes of the boiler pressure, net brake load, and the revolutions per minute by Messrs. Schaffer and Budenberg's tachometer (the accuracy of this instrument I had previously ascertained), from which the brake horse-powers have been calculated. The whole of my observations have been inserted in the accompanying table exactly as they were written down at the time, and the means taken from a continuous run extending over five hours' duration.

From this table it will be seen how very steadily the engine maintained its speed, and how the power developed by it gradually rose from a minimum of 18·6 B.H.P. to a maximum of 22·39 B.H.P., as the working parts warmed up. Had I been certain that the brake wheel (which was 4ft. in diameter, with light arms), could have withstood a higher speed than 600 revolutions per minute, there would have been no difficulty, as far as the engine itself was concerned, in increasing the speed to 800 or even 1,000 revolutions per minute, as both the material and workmanship seem to be of excel-

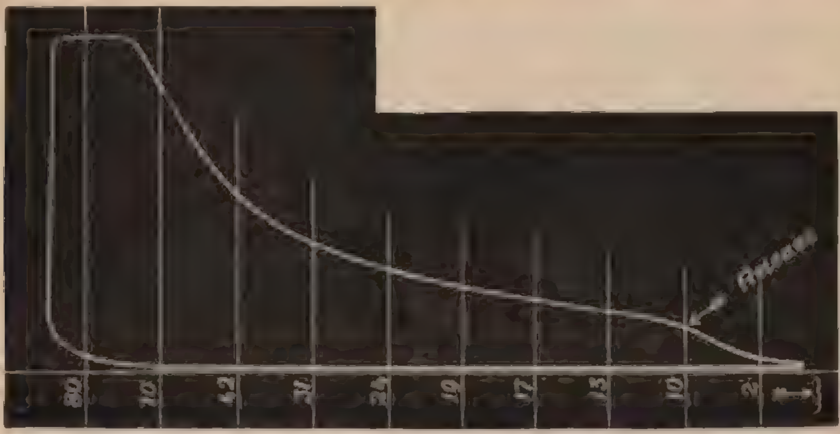
Atmospheric Line.

Mean pressure = 30·1lb.

Indicator Card taken at 200 Revolutions per Minute from the Right-Hand Side of Brown's Rotary Engine.

Left Hand. Diagram No. 8. Boiler pressure = 95lb. by gauge. Scale spring 1" = 48lb. Taken 4.46 p.m., 4/6/91.



Atmospheric Line.

Mean pressure = 30·8lb.

Indicator Card taken at 200 Revolutions per Minute from the Left-Hand Side of Brown's Rotary Engine.

Calculation for indicated horse-power and feed-water per indicated horse-power hour.

$$\text{I.H.P.} = \frac{\text{PLAN}}{33{,}000} = \frac{30·8 \times 1·86 \times 29·11 \times 574·5}{33{,}000} = 29·02.$$

Gross feed-water used per hour = 789·7lb. Gross feed-water per I.H.P. hour = $\frac{789·7}{29·02}$ = 27·2lb.

lent quality, and the only oscillating parts are the valve doors, which are duly cushioned during their back strokes, and always kept bearing upon the rotating piston by steam acting from behind them. Had this higher speed been attempted, there can be no

doubt that the consumption of steam per brake horse-power hour would have been still less than it was—viz., a mean of 37·9lb. per brake horse-power. A considerable condensation of steam no doubt took place in the steam-pipe, and in the two long indicator pipes, which were not lagged. The fall of pressure between the boiler and the cylinder, as shown by a comparison of the pressure gauge, and the indicator cards, amounting to fully 15lb. on the square inch, is due to the steam-pipe being small, right-angle bends, and the non-effective water trap. From the indicator cards taken by me prior to commencing the brake horse-power trial of five hours, as well as from those taken by me subsequently on June 4, the gross consumption of steam is only 27·2lb. per indicated horse-power hour; results which surpass not only any other rotary engine, but equal those of the very best simple expansion, fast speed, non-condensing engines (of the same power, run at the same speed and with the same steam pressure), with which I am acquainted or have seen recorded.

The indicator diagrams were taken with M'Innes' fast-speed indicator, and they are remarkably good. They show an almost equally effective power developed by the steam admitted through each rotating valve and cylinder door. The steam efficiency is only 70 per cent. of what it would have been had you been supplied with perfectly dry steam, for it appears from the indicator cards that only 19lb. of dry steam of 95lb. absolute pressure was recorded by them per indicated horse-power hour to the point of cut off, instead of an actual weight of feed-water equal to 27·2lb. per indicated horse-power. Or, 30 per cent. of the feed-water passed into the cylinder as water with the steam. The mechanical efficiency of the engine and combined heavy brake wheel and gear, or ratio of brake horse-power to indicated horse-power was 71·6 per cent., but as you will only require a small flywheel and two bearings less in the engine you make for actual work, the mechanical efficiency will no doubt then be quite equal to 80 per cent.

After steam was shut off from the engine at 7.15 p.m. feed-water was injected into the boiler until it reached the same mark on the gauge glass scale with which we started the trial run, and the feed-water barrel was filled up to the overflow hole. From these data I found that the engine had used a total of 3,948·5lb. of water during the five hours, or 789·7lb. of water per hour, which is equivalent to 37·9lb. per brake horse-power hour and 27·2lb. per indicated horse-power hour.

These results corroborate the five hours' continuous tests taken by you on May 19 last. I can account for your getting the slightly better result of 37·27lb. feed-water per brake horse-power hour from the steam-pipes leading to the indicator being left on and unjacketed throughout my trial; whereby not only a certain amount of heat energy was dissipated by radiation, but also a percentage of steam was wasted due to this additional clearance. In fact, the initial clearance appears to have been doubled by keeping these long indicator pipes on during my brake horse-power trial.

Condition of Engine after the Brake Horse-power Trial.—I had the right-hand cylinder cover removed after the five hours' run, and found all the working surfaces in perfect order. Not only were the original tool marks everywhere visible, but a fine hard glossy skin was coming up on all the wearing parts Both the workmanship and material are excellent, and bear out the good name attained by the makers, Messrs. John Lang and Sons, for accuracy and finish. I was particularly taken with the various self-adjusting packing strips between the sides and end of the piston and the cylinder, whereby you had so adjusted the compressive reaction of the back springs that the wear should take place evenly. The arrangements for renewing them (should occasion require the same to be done at any time) are exceedingly convenient and simple.

Improved Engine.—The present engine, although the fourth or fifth which you have made according to your patent, will, I understand, be still further improved upon in the one now being manufactured, by having a live steam jacket completely surrounding the cylinder and thus dispensing with the branch steam-pipes, S P_1, S P_2, as shown on the accompanying figure. It will consequently be more compact, and by having the valve gearing covered in, and he small flywheel overhung on the further side, the whole engine will be placed on one firm cast-iron sole-plate.

Space occupied by Engine.—The space occupied by your engine is less than that of any reciprocating steam engine of the same power with which I am acquainted.

Cases in which the Engine may be applied.—Your engine will be found most useful in working electric lighting and transmission of power dynamo machines, where a high speed, space, and uniformity of action are important qualifications. Also for driving yachts, steam launches, centrifugal pumps, fans, and gas exhausters, etc.

Indicator Cards.—The following two cards, selected out of a large number taken by me from the right and the left hand sides of your engine, with different strengths of springs, on June the 4th, speak for themselves. They are reproduced full size, and the necessary data has been printed on and beneath them. The mean pressures, found by ordinates in the usual way, were checked by Amsler's planimeter, which gave a slightly higher mean pressure of 30·8lb. per square inch for the two cards. The effective area of piston was taken as 29·11 square inches, the effective stroke as 1·86ft., and the revolutions as 574·5 per minute, being the mean revolutions per minute observed during the five hours' brake horse-power trial, which numbers were used in calculating the indicated horse-power. The cards were, however, taken at only 200 revolutions per minute, as it was found impossible to get an even admission line at higher speeds owing to the excessive vibration of the too long indicator pipes and the reaction of the indicator spring.

COMPANIES' MEETINGS.

EASTERN TELEGRAPH COMPANY.

Report of the Directors for the half-year ended 31st March, 1891.—The Directors submit the accounts and balance-sheet for the six months ended 31st March, 1891. The revenue for the period amounted to £383,306. 18s. 2d., from which are deducted £102,020. 10s. 4d. for the ordinary expenses and £53,144. 9s. 6d. for expenditure relating to repairs and renewals of cables, etc., during the half-year. After providing £2,274. 12s. 9d. for income tax, there remains a balance of £225,867. 5s. 7d., to which is added £78,195. 6s. 5d. brought from the preceding half-year, making a total available balance of £304,062. 12s. From this amount there have been paid:

	£	s.	d.
Interest on debentures and debenture stock	28,274	13	2
Dividend on preference shares......	20,474	3	1
An interim dividend of 1¼ per cent. on the ordinary shares	50,000	0	0
	£98,748	16	3

Leaving a balance of £205,313. 15s. 9d., from which £95,000 has been carried to general reserve. The Directors now recommend the declaration of a final dividend for the year ended 31st March, 1891, of 2s. 6d. per share and a bonus of 3s. per share, amounting together to £110,000, both payable on the 16th inst., free of income tax, and making, with the three previous payments on account, a total distribution of 13s. per share, or 6½ per cent. for the year on the ordinary shares. The balance of £313. 15s. 9d. shown at the foot of the revenue account is proposed to be carried forward to the next half-year. The revenue includes £33,283. 4s. dividends and bonus for the half-year upon the Company's investments in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies. The agreement with certain of the Australasian colonies for the reduction of rates between Europe and Australia having been concluded, the new rates were brought into operation on 1st May last, and the increase of traffic is encouraging. The laying of the triplicate cable between Aden and Bombay, referred to in the last report, was completed by the contractors on 19th April last. The operations for duplicating the Suez-Suakim section, referred to in the last report, were successfully completed on 10th March last.

The thirty-eighth half-yearly ordinary general meeting of the Company was held at Winchester House on Thursday, the chairman, Sir John Pender, K.C.M.G., presiding.

The **Chairman** stated that the receipts from messages during the six months ended March 31 last showed an increase of £1,125 over the corresponding period of last year. The working expenses for the same period showed an increase of £3,343 over last year, but included in this year's figures was a special item for repairs to the Alexandria buildings of £3,825, necessitated by dry rot appearing. Their ships had been put into thoroughly efficient order, and were ready for work at any moment. As to their staff endowment insurance fund, which amounted to £2,366, as against £1,688 last year—up to last year a certain number of their staff had taken advantage of this insurance scheme; but the Directors, after 10 years' experience, were so convinced of its advantages that they had asked the remainder to join, and nearly the whole of the staff were now contributing members. It was their policy to get the best men, and to make them as comfortable as possible in order to keep them. There was an increase in repairs and renewals of cables of £5,000. The chief expense had been in connection with the Red Sea cable, laid in 1870. They had removed all weak parts, and laid in new cable. Here was a cable that had been worked for 21 years, as against the 10 years which was once given as the life of a cable. Referring to the Red Sea cable, and the new triplicate cable to Bombay, he said it had always been their policy to keep ahead of the carrying requirements of the Company, and it was satisfactory to be able to say that the encouraging results of the traffic since the reduction of rates to Australia had fully justified the foresight and prompt action of the Directors. They had also duplicated their line to Suakim. Notwithstanding these important and extensive operations of cable laying, they did not propose any permanent addition to the capital account, but hoped to be able to meet these expenses by appropriation from time to time out of reserve fund. This policy of keeping down the capital, and keeping up the power to pay annual dividends was the secret of the strength of that Company. With the temporary assistance of the Eastern and South African Company, in which they held 59-60ths of the share capital, they would be able to meet the payments due to the Telegraph Construction and Maintenance Company. The financial transactions would take about four years to complete, and at the end of that time it was estimated that the additions to their cable system would have been paid for, and the whole amount applied out of reserve fund. It was reckoned that the amount taken out of the fund up to the completion of these arrangements would be about 1½ million sterling, and the balance remaining to reserve would be about half a million. The Company would therefore be in a better financial position than it was to-day. They had expended in repairs of cables 769 knots, and the ships who effected these repairs had sailed 112,189 knots. They now had all their cables duplicated. They had four cables betwixt Suez and Aden; three betwixt Aden and Bombay; and their total cable mileage was 26,093 miles against 8,434 in 1870, which practically was the capital

involved in that concern, and this had been attained without in the slightest degree interfering with their dividends. At the same time they had materially added to their reserve fund—that he thought was a state of things with regard to their property, that would be very difficult indeed to beat. Their African traffic last year was £49,000 less than it was two years ago, when there was a great deal of excitement there, and communication between the Cape, Kimberley, and London was very active indeed. For the moment this mining companies' traffic did not exist, but the legitimate traffic had been increasing, and the time would come round again, because there were cycles of activity and of rest, and the latter was prevailing at the present moment. There was no doubt at all that the Cape was one of the future countries to which they would have to look for a largely increased consumption of British merchandise. In a certain period these African cables would be the property of the Eastern Company, and this item would add largely to their producing power, without increasing their capital. The increase of traffic, owing to the reduction of the Australian rates, had been very satisfactory on the whole. They had not recouped themselves entirely, and he didn't expect to do so within 18 months or two years. But they had so far recouped themselves, that when the end of the year came they were very likely to carry on the experiment. The Cape had applied to be put on the same footing as Australia, but that required some negotiation. He would like to see one experiment thoroughly tested before they entered upon another. In conclusion, he alluded to his recent visit to the Mediterranean stations, and to the good order in which he found them, as well as the happy relations which existed between the Turkish and Grecian Governments and the Company's officials. He then moved the adoption of the report and accounts, and declaration of the dividend (*vide* report).

This was seconded by the **Marquis of Tweeddale**, and carried unanimously.

In answer to a shareholder, the **Chairman** said that the latest of the three cables between Aden and Bombay was laid to the southward of the others.

A vote of thanks to the Chairman, proposed by **Mr. Griffiths**, concluded the proceedings.

CHILI TELEPHONE COMPANY.

The ordinary general meeting of this Company was held on Tuesday at Winchester House, Colonel R. R. Jackson presiding.

The **Chairman** stated that the gross revenue of the Company had increased from £26,310 to £38,711, or 47 per cent., and the working expenses from £15,996 to £19,506, or only 22½ per cent. The cost of working had fallen from 61 per cent. upon the gross revenue to 50 per cent., and with the increase of the gross revenue and the diminution of the expenditure, the net revenue showed an increase from £10,314 to £19,205, or 86 per cent. Had it not been for the fall in the exchange of 25 per cent., the earnings would have been equal to 8½ per cent. upon the capital. Sufficient profit was made to pay a dividend at the rate of 7 per cent. per annum, but, taking into consideration the state of affairs in Chili, the Directors thought it wise to carry the whole amount forward. The number of subscribers had increased by 965. The expenditure on development in Valparaiso and Santiago had been very heavy. At the outbreak of the civil war the Government took over the business, but would compensate the Company in respect of any loss. He moved the adoption of the report and accounts, which was duly seconded and carried.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.

The half-yearly general meeting of this Company was held on Tuesday, at the offices, 38, Old Broad-street, Sir George Elliott, M.P., presiding.

The **Chairman** stated that during the last six months they had been employed principally in completing contracts entered into in 1890—that was, in finishing the manufacture of and in laying the Eastern Company's cables between Aden and Bombay, and the Eastern Extension Company's cables between Madras and Penang. Both of these operations were successfully carried out in the months of March and April last. Their cable factories were still at work completing a contract for the Great Northern Company. Their general current business continued to be satisfactory. They only went into the question of their accounts once a year, and that was the whole of the business of the meeting that day.

The meeting then separated.

COMPANIES' REPORTS.

DIRECT UNITED STATES CABLE COMPANY.

The half-yearly report of this Company states that the half-year's revenue, after deducting out-payments, amounted to £37,352. 19s. 5d., against £40,017. 1s. for the corresponding period of 1890, being a difference of £2,664. 1s. 7d., against the half-year under review. The working and other expenses for the same period, exclusive of cost of repairs of cables, amounted to £18,112. 19s. 8d., leaving a balance of £19,239. 19s. 9d. as the net profit of the half-year, making, with £5,510. 11s. 3d. brought forward from the previous half-year, a total of £24,750. 11s. For the corresponding period of 1890 the working expenses and other payments amounted to £17,616. 5s. 8d. Three quarterly interim dividends of 3s. 6d. each per share, amounting to £31,872. 15s., have been declared and paid during the financial year, and a final payment of 3s. 6d. per share is now proposed, making, with the three interim dividends, 3½ per cent. for the year, being a total distribution of £42,497. The balance of £3,502. 1s. on the revenue account is proposed to be carried forward.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY.

Directors: James Staats Forbes, Esq., chairman; Frederick Richards Leyland, Esq., deputy-chairman; Viscount Anson; Shelford Bidwell, Esq., F.R.S.; Ernest Villiers, Esq.

Report of the Directors to be presented to the shareholders at the annual meeting to be held at the Westminster Palace Hotel, Victoria-street, S.W., on Tuesday, July 21, at 12 o'clock.

The Directors have the pleasure of presenting to the shareholders their report and the accounts for the year ending June 30, 1891. The business of the Company has resulted in a credit balance of £72,905. 4s. 7d., out of which the Directors have appropriated the sum of £3,425. 14s. 8d. to meet loss on realisation of dynamo account, taken over at the amalgamation; and £12,371. 14s. 7d. has been absorbed by the payment of an interim dividend on the A shares at the rate of 7 per cent. per annum for the first six months of the year. The Directors recommend the payment of the following dividends on the A shares, free of income tax, and to be distributed in accordance with clause 87 of the articles of association: (*a*) At the rate of 7 per cent. per annum for the half-year ending June 30, 1891 (making 7 per cent. for the year). (*b*) 3 per cent. in completion of payment of arrears of cumulative preference dividend for the year ending June 30, 1885. (*c*) 7 per cent. in payment of arrears of cumulative preference dividend for the year ending June 30, 1886, which will absorb £47,719. 10s. 7d., leaving £9,388. 4s. 9d., which the Directors have carried to the reserve fund, in accordance with clause 89 of the articles of association. The Directors have granted licenses to several electrical firms and companies to manufacture holders and sockets for incandescent electric lamps under the Company's patents. This branch of the business will increase as electric lighting increases, and will bring a satisfactory addition to the revenue of the Company. Mr. J. S. Forbes and Mr. F. R. Leyland retire from the Board in rotation, and offer themselves for re-election as directors. The auditors, Messrs. Welton, Jones, and Co., retire, and are eligible for re-election.

PROFIT AND LOSS ACCOUNT FOR THE YEAR ENDED 30TH JUNE, 1891.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts for last week were £4,883.

City and South London Railway.—The receipts for the week ending 11th inst. were £692, against £719 for the preceding week.

Globe Telegraph Company.—The Directors propose to pay a balance dividend of 4s. 6d. per share, and to carry over a sum of £1,876.

The Eastern Extension Company announce the payment by warrant, on Aug. 1 next, of the interest for the half-year ending July 1 on their 4 per cent. mortgage debenture stock.

Western and Brazilian Telegraph Company.—The receipts for the week ended July 10, after deducting 17 per cent. of the gross receipts payable to the London Platino Company, were £3,363.

PROVISIONAL PATENTS, 1891.

JULY 6.

11447. **Improvements in electric arc lamps.** H. Dudley Norman and H. A. Payne, 29, Dorchester-place, Blandford-street, London.

11473. **Improvements in alternating-current electromagnetic motors.** Henry Harris Lake, 45, Southampton-buildings, London. (Nikola Tesla, United States.) (Complete specification.)

11476. **An improvement in key or switch sockets for electric lamps.** Reuben James Bott, 33, New Bridge-street, Blackfriars, London.

JULY 7.

11497. **An hyd**[illegible] ·Laren, Public Library, Edinbur[illegible]

11519. **Improv**[illegible] **ic cell**[illegible] Arthur L[illegible] ond[illegible] plete speci[illegible]

11526. **Improvements in and connected with portable** [illegible] **lamps, and in primary batteries and lenses for d**[illegible] **light to be used therewith.** Frederick George William James Adams, 1, Quality-court, London.

11538. **An electric traction magnetic conductor.** George Prokofiew, 13, Alkerden-road, Chiswick.

11539. **An improved dynamo machine.** George Prokofiew, 13 Alkerden-road, Chiswick.

11560. **Improvements in and relating to galvanic batteries.** George Galton Melhuish Hardingham, 191, Fleet-street, London. (John Randolph Hard and Henry Connett, United States.)

JULY 8.

11601. **Improvements in phonautographic and phonographic "forms" or material for the recording of sound vibrations.** Charles Adams-Randall, 3, Woodstock-road, Bedford Park, London.

11620. **Improvements in apparatus for preparing bleaching solution and bleaching powder by electrolysis.** Emily Eliza Lever, 77, Chancery lane, London.

11625. **Improvements in the method of and apparatus for making electrical connections.** John Henry Holmes, 6, Lord-street, Liverpool.

11630. **Improvements in and connected with moulds, rolls, or dies for manufacturing metallic plates or boxes, the said plates or boxes being more especially intended for use in electrical secondary batteries.** Anthony Spencer Bower, 47, Lincoln's-inn-fields, London.

11644. **Improvements in the lighting of trains by electricity.** Illius Augustus Timmis, 2, Great George-street, Westminster, London.

11645. **Improvements relating to combination gas and electric fittings, and to gas fittings.** Richard Brown Evered and Thomas Rudling, 45, Southampton-buildings, London.

JULY 9.

11668 **Electric lighting of ships' compasses transparent cards.** John Parkes, 13, Canning-place, Liverpool.

11712. **Improvements in or connected with electric batteries.** Henry Clay Bull, 57, Chancery-lane, London.

JULY 10.

11720. **Improvements in electrical switches.** John Henry Tucker, 2, Gordon-place, Erdington, Warwickshire.

11746. **Improvements in telegraphic apparatus.** Frans Van Houten, Monument-chambers, King William-street, London. (Complete specification.)

11756. **Improvements in electrical railway signalling.** William Brock and William Henry Radcliffe Saunders, 22, Southampton-buildings, London.

11767. **Improvements in telephone switchboards.** John Edward Kingsbury, 24, Southampton-buildings, London.

JULY 11.

11801. **Improvements in the manufacture of insulating conduits or coverings for electric conductors.** Robert D. Haines, 23, Southampton-buildings, London. (Date applied for under Patents Act, 1883, Section 103, 12th December, 1890, being date of application in United States.)

11804. **A mechanical liqueur telephone.** Henry Paul Ade, 16, Bendler-street, Berlin.

SPECIFICATIONS PUBLISHED.

1890.

9683. **Electrically driven percussive tools.** Atkinson. 8d.

13359. **Electrically propelled cars.** Siemens Bros. and Company, Limited. (Siemens and Halske.) 8d.

1891.

5508. **Electro-plating wire.** Hemming. 6d.

NOTES.

Richmond.—Tenders for wiring Richmond Town Hall, if sent, must be sent in by August 4.

Bournemouth wants the opinion of an electrical engineer as to lighting its pier with electric light.

Aylesbury.—The tenders for public lighting must be sent in by the 31st inst. to Mr. G. Fell, Aylesbury.

Writing Telegraph.—When Prof. Elisha Gray's writing telegraph becomes practical, "autogram" is proposed as the word to use.

Palermo Exhibition.—The contract for five dynamos for lighting the forthcoming exhibition at Palermo has been given to Messrs. Siemens and Halske.

Accumulator Patent.—The judgment given against M. Paul Gadot with reference to accumulators has been confirmed in the French Superior Court.

Burnley.—A new infirmary is to be erected at Burnley. Mr. Keighley, the architect, should be supplied with material for estimating the inclusion of electric light.

Colombo Tramway.—It is thought that the Contract Construction Company, who have the new tramway in Colombo in hand, will use compressed air as the motive power.

Northampton.—Messrs. Jeffery and Holden, architects, have given the contract to decorate the Northampton Town Hall to Messrs. Campbell and Smith. Electric light should be included.

Blackburn.—A new orphanage is being built at Wilpshire, Blackburn—architects, Messrs. Briggs and Wolstenholme—a possible opening for gas engine and accumulators.

North London.—The promoters of the North London Electric Lighting Order having failed to comply with certain conditions, the order has been revoked by the Board of Trade.

Cromwell-road. — Consent of the London County Council has been given to the extension of mains in Gloucester-road and Cromwell-road by the Kensington and Knightsbridge Company.

Harlow.—Tenders are invited for the public lighting of Harlow, from Sept., 1891, to April, 1892, from dusk to 11 p.m., and cleaning and storing lanterns. Particulars of Mr. W. E. Deards, Broadway, Harlow.

Electric Tramways in Norway.—A syndicate was recently formed in Christiania for the introduction of an electric tramway, and a deputation has visited Berlin, Frankfort, and Halle to report upon the systems there in use.

Austrian Telegraphs.—A universal telegraph tariff has been arranged between Austria and Germany. The charge is 3 kreuzer (·6d.) per word, with a minimum of 30 kreuzer (6d.). This tariff will come into force at the beginning of 1892.

Lighting an Artillery Encampment.—The Monmouthshire Artillery Brigade go into camp at Abergavenny on Tuesday next, and the annual inspection takes place on Bank Holiday. The camp will be lighted by electricity, the current being supplied by the Risca batteries.

Double Filament Lamp. — Herr Hiel, in the *Elektrotechnisches Echo*, No. 28, describes an arrangement for series incandescent lighting, of an incandescent lamp with two filaments, combined with an automatic switch to come into action on the failure of the first filament.

Telegraph Extension.—In answer to a question, Mr. Raikes stated in the House of Commons that by an amendment in the Post Office Bill, of which he has given notice, power will be given to local authorities to guarantee the cost of extensions of telegraph wires in districts in which they may be needed.

The Royal Society of Edinburgh.—The last ordinary meeting of the session of the Royal Society of Edinburgh was held on Monday at the Royal Institution, Lord M'Laren in the chair. A paper was read on the "Effect of Longitudinal Magnetisation on the Interior Volume of Iron and Nickel Tubes," by Prof. Knott.

Huddersfield.—The Gas Committee of the Huddersfield Corporation reported to the County Council on Wednesday that they met on the 1st inst. and decided to accept the amended tender of the Brush Electrical Engineering Company, Limited, for the installation of the electric lighting in Huddersfield at a cost of £20,640.

Saunderson Arc Lamps.—With reference to the use of hydrocarbon vapour in arc lamp carbons, and Dr Hopkinson's and Prof. Thompson's remarks there—anent, the *Bulletin de l'Electricité* hopes some third electrician will take up the question, and demonstrate whether the presence of gas on the arc is really an advantage or the reverse.

Thunderstorms.—Severe thunderstorms were experienced throughout the country at the end of last week. At Coventry the chimney of a large house was cut off level with the roof. At Nuneaton the flagstaff on Messrs. Hall and Phillips's hat factory was cleared as if by a hatchet, one half remaining, while the other half fell and damaged the roof.

Swindon.—The New Swindon Local Board have had the consideration of the Electric Lighting Acts before them. The question was left to obtain further particulars. Mr. A. D. Williams wrote to state his intention to lay down a dynamo and engine, and asked permission of the Board to take a wire across the street at the level of the present telephone wire. The Board acceded to the application.

London Chamber of Commerce.—A meeting of the council was held on Monday, Sir A. Rollit, M.P., presiding. A deputation of the Chicago World's Fair was introduced by Sir P. Cunliffe Owen, and was promised support. A deputation from the telephone companies was next received on the subject of an improved service, which was referred to a committee of the Chamber for further investigation.

Paddington.— Letters were read at last week's meeting of the Paddington Vestry from the Paddington and Bayswater Electric Light and Power Supply, Limited, and the London Electric Lighting Company, Limited, announcing their intention respectively of applying for a provisional order to supply electricity in this parish. It was decided to instruct the solicitor to oppose in both cases.

Ship Lighting.—Sir William Thomson in an interesting letter to the *Electrical Review* points out that, as regards disturbance of ship's compasses, the concentric wiring has no advantage over the one-wire system unless the outer sheathing is insulated sufficiently to prevent the return current spreading over the ship. A moderate degree of insulation, such as mounting on dry wood, would be sufficient.

Goole.—Tenders for lighting are required, for 12 months, from September 30, by the Goole Local Board. Gas is asked for, but electric light might also be acceptable. Mr. G. England is the clerk, and tenders are wanted by August 11. Goole is to have new goods offices for the Lancashire

and Yorkshire Railway Company. The various tenders will be received by Mr. C. W. Bayley, Hunts Bank, Manchester.

Edison Patents.—The case brought by the Edison Electric Light Company against the United States Electric Light Company for infringement of a patent again came before the United States Courts on Tuesday, when Judge Wallace granted a suspension for 15 days of the injunction ordered by him against the latter company pending an appeal, on condition of the defendants giving a bond to protect the Edison Company in the event of the appeal being dismissed.

Sutton (Surrey).—The Sutton General Purposes Committee recommended that, subject to a satisfactory agreement with Messrs Girdlestone and Co., no opposition be offered to any application by them for an order to furnish electric light in Sutton, as proposed by them. The recommendation was opposed, it being suggested that the Board should obtain the powers themselves. Ultimately it was resolved the question be considered by the whole Board acting in committee.

Electric Mining Plant. — A new and complete system of American electric mining plant, consisting of coal cutters, rock drills, stone and granite cutters, is being introduced by Messrs. Shippey Bros., of London, who announce that they are prepared either to sell machines right out, free from royalty, or to contract with colliery and quarry proprietors to cut coal, stone, or granite at a fixed charge upon the output. Particulars and drawings of these machines will be published shortly.

Schuckert Transformer.—Messrs. Schuckert, of Nuremberg, have brought out a new type of transformer, illustrated in the *Elektrotechnische Zeitschrift* for July 17. Imagine a heavy flat ring of iron, deeply grooved towards the centre hole to half its depth with 12 channels, making it somewhat of the form of Mordey's alternator magnet, but flat. Each of the 12 oblong cores thus made are wound with coils, the whole making a flat ring transformer. Considerable advantages are claimed from this shape of transformer.

Chelsea Electric Lighting Bill.—In the House of Lords, Lord Basing's Committee, on Thursday last week, declined to insert a clause in the recommitted provisional order relating to the electric lighting of St. Luke's, Chelsea, giving the County Council any control. This decision is one of considerable importance, as it sets aside the principle contained in all former London electric lighting bills in which the London County Council have concurrent jurisdiction with the local authority in regard to electric lighting.

St. Paul and Minneapolis Railway.—Is not the St. Paul, Minneapolis, and Manitoba Railway Company which is coming before the British public this week for £1,000,000 mortgage bonds just exactly that company on whose line (between St. Paul and Minneapolis) the trains have ceased running, owing to the vigorous opposition of the electric railway? The line spoken of is probably only a small length, but that a line is already forced to give up such a service by reason of this opposition is suggestive of troubles to come.

Mr. Sprague's Challenge.—Mr. F. J. Sprague, the well-known American electric railway engineer, has recently published a challenge to the world, in which he offers, under certain conditions, to produce an electric locomotive of greater capacity than any yet made. He proposes to take a train of six elevated railroad cars loaded, weighing, without the mo[illegible] 108 tons, to haul this train at a ma[illegible] 40 miles an hour on the level, on two miles of track on certain desig[illegible] railway lines in New York.

Torpedo Work.—Those interested in torpedoes, e[illegible] mines, and the blowing up of ships will find an int[illegible] article thereon by M. Georges Dary in *L'Ele[illegible]* for July 18. An illustration is given of an offi[illegible] watching the progress of vessels in a *camera obscura*, [illegible] to touch the contact which is to explode the mines. Another arrangement shows a range-finder and exploder—two telescopes with contacts, which when both are one the vessel makes contact for the sunk mine over which she is passing. The contacts and arrangements are shown in diagram.

Salford.—Tenders are required for lighting the Ladywell Sanatorium by an electric light installation, for the County Borough of Salford. Applications for specifications, accompanied by a deposit of £1. 1s. (which will be returned upon receipt of a *bonâ fide* tender), to be made to Messrs. Maxwell and Tuke, or Messrs. E. and F. Hewitt, architects, Manchester. Tenders, endorsed "Electric Lighting," addressed to the chairman of the General Health Committee, must be delivered to Mr. Samuel Brown, town clerk, Town Hall, Salford, by 11 a.m. on 30th inst.

Telephone Cables in the City.—At the meeting of the Commissioners of Sewers last week, Mr. Sayer presented a report of the Streets Committee relative to an application by the National Telephone Company to place a portion of their telephone cables beneath the public ways, the committee stating that, in their opinion, it was inexpedient to give consent to the application of the company to use the subsoil of the City until the contracts lately entered into for electric lighting purposes have been carried out. The recommendation was agreed to without discussion.

North London Tramways.—Negotiations are in progress for the transfer of the lines of the North London Tramways Company to the North Metropolitan Company. The London County Council have agreed to guarantee undisturbed possession until 1910, provided that the use of steam be discontinued, and that if other mechanical power be adopted it shall be subject to the same conditions as the North Metropolitan line. The North Metropolitan Company are intending to expend £25,000 in putting the road in order and introducing better methods and service.

Dover.—At last week's meeting of the Managing Committee of the Dover Town Council, the town clerk said he had received two replies to the advertisement for tenders for supplying the electric light to Dover. The first was not a tender in accordance with the requirements of the Council. It was from Messrs. Reed Bros., and offered to supply electric light to the town for the Council. The other tender, which was in proper form, was from the Brush Electrical Engineering Company, and the proposal contained very lengthy details The question was left over to a special meeting.

Helston.—Carlow is already becoming a catchword for councillors on the electric lighting question. Helston (Cornwall) pays £195 a year for gas, and, says Mr. Cade, if Carlow can have its electric light from water power five miles off, Helston could surely do it with water power only one and a half miles away. Mr. Veale, of St. Austell, had written to the Town Council to give information as to the electric lighting of that town, and a committee was eventually appointed to invite Mr. Veale to visit Helston, and to consult generally upon the advisability of electric lighting the streets and public buildings.

Underground Electric Line for Paris.—We ... at the Highway Committee of the Paris Municipal ... has decided in favour of the construction ... subterranean electric tramway from the Bois de ...logne to the Bois de Vincennes, passing under the ...oulevard Diderot, the Rue de Rivoli, the Place de la Concorde, and the Avenue des Champs Elysées. The scheme is the proposal of M. Bertier, and proposes an underground tubular line, similar to the South London line. It would be lighted by incandescent lamps.

Brixton.—The "Bonanza" General Stores at Brixton are splendidly lighted by electric light, and are simply a blaze at night, the light being as steady as possible. The Electric-avenue is also being lighted up with arc lamps, and altogether this part will be the best lighted thoroughfare in London when completed. Messrs. Clark, house furnishers, have also their place magnificently lighted, and seem to be supplying current for several other shops round about. Opposite is the "Bon Marché," which has long been lighted electrically. This corner of the metropolis is well worth a visit from electrical engineers.

Carbon Transmitters.—Mr. A. R. Bennett, writing to the Manchester papers, and referring to the recent warning advertisement of the National Telephone Company, says: "This announcement is calculated to do harm to my company, and I therefore request you to be good enough to enable me to state that the National Company's advertisement is misleading. The Mutual Telephone Company are provided with an efficient carbon transmitter, which they will put in use on July 31, and which has been submitted to eminent solicitors and patent agents, and pronounced altogether free from any patents which the National Telephone Company may retain possession of after July 30."

Sanitation and Electric Light.—The substitution of electric lighting for gas at the office of the Savings Bank Department of the General Post Office, as Mr. Preece has often urged in its favour, has been followed by a marked reduction in the amount of sick leave among its immense staff of employés. The *Lancet* believes this statement to be substantially correct, and observes "an electric lamp does not compete for the oxygen of an apartment in which it is placed, and this circumstance gives it a marked advantage over any open flame. It cannot, like some forms of gas burner, be used to promote ventilation; but in ordinary situations its harmlessness is a much more important property."

Pilsen Lamps and Carbons.—The Pilsen Electric Company have removed their offices and works from 4, Stanhope-street, Euston-road, N., to more central and extensive premises, 80, Leather-lane, Holborn. Their new works are being specially arranged for the manufacture of Pilsen arc lamps and all accessories for electric lighting and transmission of power. Several new forms and adaptations of the Pilsen lamps suitable for lighting the interiors of buildings are being prepared for the market, and also an improved kind of carbon for use with arc lamps, which are stated to show marked advantages over the carbons hitherto used. Of these further information and details will be given at no distant date.

St. Pancras Exhibition.—We are glad to learn that the St. Pancras electrical exhibition turned out a decided success financially, and the surplus is to be applied to reducing the charges to exhibitors made by the authorities for space. The beauty, interest, and success of this little exhibition is greatly to the credit of the promoters of it, and should lead to similar local exhibitions elsewhere. There was not too much to be seen, all was interesting and much of it moving or in action, the decorations were well laid out, the colours tasteful, and the rooms well decorated with palms and flowers. It was quite as interesting to the public as to the technical man, and as such achieved the success it deserved.

College Sessions.—No sooner do the last year students pass through their examinations and receive their certificates, than a new batch of scholars come forward to be provided for. Parents begin to think of sending their boys and earnest young men to turn their attention to the technical classes. England now, if not in buildings, yet in practical and earnest men, and useful laboratories, can vie with the Continent in technical education. Notices of the next year's courses at the City and Guilds Colleges at South Kensington, under Profs. Henrici, Unwin, Ayrton, and Armstrong, and at Finsbury under Profs. Thompson, Perry, and Meldola, and at University College under Profs. Ryan, give particulars of the electrical and mechanical courses for the ensuing session in October next.

Street Transformer Boxes.—A decision of some importance to electrical suppliers has just been made by the London Council. The London Electric Supply Corporation recently gave notice of intention to construct a street box, with connections, in Coventry-street. The company proposes to construct a box, which would be 5ft. square and 6ft. high inside, with a cover in the footway about 2½ft. square, and to place two transformers therein, a cellar which has hitherto been used for this purpose being no longer available. The Highways Committee are of opinion that such an interference with the public thoroughfares should not be sanctioned, and that the company should make some other arrangement. They therefore recommend that the Council do disapprove of the works referred to.

Lighthouses.—In reply to Dr. Cameron, in the House of Commons on Tuesday, Sir M. Hicks-Beach said, in compliance with an application of the Commissioners of Irish Lights, the Trinity House and the Board of Trade have sanctioned an increase in the power of the light at the Old Head of Kinsale by the substitution of a 10-wick burner for the present four-wick burner. They have declined to sanction the suggested installation of the electric light at this station, as they are advised that the position is neither a "salient headland" nor an "important land fall," as specified in the report of the Trinity House on the South Foreland experiments, and that therefore the very large expenditure of establishing an electric light station could not be justified. No application for a fog signal is before the Board of Trade.

Cardiff.—At the meeting of the Lighting and Electrical Committee of the Cardiff Corporation, on Tuesday, it was announced that the electric lighting order for Cardiff had received the Royal assent on the 3rd inst. On the motion of Mr. Carr, seconded by Mr. Peter Price, it was unanimously resolved that a committee, consisting of the chairman and vice-chairman of the committee and the borough engineer, be appointed to gain information as to the methods with regard to electric lighting which were adopted in other towns, and that they engage the services of an electrical expert in connection with their enquiry. There were two courses open to the Lighting Committee—to manufacture the electric light themselves, or to farm out their powers to some company on certain terms. The name of Mr. Carr was also added to the committee.

Fire Brigade Electric Bells.—As the period during which Messrs. Binko and Co. undertook to maintain the electric bells belonging to the London Fire Brigade will shortly expire, the Fire Brigade Committee have obtained the tenders for the maintenance of the bells for a period of three years. They think that if the contract be let for one

year only the tendency will be for the contractors to do just enough to the bells to prevent their breaking down altogether, whereas if the contract be for three years it will be to the contractors' interest to pay better attention to them. The tenders are as follows: Messrs. Binko and Co., £123. 15s.; Mr. R. Colston, £175; Mr. J. Sax, £395; and Messrs. Pyke and Harris, £500 per annum. They recommend that, subject to an estimate being submitted by the Finance Committee, the tender of Messrs. H. Binko and Co. be accepted.

Strand.—The sanction of the London County Council is given to the laying of mains in Duke-street, Adelphi, and Villiers-street, Exeter-street, Suffolk-street, and Burleigh-street, Strand, of the Electricity Supply Corporation (Gatti's), upon condition that the company give two days' notice to the Council's chief engineer before commencing the work in any of the thoroughfares specified in the notices; that the work in the Strand, when once commenced, shall be carried on continuously by day and by night; that the mains shall be laid under the footways wherever it is found practicable to do so; that the concrete floor of the road boxes be made 9in. thick; that the York stone at the top be 4in. thick; that the longitudinal girders on all the boxes be laid in 3in. stone templates the full thickness of the brickwork; and that the whole of the works shall be completed within the shortest time possible.

Arc Lamps at St. Pancras.—The Electricity Committee reported to the St. Pancras Vestry at their meeting last week that they had given consideration to the description of arc lamp columns, and lamps required for the public lighting of Tottenham Court-road. Various tenders have been received, and it has been necessary to suggest certain modifications in order to limit the cost. The lamps are, of course, the most important item, and the committee have determined to adopt the Brockie-Pell arc lamps, of which Messrs. Johnson and Phillips are the sole manufacturers, and this firm will also supply the lamp columns. The committee recommend that they be authorised to purchase and fix 26 arc lamps and columns, as already approved by the Vestry, at a cost not exceeding £38 per lamp, including lamp, fixing, column, and all necessary appliances connected with the lamp. The report was carried.

House-to-House Mains.—The London County Council having received notice from the House-to-House Electric Light Supply Company of intention to lay mains and to construct two street boxes in Pembroke-road, Earl's Court-road. The proposed works are unobjectionable, and they recommend that the sanction of the Council be given to the works referred to, upon condition that the company do give two days' notice to the Council's chief engineer before commencing the work; that the mains shall be laid under the footways wherever it is found practicable to do so; that the street boxes to be used shall be of the pattern approved by the Council; and that as an additional precaution against accident through defective insulation of the mains, each of the street boxes shall be provided with an inner as well as an outer cover, each insulated from the other as far as practicable, and that the outer cover shall be efficiently connected with earth.

Burton-on-Trent.—The Corporation of Burton-on-Trent are prepared to receive tenders for an efficient system of electric lighting suitable fo[illegible] in certain specified streets in the [illegible] and fo[illegible]tion and erection of a cent[illegible] ge[illegible]ity, and for supplying [illegible] t[illegible]ical [illegible] insulators, [illegible] *map of t*[illegible] intended to erect the station, and the streets in which the mains will be laid, may be seen, and a form of tender, [illegible] copy of conditions and general specification of the work required to be done, may be obtained on payment of [illegible] guineas (which will be returned on receipt of a bona fide tender), on application to Mr. F. L. Ramsden, engineer, Gas Works, Burton-on-Trent. Sealed tenders, endorsed "Electric Lighting," are to be delivered to Mr. T. [illegible] Whitehead, town clerk, Burton-upon-Trent, by 10 a.m. [illegible] 29th August.

City Lighting.—At the last meeting of the Commissioners of Sewers the clerk read a letter from the [illegible] Electrical Engineering Company relative to the lighting by electricity of Queen Victoria-street. In their communication the company undertook to light the street with [illegible] arc lamps, which would be in lieu of 96 gas lamps. Mr. Sly asked who would pay for the gas during the time. The chairman said the Commissioners always arranged with the gas companies under such circumstances. Mr. Sayer said he thought he ought to explain that the cost to the ratepayers would be about £150 extra. The gas must be paid for during the making of experiments with the electric light which were, of course, necessary. The subject then dropped.—It may be interesting to state in connection with this subject that measurements have been made under the superintendence of Mr. Preece, who is conjoint adviser to the Commissioners with Colonel Haywood, of the candle-power of the electric lighting. The result, which was approximate, went to show that the average illumination was about five times that of the old gas lamps.

Goldsmiths' Institute.—The Goldsmiths' Technical and Recreative Institute, New Cross, was opened on Wednesday by the Prince and Princess of Wales, and was the occasion of anticipations of much usefulness for the project. The institute is furnished with a useful electrical laboratory. The latest and most improved appliances have been supplied for ventilating by Messrs. Easton and Anderson, who have put down one of their improved electromotors, driving a Blackman fan, for supplying fresh air to the lecture halls. A "Whitehall" dynamo (Prentice's patent) is placed adjoining the electrical laboratory, and supplies current to the electromotor. It has also been proposed to work the bellows of the grand organ, shortly to be erected, by electromotors, controlled by the organist with magnetic clutches. The "Whitehall" dynamos are driven by the steam engine used for pumping and other purposes, and this installation will be an interesting example of how power may be electrically distributed for a variety of purposes throughout a large building.

Kingswood.—The Kingswood Local Board had before them last Wednesday the report of the committee who recently visited Chelmsford to inspect the electric lighting installed there by Messrs. Christie. The chairman stated that to light five miles of road 176 gas lamps would be required, placed 50 yards apart, giving 15 c.p. each, which at £3. 18s. 8d. per lamp would cost £648. 5s. 4d. In addition to this there would be £575 for fixing 176 lamps at £3. 5s. each. The total illuminating power thus given would be 2,640 candles. Under Messrs. Christie's contract the cost for electric lighting would be £621. 10s. This was cheaper than gas, and would give 5,046 c.p., as against 2,640 c.p. by gas, besides which there would be no expense for fixing the lamps. Messrs. Parfitt's tender was for £550, and they proposed to erect six more lamps, with a total of 7,000 indicated c.p. As a matter of fact, there was very little difference between the candle-power of the two [illegible]s, as Messrs. Parfitt allowed for a greater deprecia[illegible] illuminating power. It was unanimously resolved

to light the district by electricity, and Messrs. Parfitt's tender of £550 was accepted.

Electric Railways.—The following interesting bits are given in Mr. F. Brown's report to the Walsall Corporation. Mr. F. Sprague stated to him that there had not been a single fatal accident from current used on electric railways. At St Paul's, Minneapolis, he found 1,200-h.p. engines driving 12 dynamos, providing current for 135 motor cars, running on 46 miles of double track. The boilers are Babcock and Wilcox, fired by oil at two cents a gallon. The electric cars have run the ordinary steam railway off the road, giving better service at half cost. At Cleveland he found a car passed every six seconds, or about 11 a minute, all well loaded. At Buffalo they have 80 miles at work and 50 more are going down, with a total of 300 cars. At Pittsburgh the Pleasant Valley Company have 780 h.p. at work. The Perrysville line is one of the most difficult in America, being all uphill, a gradient of 12½ per cent., or one in eight, and curves all the way of short radius. The car travelled well at six to eight miles an hour, starting on the curves and without jerks. At moment of starting each car took about 80 h.p. He learnt that in every lawsuit decision about earth circuits the decision had gone with the tramway company.

Illuminating Efficiency of Lamps.—M. A. Witz has communicated to the French Académie des Sciences the result of his researches upon the illuminating efficiency of some of the ordinary forms of lighting apparatus. The following comparative table is obtained :

Source.	Expenditure.	Intensity. Carcel.	Intensity. Candle.	Calories. Per carcel-hour.	Calories. Per candle-hour.
"L'Etoile" candle...	10·5 gr. pr. hr.	1/6·5	1·4	716	79·5
"Bengel" gas burner	105 litres ,,	1	9	567	63
Recuperative	35 ,, ,,	1	9	189	21
Incandescent electric lamp	3·5 watts per candle	1/6·5	1·4	20	2·22
Arc lamp	·5 ,, ,,	1	9	4	·44

The best absolute efficiency is, of course, that of the arc lamp.

It is more economical to burn gas on an engine for the production of electric light than to use it direct in gas burners, M. Witz concludes. He has substituted 16 arcs and 71 16-c.p. incandescents for six large double recuperative gas lamps, 91 ordinary jets, and 19 batswing burners. Exact measurement showed this electric light to give 15 per cent. more light than the gas lamps for the gas ; and the engine driving the dynamo consumed only 21,500 litres of gas against 26,000 litres per hour of the gas lamps.

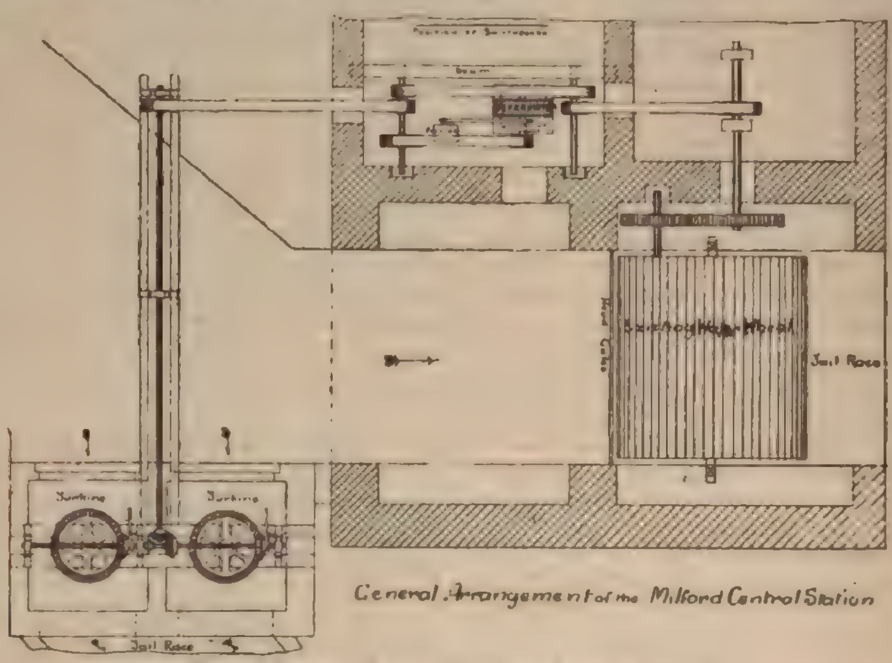
Austrian Companies.—Last week the electrical companies in Vienna published for the first time, says the Vienna correspondent of *Industries*, their reports on the progress of business during the past year. The Vienna Electricity Company, which employs the machinery of Messrs. Siemens and Halske, though it has been working for a year and a half, is not yet in a condition to pay a dividend. There is, however, no deficit, and £23,440 was carried forward to next year's account. The International Electricity Company, which employs Messrs. Ganz and Co.'s machinery, has paid interest out of capital at the rate of 5 per cent. on its capital of £281,250. As the company has spent £168,000 on its Vienna central station, whose cable system is 22 miles in length, and on its central station at Fiume, this rate of interest was much too high. The first balance-sheet of the company consequently shows a deficit of £4,213. On the whole, these companies have done a fairly satisfactory business during the past year. On the Stock Exchange, however, electrical companies have lost credit to some extent, and the Anglo-Austrian Bank has been obliged on this account to postpone the intended issue of shares of the Budapest Electrical Railway. The Prague Electrical Tramway, worked on the system of Herr Krizik, who is the inventor of the well-known Pilsen arc lamp, has been completed, and the preliminary trials of the tramway took place on the 8th inst.

York.—An adjourned meeting of the York City Council was held on Tuesday to consider the electric lighting of the York Law Courts. Alderman Agar moved the adoption of the report of the Municipal Offices Committee, who recommended that the courts of justice, police stations, etc., in Clifford-street, be lighted by electricity, and that the tender of Messrs. Benham and Sons, London, at the sum of £552. 11s., according to specifications submitted by Mr. Sydney Hargraves, electrical engineer, New Bridge-street, London, be accepted, and that Mr. Hargraves be appointed electrical engineer in connection with the wiring of the building, his remuneration to be 35 guineas, to include all charges for revising specifications and plans, reporting on estimates, superintending the wiring, testing and passing the same on completion, and all travelling and incidental expenses. Mr. Mansfield moved as an amendment that the report be referred back to the committee, and Mr. Tripp, in seconding the amendment, complained that the committee had come before the Council with a report recommending electricity when they were not prepared to say whether gas or electricity was the cheapest. Mr. Dodsworth said it was intended by the committee that the plant for lighting the public building should be part of the system for lighting the whole city. Mr. Dickenson thought they would do well to see whether they could themselves successfully carry out the electric lighting of their building. Mr. Mann also moved another amendment, to adopt the report of the committee, and providing also that the police station and fire brigade buildings be lighted with gas, as well as having the electric wire laid on. The amendment was negatived, and the report was adopted.

Safety in Theatres.—We have received from Mr. S. Wilkins, Mansion House-chambers, E.C., a small pamphlet (1s.) by M. Réné Résuche, upon "Crushes and Crowds in Theatres in Cases of Fire or Fright," describing a method which the inventor is seeking to introduce for the better safety of theatres. M. Résuche gives some interesting and suggestive figures both of the numerous fires, amounting to 32 in 1889, and 50 in 1890, in theatres in various parts of the world, together with a table of the total receipts from the theatres of Paris, which goes to show that although there has been a steady rise in receipts (barring the war years) from 1848 to 1884, yet in 1885 accounts were everywhere current of several very disastrous fires, and since then, even during the exhibition year, the receipts have been going down, till there is now a deficit of nearly three-quarters of a million sterling from the calculated average. This is almost entirely due, he thinks, to the fear of fire, and he urges theatre proprietors to make such arrangements as shall ensure absolute safety and ease of exit. He has constructed models in which movable doors or walls of double iron plates filled in with cork or other material are built at suitable places in the outside walls. These either drop down like shutters, giving exit to outside balconies, or, in another model, fall outward like drawbridges, themselves forming a balcony. In case of panic these are all loosed simultaneously by electric or pneumatic contact, and the public find everywhere around them exits to the outside staircases. Panic would thus be avoided, and safety could be assured without the necessity for entire reconstruction of the whole premises, as now seems the only alternatvie. The pamphlet is well worthy of study by those associated with theatre working, and M. Résuche adduces very favourable comments from the Paris papers.

CARLOW.

An invitation from Messrs. J. E. H. Gordon and Co. to be present at what may be termed the inauguration of the electric lighting system at Carlow on Monday, July 13th, directed our steps to the mail leaving Euston at 8.20 on July 12th. Travellers by the L. and N. W. R. are fully acquainted with the excellent manner in which these trains are run. For a moderate fee sleeping accommodation can be had, and one half the physical inconvenience of travel avoided. No less admirable is the boat service from Holyhead to Kingstown. The train arrived punctually at Holyhead, and a few minutes only was needed to see the travellers in their berths, and the boat well on its journey to Kingstown. A quick passage over a sea as smooth as a millpond, a rush to the mail train awaiting the arrival of the boat, a short speedy ride, and we reach Dublin. No time, however, must be lost, and a trio mount a jaunting-car to get across the city to the other station and to breakfast, the fourth member of the party following a few minutes later. Dublin is not yet [illegible] there is no difficulty in getti[illegible] A [illegible] we leave for Carlow, which [illegible] :k. T[illegible] no rest for the representatives of newspapers when on the warpath—that is, when collecting information—hence within a short half hour of our arrival at Carlow, the party, reinforced by others previously in the town, are found in a roomy boat belonging to the Carlow Boat Club, with a willing horse upon the towpath, starting for a five mile trip on the waters of the Barrow to Milford, where in a disused corn mill the generating station will be found.

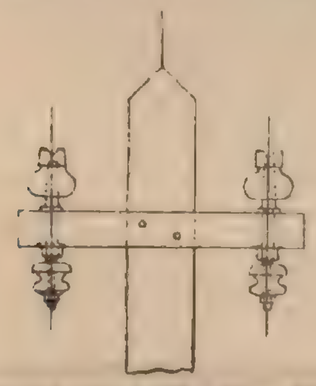


Plan of Dynamo Room and Water Power at Milford.

Before recording more of this journey, it will be well to speak of Carlow. Situated some 56 miles south of Dublin, at the confluence of the Burren and the Barrow, in the midst of a purely agricultural district, it is scarcely the type of town one would foretell as taking the lead in introducing a new illuminant. But in Carlow gas is dear and not of the highest quality, and the gas management has not conciliated the Town Commissioners, so that lately the public lighting has been by means of oil lamps. Here, then, was a fine opening for the electrical engineer, and while in Ireland, through the proposed Dublin installation, Mr. J. E. H. Gordon was made acquainted with the position of Carlow and the aspirations of the Commissioners. No time was lost. A temporary installation was put up, proof positive given as to the efficacy of the electric light, terms offered and accepted,

Dynamo Room at Milford.

and the permanent installation commenced. From one point of view, however, it seems somewhat natural that Carlow should take the lead among Irish towns. If we mistake not, Prof. Tyndall, whose name stands in the front rank of scientific worthies of the nineteenth century, first saw the light "just a stone's throw away from Carlow's environs, in her twin borough—old Leighlin," and will be one of the first to recognise the suitability of electricity to assist in utilising the waste water power of the district. According to Mr. Brophy, in his "Carlow Past and Present," the town ought to be termed the "Athens of Leinster," because "it has more the appearance of a city than of an ordinary Irish country town"; its streets are not straggling and irregular; the leading streets converge from four different points on the exact centre, the public buildings assume classic styles of architecture, and so on—good reasons to an Irish author, but, like many other statements, hardly convincing. We must admit, however, that the streets are fairly favourable to electric lighting, much more so, indeed, than is the case in many old and in not a few modern towns. Again, the town is fairly compact, an advantage not to be despised when the cost of mains is considered. Returning now to our visit. Given a warm, sunny day, pleasant companions, pretty scenery, and what is more enjoyable than a river journey? One feature in connection with the Barrow was noticeable. There was absolutely no other traffic upon its waters, and weeds were rapidly blocking the stream—thanks to a strike in Dublin, whereby those who usually worked the barges, and those who cleaned the stream, were idly standing at the bridge, or to be found under worse conditions elsewhere. Arriving



Oil Insulators for carrying Line and Return.

at Milford, the dynamo-room, in the old mill belonging to Major Alexander, was visited. Here is an Elwell-Parker 50-kilowatt alternator with its exciter, driven by belts from a shaft driven by the huge waterwheel of the old mill. The waterwheel is about 15ft. diameter by 20ft. in length, and under present conditions all the power required can be easily obtained, but in flood time the tail rises till the head of water available is only about 5ft., so arrangements are rapidly approaching completion, when a couple of turbines will be available, and these, together with the waterwheel, which could still be used, would supply some 300 h.p. We illustrate the plan of the dynamo-room, which is fitted with the usual switchboard and measuring apparatus, with a transformer to run the lights required in the works. From the switchboard the mains run to an upper floor, leaving the mill high up, are carried across the river, and run, 20ft. high, on poles along the towpath of the Barrow river, the use of which has been granted at a nominal rent by the Barrow Navigation Company. Fowler-Waring cables are used, and, to make doubly sure, both line and return are carried on Johnson-Phillips oil insulators. The cables fulfil the Board of Trade requirements, which many people think too stringent. The current is generated at 2,500 volts, and transformed down to 50 volts for use. The loss in transmission is now found to be about 2½ per cent., but the calculations have been made to allow of a loss of 10 per cent. when the whole of the public and private lighting is in full swing. The cables are, as we say, brought overhead into a small switchhouse in the centre of the town, where the controlling apparatus for the town lighting is situated, and from whence the circuits can be tested. The distributing cables are installed over about five miles of streets, and are carried on posts set up at the edge of the footpaths, and some of the lamps higher than the others carry the arc lamps. The lamps, in fact, are nearly 50ft. above the street level. They are of the Brockie-Pell type, some fitted with globes, and some with lanterns. Those of the lantern shape seem to find most favour.

The public lighting of the streets has hitherto been carried out by 100 oil lamps of 10 c.p. each, and costing the Town Commissioners £104 per year for a total light of 1,000 c.p. It is now carried out by 13 arc lamps of 1,200 c.p. each, and 40 incandescents of 16 c.p. each, giving a total light of 25,840 c.p., or 25 times the former amount, and for this the Commissioners pay £170 a year.

The present plant provides, in addition to the public lighting, for about 1,200 incandescent lamps in shops and private houses, and these are charged at a fixed rate per annum, calculated to be about 5 per cent. less than the customer's former gas bill.

The transformers which transform the current from the high-pressure form, necessary for carrying it to a distance, to the low pressure of 50 volts at which it is utilised, are fixed upon conveniently selected posts at intervals throughout the town. No transformer is in any building or

Street Lamppost, carrying Transformer.

private property, or in any way within reach of the public. This is an important element of safety.

The low-pressure system of mains consists of bare copper ropes or strands carried on porcelain insulators, and these are fixed partly on the same posts that carry the high-pressure wires, and partly on the fronts of the houses.

Messrs. Gordon and Co. contend that in the ordinary system of placing transformers it is not profitable to supply a customer unles he will take 15 or 20 lamps, but by the system introduced into Carlow the small customer using one, two, or three lights is, *pro rata*, as good a customer as anybody else, and there seems to be much truth in this contention. We trust that experience will go to prove that many private residents will install a few lights when only a few are really required, so that the summation of these installations will lead to demand to the full capacity of the works.

This point is absolutely essential if electricity is ever to cease to be a luxury of the rich and to become the poor man's light.

Messrs. Gordon claim that they have solved the question, and have brought the light within the reach of anyone who is able to afford gas.

The machinery was started for the first time a few minutes after midnight on Wednesday, June 24, and has

run without a hitch or difficulty from the moment of starting.

Messrs. Gordon's engineer-in-charge, Mr. Meredith (son of Mr. George Meredith, the well-known novelist), together with an English foreman, has carried out the work entirely by local labour. The whole of the erection of poles, placing of machinery, wiring of houses, etc., has been done by the ordinary labourers of the district, of whom between 40 and 50 have been employed ever since the work was commenced in December last.

We have in a previous issue referred to the inaugural banquet, and it only remains to add that the various deputations seemed highly pleased with the installation, and went away with the view to use their best endeavours to get the light introduced into the various towns represented by them.

It is difficult to calculate what effect this introduction of a new enterprise may have upon the future political and social development of Ireland.

It is expected that the next town that will be completed by Messrs. Gordon will be Larne, the rising sea port and holiday resort near Belfast, the importance of which is rapidly increasing since the opening of the new Larne and Stranraer mail route, a portion of which will be lighted up on August 1st.

Negotiations are in progress with various other important towns.

NIBLETT'S SOLID ACCUMULATOR.

Of late years many attempts have been made to overcome that inherent weakness of all known electric storage batteries—viz., the warping, buckling, and rapid disintegration of its elements—but so far but little real advance seems to have been made. The want of a really good, inexpensive, mechanically strong cell of high capacity and small weight has been keenly felt by all those who have been associated with electric tramcar work, electric launches, and the almost innumerable other purposes where some form of portable means of storing electrical energy is an essential. The many suggested plans for producing locomotion by means of electricity are just now attracting much attention, and there is every prospect that at no very distant period this branch of electrical engineering will become fully as important as the electric lighting industry is at present. Much may be said in favour of the suggested methods of conveying the electrical energy through overhead conductors, the utilisation of the road rails, or separate insulated high-conductivity conductors as the leads, or the mode of "picking up" the current from underground mains. If, however, a secondary battery can be produced which shall be capable of withstanding the excessive electrical strain incidental to a rapid and irregular rate of discharging, and the mechanically disruptive effect which always seems to attend concussion and jolting, and greatly tells upon all forms of accumulators when used for traction purposes, then the self-contained storage battery system would be found to compare most favourably with any of them, both in point of simplicity and economy.

There can be but little doubt that there is at the present time an enormous field for a cell which will combine large capacity with small weight, and great mechanical solidity. Some little time ago great hopes were entertained that the solidity problem had been solved by the introduction of Dr. Schoop's solid electrolyte. In this country some practical trials have been made with Mr. Barber-Starkey's method of forming solid cells, by substituting for the fluid electrolyte a mixture of wood sawdust and plaster of Paris, which, when set, was moistened with dilute sulphuric acid. In America, the semi-solid batteries of Messrs. Hatch and Wiswell, and Mr. Pumpelly, are said to be doing good work. One great drawback to the employment of a vis[illegible] gelatinous, or solid porous electrol[illegible] [illegible]des in [illegible] [illegible]t when such substances are in [illegible] [illegible]ween [illegible] [illegible]se circulatio[illegible] the liquid [illegible] the ac[illegible] of their el[illegible] [illegible]al acti[illegible] as the [illegible] [illegible]hich

necessary reactions take place, it seems highly pr[illegible] that anything which prevents its free access to the [illegible] material, or in any way impedes its circulation, m[illegible] detrimental, and lead to loss of efficiency and capacity.

Some new forms of mechanically solid storage cells [illegible] recently been devised by Mr. J. T. Niblett, which [illegible] addition to their absolute mechanical solidity, posses[illegible] advantages of simplicity of construction, high cur[illegible] capacity, and the property of being able to withstand [illegible] high rates of charge and discharge—most important p[illegible] in storage cells when used for traction or portable purp[illegible]

The new cell in its simplest form is of the Planté [illegible] lead type, but the same method of construction has [illegible] applied to the lead, lead-peroxide, lead-zinc, copper-[illegible] and many other combinations with the acid or alk[illegible] electrolytes. Each element consists of a highly cel[illegible] mass of material which is capable of absorbing [illegible] sufficient quantity of the liquid electrolyte for th[illegible] due performance of all the possible and necess[illegible] chemical reactions Between each electrode is place[illegible] thin highly porous inert diaphragm, which is found not [illegible] materially increase the internal resistance, and which ser[illegible] to complete the solid character of the cell. In one form [illegible] outer metallic containing chamber constitutes one electro[illegible] of the couple, and when the cells are joined up to form [illegible] battery, an extension of one side of the metal case ser[illegible] as the electrode of the opposite polarity in the follow[illegible] cell, and so on throughout the series. The cellulous ma[illegible] which constitutes the elements is prepared by a very sim[illegible] mechanical process, and it is made electrically active eithe[illegible] by the ordinary "forming" operation, by chemical mea[illegible] or in some cases by the electrolytic deposition of chemica[illegible] spongy metal. The method of formation will naturally depe[illegible] upon the nature of the materials which constitute the ce[illegible]

Owing to the cellulous nature of these elements th[illegible] liquid contained within their pores is continually circulati[illegible] throughout the mass, the slight evolution of gas which [illegible] continually occurring both during the charge and discharge being quite sufficient to effect this. Any expansion of the elements occurring in the formation or working, which in other batteries too frequently results in the buckling and disintegration of the plates, and consequent troubles due to short-circuiting, has practically no effect on a battery constructed according to the improved plan, as the whole is solidly con[illegible] tained within a rigid casing, which may be of any strength requisite, and the elements are incapable of displacement. The cellular nature of the electrodes gives them the peculiar property of self-regulating their own internal resistance. If the cell be charged at a too high rate, or when it is on the point of receiving the full complement of its charge, the gas generated tends to drive the electrolyte from the pores of the electrodes, and itself to remain imprisoned therein, thereby greatly increasing the internal resistance. In the same way, as a discharge proceeds the occluded gas re-enters into chemical combination, and allows the liquid to refill the pores, and thereby exposes more active surface. As a means of inserting a hydrometer to test the density of the electrolyte, one or more perforated metal tubes extend throughout the whole depth of the active material, the tubes being of such dimensions as to freely allow of the insertion of the density testing apparatus. By the adoption of Mr. Niblett's plan, any of the ordinary forms of electrodes, whether of the plain lead, the grid, or the compressed slab types, can readily be made up into the solid form without in any way decreasing their current capacity per pound of complete cell, or their general efficiency.

So far the new battery, in its commercial form, has not been put to any prolonged practical trials, but we understand that a battery, consisting of 12 experimental cells were constructed over two years ago, and these have been purposely subjected to much bad and improper treatment, the result being that at the present time the whole of the cells are in excellent condition, and show no signs whatever of deterioration. In the absence of the necessary data as to capacity, efficiency, internal resistance, and the E.M.F.'s of the various combinations, we are, of course, quite unable to say how these cells compare with other well-known forms; but we are assured that experiments have proved [illegible]t they compare most favourably, both in point of [illegible]ity, efficiency, and weight, with any cell yet produced

There can be no doubt that an inexpensive, light, and mechanically solid storage battery is a great desideratum, as there is at the present time a large and increasing demand for portable batteries suitable for such purposes as safety lamps, such as are used in coal mines, petroleum ships, gunpowder mills, gas works, etc. For tramcar propulsion, electric buses, electric launches, and submarine boats, and also for supplying the energy for train, carriage, and other forms of portable electric lighting, a battery capable of withstanding a considerable amount of jolting and rough treatment is much needed. A large number of portable storage batteries are now being employed both in the army and navy, but it is found that the rough treatment they receive seriously tell upon them.

As the battery we have just described seems to possess most of the essentials of a really good portable medium for storing electrical energy, it should be found of much service for the purposes we have enumerated.

In the new cell the whole of the active material is held solidly in position, and cannot move, and it therefore follows that the necessary current collectors may be very light, and in practice it is found that a very high current capacity per pound of complete cell may safely be obtained.

One of the small cells we were shown was constructed for traction purposes, and as an indication of its capabilities the following data is given:

Height	7½in.
Breadth	5in.
Width...............................	5in.
Total weight	11lb. 7oz.
Best rate of charge	5 to 10 amperes.
Best rate of discharge	3 to 6 amperes.
Working current capacity......	30 ampere-hours.
Working energy capacity......	60 watt-hours.

A small two-cell battery, made for such purposes as safety hand-lamps, etc., was of the following dimensions:

Height	5in.
Breadth	3¾in.
Width	1⅞in.
Total weight	2lb. 10oz.
Best rate of charge	1 to 2 amperes.
Best rate of discharge	0·5 to 1·0 ampere.
Working current capacity ...	3 ampere-hours.
Working energy capacity ...	12 watt-hours.

These batteries were of the Planté type, and were simply formed by the ordinary process of charging and reversing. Naturally, as the size and capacity increases the comparative weight decreases. The cells shown to us consisted of a light leaden chamber, forming the negative pole, and these were firmly cemented into a strong wooden outside case Special terminals, which are really elongations of the electrodes, are used. As an example of the mechanical solidity of the Niblett accumulator, the cell exhibited was thrown with some violence several times to the floor without suffering the least injury.

ELECTRIC LIGHTING IN LONDON.

Mr. R. Percy Sellon, M.I.E.E., at the last weekly meeting of the Balloon Society in St. James's Hall, gave an address on the above subject. He gave a sketch of the early history of electric light, and of the first Electric Lighting Act of 1882. Six years later the Electric Lighting Act of 1888 was passed, extending the period of tenure from 21 to 42 years, which, though far from placing electric lighting on the favourable conditions under which gas started, has resulted in an immense development. Nine companies and one local authority are now supplying electricity over the greater part of London, with an aggregate capital of £3,000,000, and already some are paying dividends. The equivalent of half a million lamps of 8 c.p. are now distributed, and additions are being rapidly made; some of the largest have trebled and quadrupled their production within the last 12 months. Mr. Percy Sellon described very fully the contract entered into between the Commissioners of Sewers of the City of London and the Brush and the Laing-Wharton Companies, which constitutes a scheme of an unusually comprehensive character. As regards public lighting, it is the first instance in this country where a public authority has courageously determined to wholly abandon other illuminants in its streets, large and small, in favour of electric lighting. Arc lamps to be placed in the main thoroughfares, and incandescent lamps in the side streets. Then under an extensive scheme of private lighting, current will be supplied to offices, warehouses, and business premises. Upon the question of cost, Mr. Sellon expressed his opinion that the adoption or otherwise of electric light would turn less upon a question of actual cost in pounds, shillings, and pence per quarter than upon a higher standard of comfort among the people. The fact that the City authorities are willing to pay more than twice as much for public lighting by electricity as they have paid previously for gas, points to this conclusion. Mr. Sellon then dealt with the question of danger to life and fire risk, showing that the Board of Trade and fire office rules had rendered these less than than those of gas or oil. At the conclusion of the paper a resolution was carried that it was not desirable that the Legislature should unduly interfere with the development of the electric lighting industry.

EXPERIMENTS WITH ALTERNATE CURRENTS OF VERY HIGH FREQUENCY AND THEIR APPLICATION TO METHODS OF ARTIFICIAL ILLUMINATION.*

BY NIKOLA TESLA.

(Continued from page 64.)

But of all the views on nature, the one which assumes one matter and one force, and a perfect uniformity throughout, is the most scientific and most likely to be true. An infinitesimal world, with the molecules and their atoms spinning and moving in orbits, in much the same manner as celestial bodies, carrying with them and probably spinning with them ether, or in other words, carrying with them static charges, seems to my mind the most probable view, and one which, in a plausible manner, accounts for most of the phenomena observed. The spinning of the molecules and their ether sets up ether tensions or electrostatic strains; the equalisations of ether tensions sets up ether motions or electric currents, and the orbital movements produce the effects of electro and permanent magnetism.

About 15 years ago Prof. Rowland demonstrated a most interesting and important fact—namely, that a static charge carried around produces the effects of an electric current. Leaving out of consideration the precise nature of the mechanism which produces the attraction and repulsion of currents, and conceiving the electrostatically charged molecules in motion, this experimental fact gives us a fair idea of magnetism. We can conceive lines or tubes of force which physically exist, being formed of rows of directed moving molecules; we can see that these lines must be closed; that they must tend to shorten and expand, etc. It likewise explains in a reasonable way the most puzzling phenomenon of all, permanent magnetism, and, in general, has all the beauties of the Ampère theory without possessing the vital defect of the same—namely, the assumption of molecular currents. Without enlarging further upon the subject, I would say that I look upon all electrostatic current and magnetic phenomena as being due to electrostatic molecular forces.

The preceding remarks I have deemed necessary to a full understanding of the subject as it presents itself to my mind.

Of all these phenomena the most important to study are the current phenomena, on account of the already extensive and ever-growing use of currents for industrial purposes. It is now a century since the first practical source of current has been produced, and ever since the phenomena which accompany the flow of currents have been diligently studied, and through the untiring efforts of scientific men

* Lecture delivered before the American Institute of Electrical Engineers at Columbia College, New York, May 20.

the simple laws which govern them have been discovered. But these laws were found to hold good only when the currents are of a steady character. When the currents are rapidly varying in strength, quite different phenomena, often unexpected, present themselves, and quite different laws hold good, which even now have not been determined as fully as is desirable, though through the work, principally of English scientists, enough knowledge has been gained on the subject to enable us to treat simple cases which now present themselves in daily practice.

The phenomena which are peculiar to the changing character of the currents are greatly exalted when the rate of change is increased, hence the study of these currents is considerably facilitated by the employment of properly constructed apparatus. It was with this and other objects in view that I constructed alternate-current machines capable of giving more than two million reversals of current per minute, and to this circumstance it is principally due that I am able to bring to your attention some of the results thus far reached, which I hope will prove to be a step in advance on account of their direct bearing upon one of the most important problems—namely, the production of a practical and efficient source of light.

The study of such rapidly alternating currents is very interesting. Nearly every experiment discloses something new. Many results may, of course, be predicted, but many more are unforeseen. The experimenter makes many interesting observations. For instance, we take a piece of iron and hold it against a magnet. Starting from low alternations and running up higher and higher, we feel the impulses succeed each other faster and faster, get weaker and weaker, and finally disappear. We then observe a continuous pull; the pull, of course, is not continuous; it only appears so to us; our sense of touch is imperfect.

We may next establish an arc between the electrodes and observe as the alternations rise that the note which accompanies alternating arcs gets shriller and shriller, gradually weakens, and finally ceases. The air vibrations, of course, continue, but they are too weak to be perceived; our sense of hearing fails us.

We observe the small physiological effects, the rapid heating of the iron cores and conductors, curious inductive effects, interesting condenser phenomena, and still more interesting light phenomena with a high-tension induction coil. All these experiments and observations would be of the greatest interest to the student, but their description would lead me too far from the principal subject. Partly for this reason, and partly on account of the vastly greater importance, I will confine myself to the description of the light effects produced by these currents.

In the experiments to this end a high-tension induction coil or equivalent apparatus for converting currents of comparatively low into currents of high tension is used.

If you will be sufficiently interested in the results I shall describe as to enter into an experimental study of this subject; if you will be convinced of the truth of the arguments I shall advance, your aim will be to produce high frequencies and high potentials—in other words, powerful electrostatic effects. You will then encounter many difficulties, which, if completely overcome, would allow us to produce truly wonderful results.

First will be met the difficulty of obtaining the required frequencies by means of mechanical apparatus, and, if they be obtained otherwise, obstacles of a different nature will present themselves. Next it will be found difficult to provide the requisite insulation without considerably increasing the size of the apparatus, for the potentials required are high, and owing to the rapidity of the alternations the insulation presents peculiar difficulties. So, for instance, when a gas is present, the discharge may work by the molecular bombardment of the gas and consequent heating, through as much as an inch of the [illegible] solid insulating material, such as glass, hard rubber, [illegible] sealing-wax, etc., in fact, thr[illegible] known i[illegible] stance. The chief requisite [illegible] ion of [illegible], therefore [illegible]
exclusion [illegible] matt[illegible]

In gen[illegible] hut be[illegible]
which pos[illegible] ity, s[illegible]
as glass, [illegible] vh[illegible]
while t[illegible]

inductive capacity, such as oils, for instance, the die[illegible] losses being no doubt greater in the former. The dif[illegible] of insulating, of course, only exists when the potentia[illegible] excessively high, for with potentials such as a few tho[illegible] volts there is no particular difficulty encountered i[illegible] veying currents from a machine giving, say, 20,000 al[illegible] tions per second, to quite a distance. This numb[illegible] alternations, however, is by far too small for [illegible] purposes, though quite sufficient for some practical [illegible] cations. This difficulty of insulating is fortunately [illegible] vital drawback; it affects mostly the size of the appa[illegible] for, when excessively high potentials would be used, [illegible] light-giving devices would be located not far from [illegible] apparatus, and often they would be quite close to it. [illegible] the air-bombardment of the insulated wire is depende[illegible] condenser action, the loss may be reduced to a tri[illegible] using excessively thin wires heavily insulated.

Another difficulty will be encountered in the cap[illegible] and self-induction necessarily possessed by the coil. I[illegible] coil be large—that is, if it contain a great length of wir[illegible] will be generally unsuited for excessively high frequen[illegible] if it be small, it may be well adapted for such freque[illegible] but the potential might then not be as high as desired [illegible] good insulator, and preferably one possessing a [illegible] specific inductive capacity, would afford a twofold ad[illegible] tage. First, it would enable us to construct a very [illegible] coil capable of withstanding enormous difference[illegible]

Fig. 1.

potential; and secondly, such a small coil, by reason o[illegible] smaller capacity and self-induction, would be capable [illegible] quicker and more vigorous vibration. The problem [illegible] of constructing a coil or induction apparatus of any [illegible] possessing the requisite qualities I regard as one of [illegible] small importance, and it has occupied me for a consider[illegible] time.

The investigator who desires to repeat the experim[illegible] which I will describe, with an alternate-current mach[illegible] capable of supplying currents of the desired frequency, [illegible] an induction coil, will do well to take the primary coil [illegible] and mount the secondary in such a manner as to be abl[illegible] look through the tube upon which the secondary is wou[illegible] He will then be able to observe the streams which [illegible] from the primary to the insulating tube, and from th[illegible] intensity he will know how far he can strain the [illegible] Without this precaution he is sure to injure the insulati[illegible] This arrangement permits, however, an easy exchange [illegible] the primaries, which is desirable in these experiments.

The selection of the type of machine best suited for [illegible] purpose must be left to the judgment of the experiment[illegible] There are here illustrated three distinct types of machi[illegible] which, besides others, I have used in my experiments.

Fig. 1 represents the machine used in my experime[illegible] [illegible] this institute. The field magnet consists of a r[illegible] [illegible]ght iron with 384 pole projections. The armat[illegible] [illegible] a steel disc to which is fastened a thin, carefu[illegible] [illegible] of wrought iron. Upon the rim are wou[illegible]

several layers of fine, well annealed iron wire, which, when wound, is passed through shellac. The armature wires are wound around brass pins, wrapped with silk thread. The diameter of the armature wire in this type of machine should not be more than one-sixth of the thickness of the pole projections, else the local action will be considerable.

Fig. 2 represents a larger machine of a different type. The field-magnet of this machine consists of two like parts which either enclose an exciting coil, or else are independently wound. Each part has 480 pole projections, the

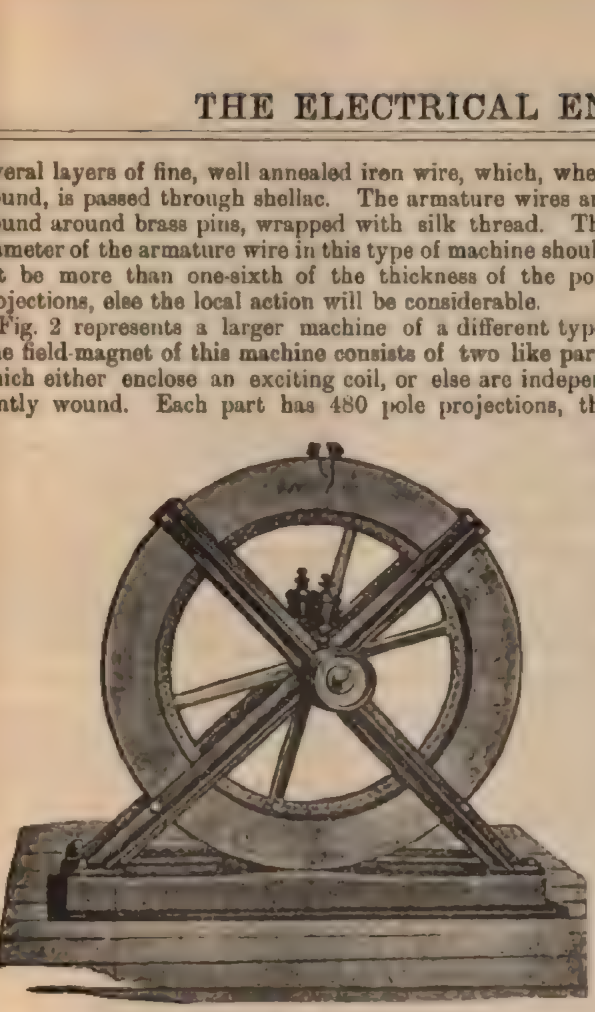


Fig. 2.

projections of one facing those of the other. The armature consists of a wheel of hard bronze, carrying the conductors which revolve between the projections of the field magnet. To wind the armature conductors, I have found it most convenient to proceed in the following manner: I construct a ring of hard bronze of the required size. This ring and the rim of the wheel are provided with the proper number of pins, and both fastened upon a plate. The armature conductors being wound, the pins are cut off and the ends of the conductors fastened by two rings which screw to the bronze ring and the rim of the wheel respectively. The whole may then be taken off and forms a solid structure.

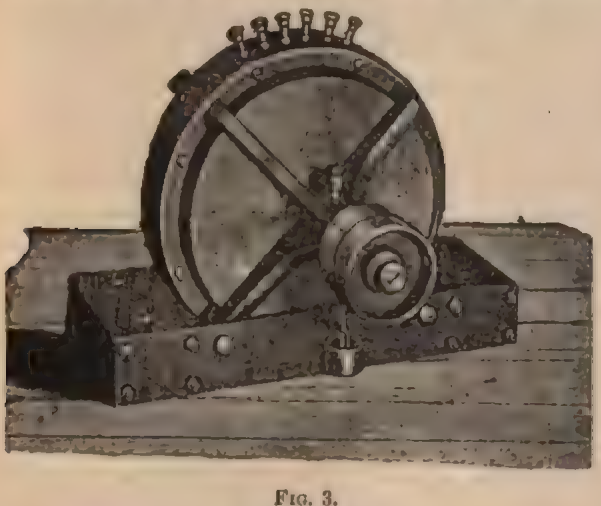

Fig. 3.

The conductors in such a type of machine should consist of sheet copper, the thickness of which, of course, depends on the thickness of the pole projections; or else twisted thin wires should be employed.

Fig. 3 is a smaller machine, in many respects similar to the former, only here the armature conductors and the exciting coil are kept stationary, while only a block of wrought iron is revolved.

It would be uselessly lengthening this description were I to dwell more on the details of construction of these machines. Besides, they have been described somewhat more elaborately in the N.Y. *Electrical Engineer* of March 18, 1891. I deem it well, however, to call the attention of the investigator to two things, the importance of which, though self-evident, he is nevertheless apt to underestimate; namely, to the local action in the conductors, which must be carefully avoided, and to the clearance, which must be small. I may add, that since it is desirable to use very high peripheral speeds, the armature should be of very large diameter in order to avoid impracticable belt speeds. Of the several types of these machines which have been constructed by me, I have found that the type illustrated in Fig. 1 caused me the least trouble in construction, as well as in maintenance, and, on the whole, it has been a good experimental machine.

In operating an induction coil with very rapidly alternating currents, among the first luminous phenomena noticed are naturally those presented by the high-tension

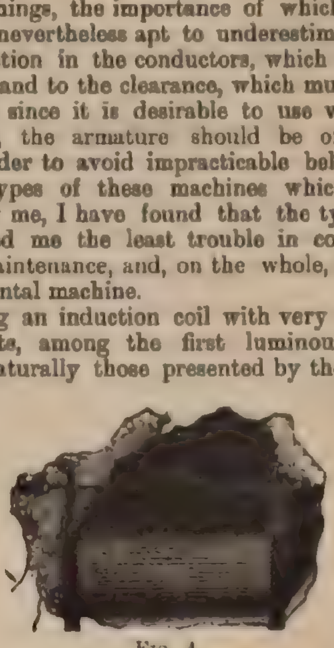

Fig. 4.

discharge. As the number of alternations per second is increased, or as—the number being high—the current through the primary is varied, the discharge gradually changes in appearance. It would be difficult to describe the minor changes which occur, and the conditions which bring them about, but one may note five distinct forms of the discharge.

First, one may observe a weak, sensitive discharge in the form of a thin, feeble coloured thread, Fig. 4. It always occurs when, the number of alternations per second being high, the current through the primary is very small. In spite of the excessively small current, the rate of change is great, and the difference of potential at the terminals of the secondary is therefore considerable, so that the arc is established at great distance; but the quantity of "electricity" set in motion is insignificant, barely sufficient to maintain a thin, threadlike arc. It is excessively sensitive and may be made so to such a degree that the mere act of breathing near the coil will affect it, and unless it is perfectly well protected from currents of air, it wriggles around constantly. Nevertheless, it is in this form excessively persistent, and when the terminals are approached to, say, one-third of the striking distance, it can be blown out only with difficulty. This exceptional persistency, when short,

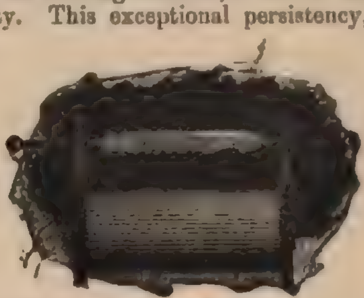

Fig. 5.

is largely due to the arc being excessively thin; presenting, therefore, a very small surface to the blast. Its great sensitiveness, when very long, is probably due to the motion of the particles of dust suspended in the air.

When the current through the primary is increased, the discharge gets broader and stronger, and the effect of the capacity of the coil becomes visible until, finally, under proper conditions, a white flaming arc, Fig. 5, often as thick as one's finger, and striking across the whole coil, is produced. It develops remarkable heat, and may be further characterised by the absence of the high note which accompanies the less powerful discharges. To take a shock from the coil under these conditions would not be advisable, although under different conditions, the potential being much higher, a shock from the coil may be taken with impunity.

(To be continued.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VI. inclusive, new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, ilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we [illegible] them, believing that they will get full value for their mone[illegible]

[illegible] ones of [illegible] on requ[illegible]

SUB-STATIONS.

Although many thousands of lamps are in d[illegible] use, and although many installations—public a[nd] private—are in full working order, it is extreme[ly] difficult to obtain accurate information as to [illegible] On every hand there seems to be the feeling, [illegible] have had to pay for our experience, and you m[ust] not expect to benefit by that experience. Month after month rolls on, balance-sheets are ransacked for information that is carefully hidden, and the public gets no wiser. Here and there public bodies are compelled to give a certain amount of information but this is very meagre and far from as full or complete as we should like. Take Bradford, for example. We know the system employed. We know something as to the electric energy consumed. We know also that the loss upon the installation has been and is a constantly decreasing loss, but, as yet, the installation does not pay. In a short time, perhaps, when the extension is carried out, and extra lights are put on, both ends will meet, and then we shall know the approximate number of consumers and lamps required under certain conditions to make a municipal installation pay. So far as estimates are concerned all projected installations will pay, and will pay handsomely. No one, except he be connected with the gas journals, can safely say they won't. Mr. Preece has been taken severely to task because he insists that the electric light is the poor man's light. We have always contended that the comparison of cost directly with gas or oil is fallacious. There are many economies effected by the use of the electric light which ought to be considered. Be that as it may, however, Mr. J. E. H. Gordon has taken up and maintains he has solved another question that brings the electric light within the reach of the poor man. We are not sure that Mr. Gordon can be allowed to claim the idea of sub-stations, but he has undoubtedly paid a great deal of attention to the subject and if we mistake not, his plans for the lighting of Cambridge, and also for the lighting of Dublin included the use of sub-stations. Putting aside Mr. Crompton's views for the moment, and admitting the best method of town lighting is by generating at a high pressure at a point where labour and power are cheap, where rent and rates are low, and transmitting under the high pressure to the point where the electric energy is wanted, and then transferring down to the pressure required—is it best to have a transformer in every house, or to have a transformer for a block of houses? The whole question is one of pure calculation, and in the majority of cases undoubtedly the proper plan is to transform for a block of houses. This leads to a network of purely distributing mains, which network can be fed at certain points by the transformers, so that the current density and pressure in the network is the same throughout. Mr. Gordon maintains that it does not pay to put in a transformer for much less than 20 lamps, while numbers of small householders never require more than three or four gas jets, and

similarly only require three or four lamps. From a network these small consumers can be supplied as economically as the larger consumers can with their own transformers. Will the small consumers patronise the light? is a question that has yet to be answered. We think they will, and Messrs. Gordon and Co.'s experience at Carlow will be watched with some interest to see if the surmise is correct.

THE LATE WILLOUGHBY SMITH.

It is with deep and sincere regret that we have to record the death of Mr. Willoughby Smith. A short time since we chronicled the death of David Brooks, an American telegraphic pioneer. Now one of our own pioneers has gone, thinning the meagre ranks of those whose exertions and energy made submarine telegraphy practical. Quite recently, too, our late friend completed and issued his monograph on the development of cable work. Before briefly sketching his career we may be permitted to speak of the man as a friend. After all, there is a something which appeals forcibly to older men—casting a glamour upon those good old days when, younger and more vigorous, they were pushing ahead in their career, surrounded by congenial companions, whose faces as time rolls on are seen less and less frequently, till they enter the great unknown. Among a small crowd of young men Willoughby Smith was not the least prominent. His friendship was not given hastily, but when given it was that of a "friend in need." His principle was to speak of men, and act towards them, as he found them, and not from hearsay would he withdraw one atom of the confidence he reposed in his friend. True as steel, gentle, and considerate, though never permitting an imposition, he gradually passed, as we say, into the front rank of those connected with cable work. As long ago as 1848 Willoughby Smith entered the service of the Gutta Percha Company, and soon after this date the Gutta Percha Company commenced experimenting with a view to covering iron or copper wires with guttapercha for telegraphic or other electric purposes. In 1849 they had so far succeeded with these experiments that they undertook to supply 30 miles of copper wire covered with a thick coating of guttapercha, to be laid from Dover to Calais, with a view to practically demonstrating the feasibility of submarine telegraphy. During the years 1849-50 Mr. Smith was busily engaged in the manufacture and laying of this line. The trouble and annoyance caused by the imperfect system of making the joints in the experimental line induced Mr. Smith to give this subject his special attention, and in the cable laid over the same course in the following year (in the manufacture and laying of which he was engaged) he introduced a system of joint making which proved a great success, and in 1855 the present system of joining and insulating the conductor.

From this time onward he was constantly engaged either with cable work or with underground land lines. Early in 1854 the first cable to be laid in the Mediterranean was commenced. Mr. Smith had charge of the electrical department during its manufacture, and assisted Prof. Wheatstone with his experiments on the retardation of signals through this cable, while coiled at the works of Messrs. Glass, Elliott, and Co., East Greenwich. These experiments were made for the purpose of verifying or correcting the results of similar experiments which had been made by Prof. Faraday on lengths of the core of this cable at the Gutta Percha Company's works earlier in the same year. Mr. Smith took charge of the electrical department during the laying of this cable between Spezzia and Corsica, Corsica and Sardinia, and in the following year was similarly employed in the manufacture and laying of a cable between Sardinia and Bona. During the manufacture of this cable Dr. Whitehouse made experiments with it to obtain trustworthy data for giving suitable proportions for the core of an Atlantic cable which was then in contemplation. On Mr. Smith's return from this expedition he remained at home as electrician and manager of the wire department at the Gutta Percha Works, and at once commenced to prepare for the manufacture of 2,500 miles of core for a cable which was to be laid from Ireland to Newfoundland. In 1851, after the manufacture of the single-covered copper wire already referred to as having been laid from Dover to Calais, it was thought advisable to apply the guttapercha in two or more thin, instead of one thick covering, and to ensure adhesion between these separate coverings coal-tar naphtha was employed. But time showed that so strong a solvent of guttapercha was very prejudicial to its durability, and in 1858 Mr. Willoughby Smith invented an insulating and adhesive compound suitable for application between each covering of the guttapercha, instead of the coal-tar naphtha. This compound was soon adopted, and is in general use at the present time. In 1864 the works of Messrs. Glass, Elliot, and Co., at Greenwich, and the Gutta Percha Company, were formed into "The Telegraph Construction and Maintenance Company," Mr. Smith retaining his position at the Gutta Percha Works. In 1865 the late Sir Richard Glass, the then managing director of the Telegraph Construction and Maintenance Company, requested Mr. Smith to accompany the "Great Eastern," and render assistance, if necessary, in the laying of the cable from Ireland to Newfoundland. Early in 1866 Mr. Smith was appointed chief electrician to the Telegraph Construction and Maintenance Company, and in that capacity was engaged on board the "Great Eastern" during the successful laying of the cable from Ireland to Newfoundland, and the recovery and completion of the cable lost the previous year. Mr. Smith's new system was adopted on that occasion. On the completion of the cables, Mr. Smith applied his system to their working, and before he left the station at Heart's Content to return home in the "Great Eastern," he had the pleasure of seeing a speed of 13 words per minute obtained on each cable.

Subsequently, Mr. Willoughby Smith took charge of the French Atlantic cable expedition. The cable was successfully laid, but the strain had been too great, and the chief electrician was for some time incapacitated from work. After his recovery he experimented upon and improved the manufacture of guttapercha for cable work. But is not his life-long work well set forth in his recently published book? and to it our readers should turn to see what progress was made in one industry during a lifetime. Mr. Willoughby Smith was a fairly prolific writer, contributing to periodical literature, and to the *Journal* of the Institution of Telegraph Engineers, of which he was president in 1882-3. It was not till after about 40 years of active service that Mr. Smith severed his connection with cable work.

His remains were interred at the Highgate Cemetery on Wednesday, in the presence of a large number of friends. The Institution in which he had taken so great an interest was represented by Prof. W. Crookes, F.R.S., president; Prof. Cary-Foster, F.R.S., vice-president; and Mr. F. H. Webb, secretary.

CREOSOTING TIMBER.*

BY E. J. SILCOCK, A.M.I.C.E., F.G.S., BOROUGH ENGINEER, KING'S LYNN.

(Concluded from page 55.)

Boulton's process is an improvement in another direction. Having extracted a large portion of the sap in the shape of steam, there is not such a large quantity of albumenoid matter to coagulate, so that the quantity of tar acids may be reduced, and oils of an inferior quality may be used without decreasing the efficiency of the treatment. This is important, as the tar acids are now very largely extracted from the creosote oils for other commercial purposes, and with ordinary London oils the percentage of tar acids is not as high as prudence would dictate if all the sap in young timber is left in. The plant required for Blythe's process

* Paper read before the London meeting of the Association of Municipal and County Engineers.

is somewhat similar to Bethell's, except that no air pump is provided, and a steam injector replaces the pressure pump.

Blythe's process, known as "thermo-carbolisation," differs, however, in principle from Bethell's and Boulton's. The oils in this system are applied first in a gaseous or finely-divided state, and subsequently as a liquid. The process is carried out as follows: The timber is stacked in a closed cylinder, and superheated steam, at a temperature of 800deg. F., is supplied to the injector. The injector delivers into the bottom of the cylinder and draws its supply of oils from a tank. There is also a pipe connecting the top of the cylinder with the injector, so arranged that the injector exhausts the gases from the top of the cylinder, and re-delivers them, along with fresh supplies of finely-divided oil, at the bottom of the cylinder. In this manner a continuous circulation of gases is kept up for 30 minutes or longer, the temperature of the gases varying from 80deg. to 90deg. F. at the commencement, to above 212deg. F. The steam is then turned off, and the cylinder and contents allowed to cool. If the timber is required for joinery or building purposes, the process stops at this point; if, on the other hand, the timber is required for underground or hydraulic works the cylinder is connected with the creosote tanks, and oils are pumped in by steam pressure or ordinary pumps, as in Bethell's process. The author has had no practical experience of this system, but it is claimed that it dries, hardens, and protects timber, the oils penetrating the heart as well as the sap wood. The system is used by the Great Northern Railway Company, whose engineer states that the results produced are similar to those obtained by Bethell's process. It is difficult to see by what means the effects claimed are obtained. Circulating steam at a temperature of 90deg. to 212deg. F. around timber cannot, one would imagine, have a very drying effect, and as the boiling points of carbolic acid and naphthalene are 360deg. F. and 422deg. F. respectively, these bodies, to say nothing of the heavier constituents of creosote, cannot be in a gaseous state at all, although they may be in a very finely-divided state, and so penetrate the pores of the timber. Probably the most effective part of the system is the pumping in of creosote in the liquid state, as in the older processes. All timber should be inspected before treatment as it is practically impossible to judge of the quality of the timber afterwards; and a rigid system of inspection should be enforced to see that the provisions of the specification are carried out, for, except in the case of small scantlings treated by Bethell's process, which can be weighed before and after treatment, there is no method of checking the quantity of oils injected, except by an inspector being present during treatment, and himself gauging the quantity of oil absorbed. As far as practicable, timbers of similar scantlings should be treated at the same charge—*e.g.*, 12in. square timbers and 2in. planking should not be treated at the same operation, or the planks will absorb more than their share of oil, and instead of the large timber getting the specified quantity of oil, it will be robbed by the planking. It need hardly be pointed out that all carpentering operations performed on the timber after treatment militate against the success of the process, and, by breaking through the crust of creosoted fibres, points of access for air, water, and micro organisms are made. It is therefore desirable, as far as possible, to prepare the timber before treatment, and such structures as gates, troughs, etc., which can be introduced bodily into the pressure cylinder should be treated after completion. Where this cannot be done all mortises and tenons, and other places where the uncreosoted parts of the timber are exposed, should be paid with coal tar before the joints are made.

Timber which is intended to resist marine insects is, where practicable, better employed in the round state, because the sap wood more readily absorbs the creosote than the heart wood, and this forms an armour against the worm. The author submits for inspection a few specimens of timber [illegible] by the different processes, to show the depth [illegible]hthalene and the heavier oils [illegible] It [illegible] that sa[illegible] wood absorbs [illegible] mo[illegible] [illegible]art w[illegible] [illegible]od [illegible] [illegible]d by the open tank process, the timber having been imm[illegible] for about a fortnight.

No. 2 is part of a section of a 12in. by 12in. Memel [illegible] treated by Bethell's process, with one gallon of oil per c[illegible] foot.

No. 3 is a section of a Memel plank 11in. by 4in. [illegible]larly treated.

No. 4 is a section of a 12in. by 3in. red wood pl[illegible] creosoted by the same process, but with 7lb. of oil [illegible] cubic foot.

No. 5 is a section cut from the centre of a Ba[illegible] sleeper, 10in. by 5in., treated by Boulton's process, w[illegible] 7lb. of oil per cubic foot.

No. 6 is a section of a similar sleeper, treated by the sa[illegible] process, but one gallon of oil per cubic foot has be[illegible] injected.

No. 7 is a section of a sleeper, treated by Bethe[illegible] process, which absorbed creosote at the rate of 23½lb. p[illegible] cubic foot.

In conclusion, the author submits the following a[illegible] standard specification.

The whole of the timber used must be creosoted w[illegible] coal-tar creosote, which shall be completely fluid at 100d[illegible] F., shall yield 5 per cent. of tar acids, and contain 25 p[illegible] cent. of constituents which do not distil under 535deg. [illegible] The creosoting must be carried out in the following mann[illegible] The timber must be placed in a closed iron cylinder fi[illegible] with a dome, an air pump, and a pressure pump, [illegible] capable of being heated. As much creosote must b[illegible] admitted to the cylinder as will nearly fill it; the te[illegible]perature of the oil must then be raised to over 212deg. F. and the air pump put to work until all moisture in the shape of steam has been exhausted. The cylinder must then be completely filled with creosote, and the pressure pump worked until a pressure of 100lb. per square inch [illegible] produced, and the timber has taken up creosote at the rate of one gallon per cubic foot.

THE ELECTRIC TRANSMISSION OF POWER.*

BY GISBERT KAPP.

Lecture II.—Fundamental Principles.

The fundamental principle on which the electric transmissi[illegible] of power depends is that peculiar, and, I might almost sa[illegible] mysterious interaction between magnets and currents, whi[illegible] we comprise under the name electromagnetic induction, [illegible] more particularly two special cases of electromagnetic inductio[illegible] the one discovered by Oersted and the other by Farad[illegible] Oersted discovered that, under certain conditions, a compa[illegible] needle is deflected by an electric current, and Farad[illegible] discovered that relative motion between a magnet and a clos[illegible] conductor will, under certain conditions, produce a current [illegible] short duration in the conductor. Oersted's effect is a permane[illegible] one; the needle remains deflected as long as the current flow[illegible] Faraday's effect is transient; the current flows, not as long a[illegible] the magnet is present, but only during the time that it takes t[illegible] change the relative position of magnet and closed conductor.

It is clear that, in Oersted's experiment, the movement o[illegible] the needle is due to the action of a mechanical force betwee[illegible] the magnet and the coil. In Faraday's experiment the transient current must be caused by a transient E.M.F., and this, in its turn, is caused by the relative movement between the coil and magnet. The modern method of explaining these things is based on the conception of magnetic lines of force, and the looping of these lines with the wire coil through which the current flows. The whole subject has been so admirably laid before this society in the Cantor Lectures on the Dynamo, which Prof. S. P. Thompson delivered here in 1882, that I need not occupy time by going over the same ground again, but may take it for granted that you are familiar with the lines of force theory. In modern language we may therefore explain the two fundamental phenomena somewhat as follows:

1. The looping of a current with magnetic lines of force sets up a mechanical force between the conductor and magnet (or its equivalent).
2. Relative movement between a magnet (or its equivalent) and a wire coil sets up in the latter an E.M.F.

It follows immediately from these two propositions that looping and movement combined will require the expenditure of power, or yield power, accordingly as the movement is opposed to or in the direction of the mechanical force produced

* Cantor lectures delivered before the Society of Arts.

by the looping. In other words, that we can, by these simple means, convert mechanical into electrical power, or electrical into mechanical power. If we carry out both processes at the same time—that is, if we combine Faraday's with Oersted's experiment—we require, of course, a pair of wires between the two converting instruments. In Faraday's experiment, if we thrust the steel magnet into the wire coil, we expend mechanical power, which is converted into the electrical power represented by a current flowing under a certain, though in this case very small, potential difference. The power represented by this current is again reconverted in Oersted's experiment into mechanical power, which is used to produce the deflection of the magnet. The total amount of power thus transmitted from one place to another is, of course, exceedingly small, but the same principle, applied on a larger scale, effects the transmission of many horse-powers, and it will be my task to show you how this is done in practice.

Before entering upon this subject I must explain an expression used, in stating the fundamental principles on which the electric transmission of power is based. I said that we require a coil and a magnet "or its equivalent." The equivalent of a magnet is, as you know, a coil through which a current flows, and the experiments ought therefore also to succeed if instead of the magnet we use such a coil. In practical work we use neither a steel magnet nor a coil alone, but a combination of a coil with an iron core constituting what is known as an electromagnet.

You know that according to our modern conception of magnetic fields, there emanates from each pole of a magnet a certain flow of lines of force; and when we thrust a magnet into a coil we cause the individual wires of the coil to cut through the lines of force. The quicker the movement—that is to say, the more lines of force are cut by each wire in unit time—the greater is the E.M.F. produced; and the more wires are contained in the coil the greater is the E.M.F. produced, since the E.M.F. impulses of the different convolutions are added. It is also easily seen by experiment that the stronger the magnet the greater will be the E.M.F.; so that we find that the E.M.F. is proportional to the product of strength of field, speed of cutting, and length of conductor. Denoting these quantities respectively by H, v, and l, the E.M.F. produced is in C.G.S. units $H\,v\,l$, and remembering that a hundred million C.G.S. units of E.M.F. are equivalent to one volt, we have the E.M.F. in volts given by the expression

$$\text{Volts} = H\,v\,l\,10^{-8},$$

In this formula the strength of field is given in lines per square centimetre and speed and length are given in centimetres.

The mechanical force experienced by a conductor in the neighbourhood of a magnet pole is, according to our modern views, due to the fact that the conductor is laid across the lines of force emanating from the magnet pole. The force in dynes is given by the product, $H\,c\,l$, c being the current. Since there are 981,000 dynes required to represent the force of one kilogramme, and since the C.G.S. unit of current is 10 amperes, we have the force produced by a current of c amperes—

$$\text{Kilogrammes} = \frac{H\,c\,l}{9{,}810{,}000}$$

These are the two fundamental equations required in the design of plant for the electric transmission of power. Now let us see what is the most simple kind of plant we could possibly employ. At the generating station we require a conductor cutting lines of force; this conductor must be joined by wires with a similar conductor at the receiving station. The second conductor is also laid across lines of force, so that when a current passes it will be acted upon by a mechanical force displacing it parallel to itself and doing work. The arrangement here described is shown in Fig. 1, where the lines R

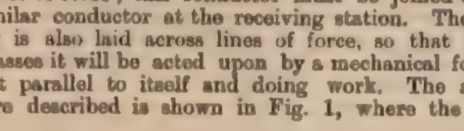

Fig. 1.

represent fixed, horizontal, parallel rails, across which are laid sliding rails or sliders, S_1 S_2. Imagine the magnetic lines of force passing vertically between the fixed rails, then, if we displace the slider, S_1, an E.M.F. will be set up in it, causing a current to flow through the connecting wires, W, and the slider, S_2, at the receiving station. The slider, S_2, is supposed to be laid across lines of force, and will, therefore, be acted upon by a mechanical force. Thus, power may be electrically transmitted from the slider S_1 to the slider S_2. It will immediately occur to you that the experiment I have here illustrated could easily be tried by means of any railway. The fixed conductors and connecting wires would be the rails; the generating slider would be a crowbar thrown across them, and hauled along by a train; and the lines of force would be supplied by the vertical component of terrestrial magnetism. At another part of the railway—possibly miles away—another crowbar thrown across the rails should then be set in motion by the current passing through it. Theoretically, such an arrangement represents correctly enough the electric transmission of power; but I need hardly tell you that it would not work in practice. If you apply the E.M.F. formula I have given to this case, you will find that even if the slider is hauled along at the speed of an express train, there will only be generated about the one-thousandth part of a volt, the reason being that the magnetic field provided for us by nature is so extremely weak. If we could apply an artificial magnetic field of the strength generally employed in dynamo machines—that is, about 10,000 times as strong as the vertical component of terrestrial magnetism—then we could get about 10 volts in our slider. Now, it is obvious that we cannot spread so strong a field over miles of railway, and we must therefore alter our arrangement. This may be done as indicated in Fig. 2, where

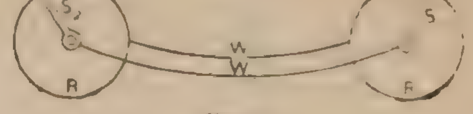

Fig. 2.

one of the rails has been replaced by a centre contact, and the other by a circular conductor. The slider, instead of being moved parallel to itself, must now revolve round the centre contact, which can easily be done by a belt and pulley. We have thus arrived at what is known as a non-polar dynamo. But even this arrangement, although very much better than the progressive slider, is not of practical value for power transmission, because the E.M.F. of non-polar dynamos is still too low. It is only a few volts, whereas we require hundreds, or even thousands, of volts to carry the current to any distance. The obvious remedy is to use a large number of revolving sliders, so connected that the E.M.F. generated in each shall be added; in other words, instead of a non-polar dynamo, we must use an ordinary continuous-current dynamo, wound for high E.M.F. This arrangement is shown in Fig. 3, where G_1 is the generator and G_2 the motor or receiving dynamo. If you connect their brushes, as show in the diagram, and rotate the armature of the generator, a current flows through it, the line wire, W, and through the armature of the motor, and exerts upon the latter a mechanical force, tending to produce rotation

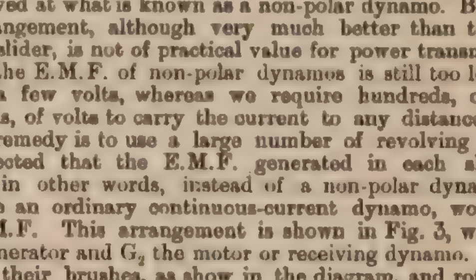

Fig. 3.

and give off mechanical power. I am able to show you this experimentally, by means of two dynamos connected, as shown in Fig. 3.

The Machines Employed in Power Transmission.

This experiment has shown how power may be transmitted electrically. Let us now consider somewhat more in detail the different parts of the transmitting plant. At one end of the line of transmission we have the generating dynamo, at the other we have the motor dynamo, and then we have the line itself, consisting of two wires insulated from each other and from earth. You will readily see that although for the convenience of experimental illustration I have placed the generator and motor close together, this proximity was not an essential condition of the experiment. The motor might have been placed in another room, or in a different part of London, and still the experiment would have succeeded, provided I had used sufficiently stout and well-insulated connecting wires. But then you could not have had ocular demonstration of the fact that movement of the generator armature is closely followed by a corresponding movement of the motor armature.

A full treatment of my subject would of course include a complete investigation of the dynamo, but this I shall not attempt. In the first place there is no time for it, and in the second place it is hardly necessary, since you are all more or less acquainted with these machines. I shall, therefore, not occupy time by giving mathematical proofs for the few formulæ

...ne than in the other; but these are ...ill not be worth while to devote ... As a rule a good generator ...quire to do is to set the ...l line in the former, and ...tter. Now let us see what ... putting up a transmission

... the generating end of the line we want as high an M.F., as we can get, because a high E.M.F. means large power d small percentage loss due to line resistance. At the motor d we want as large a torque or statical effort as possible, com-ned with a certain speed. But a glance at the formulæ will ow that it is impossible to get speed without also getting M.F., which, in the case of the motor, must oppose the rrent, and thus the current actually flowing through the otor is that due to the difference between the E.M.F. of e generator and the counter E.M.F. of the motor. This ference divided by the total resistance of the circuit gives the rrent.

The electrical power developed in the generator is the product this current, and the E.M.F. in its armature. The electrical wer converted by the motor is the product of the same current d the counter E.M.F. of its armature. It therefore follows t the electrical efficiency of the whole system is given by ratio between the generator and motor E.M.F. The more rly alike these two are—that is to say, the less E.M.F. lost resistance—the greater will be the electric efficiency. w the smaller the current the less E.M.F. is lost in resist-e, but to get power with a small current we must work at h pressure, and we thus find that from the point of w of electrical efficiency only, the higher the voltage the ter.

There are, however, other things to be considered besides ctrical efficiency, and if we take due account of these we find t for every case there is one particular voltage at which it is t to work.

Upon this subject I shall enter presently, but before doing so must place before you some points in connection with the ulation of speed and power in transmission plants. Unless can control the speed and regulate the power given out at receiving end of the line, the most perfect motor or the st efficient system is useless. Fortunately, however, electricity not only a powerful transmitting agent, but also one that can easily controlled, and my next task is to show you how this ntrol is effected.

What we generally desire to get in practice is a constant ed of the motor, whatever may be the mechanical power en out of it at any moment. This condition is the same as t required from a good steam engine or other well-governed me mover. The construction of the motor to comply with s requirement depends, of course, on the condition of pply.

We can imagine a large variety of cases, but from a practical nt of view I need only consider two—namely, supply at stant pressure such as we get, or ought to get, from mains nected with a central electric light station, and supply of rent at constant or variable pressure from a generator erected cially for the purpose, the regulation of current and pressure ng automatic. The latter case is that more particularly met h in long-distance transmission of large powers, the former case referring rather to the distribution of small parcels of ver over short distances from a central station. I will take s first.

We have, then, these supply conditions—pressure at the minals of the motor constant, current variable, according to call for power. Let, in the diagram Fig. 4, the curve F

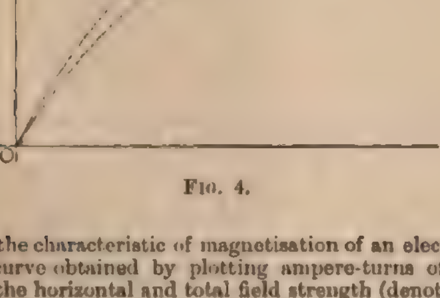

Fig. 4.

resent the characteristic of magnetisation of an electromotor, t is, a curve obtained by plotting ampere-turns of exciting ver on the horizontal and total field strength (denoted in the mulæ by F or Z) on the vertical. If the motor is series wound see that the larger the current the stronger will be its field, by referring to the E.M.F. formula you will find that if the d is to remain constant the counter E.M.F. must increase in the same ratio as the field strength increases. But the counter E.M.F. must under all circumstances be smaller than the supply E.M.F. by just the amount required to overcome the resistance of the circuit through the motor, and this difference is of course proportional to the current. To satisfy the supply condition the counter E.M.F. of the motor ought to slightly decrease as the load and with it the current increases, then the speed will keep constant. But this is exactly the opposite of what the motor requires. Say the machine is running at a certain speed, and giving out a certain amount of mechanical power. Now increase the load. The immediate consequence will be that the speed is slightly decreased, the counter E.M.F. is slightly decreased, and the current is increased. This will immediately strengthen the field, and thus raise the counter E.M.F. again; this will check the current, produce a further drop in speed, and so the reaction will go on until a new stable condition of working is reached at a larger current and lower speed. If we take the load off, the same reaction takes place, only in the opposite sense, and the speed may become dangerously high. What I have here described happens, of course, only if the machine is worked on the rising part of the E.M.F. characteristic E, the part which we would naturally select for economical working. If we over-excite the field magnets—that is, if we employ a great deal more field wire than necessary—then we can work the machine on the drooping part of the characteristic shown by a dotted line in the diagram and obtain approximately constant speed between certain limits, but the machine will still be liable to race as soon as we throw the load off completely. We thus find that a series-wound motor is certainly not suitable for our purpose.

(*To be continued.*)

RECENT DEVELOPMENTS OF ELECTRICITY.*

BY R. L. MURRAY.

What strikes one most when travelling is the enormous rapidity with which applications of electricity have increased—both in number and extent—during the very few years there has been any progress at all.

Some years ago I read a paper upon visual telegraphy before an electrical society, and when prepared it was much struck by the small advance telegraphy had made from the earliest ages until very recent times. It seemed that so long as signalling was only required for military purposes, the system which was sufficient for the requirements of Alexander of Macedon was also good enough for Napoleon Buonaparte. Beacon fires, by which (as is described in the Agamemnon of Eschylus) the news of the fall of Troy was telegraphed to Greece, were also the means used in England to announce the approach of the Spanish Armada, and the semaphore methods, which were almost the only kinds of signals employed until electricity was made use of, were as well known and as widely used in the wars of the Greeks and Romans as in those of European nations at the time of the Battle of Waterloo. Indeed, so wedded were the military authorities in England to the sema-phores, that when they were asked to consider the merits of an electric telegraph they declined to do so on the grounds that nothing better than what they were using was wanted. Even instruments for signalling by means of sun flashes, though they (in the form of helio-graphs) have been recently adopted for use in the English army and have been considered by most people quite a modern invention, were known and used by the ancients. Indeed it would appear as if there was very little new. The idea of the phonograph must have been thought of hundreds of years before Edison produced the one which has made his name famous, if one may judge from the description of an ancient invention, which I had shown me in New York. It was an extract from an old journal and contained in quaint language a description of an apparatus consisting of wheels and cranks so arranged that anything spoken into it would be recorded, and could be reproduced.

When electricity was applied to telegraphy, and when telegraphy began to be used for commercial purposes, immense and rapid strides took place. Still, the first electric telegraph by which the wondrous feat of communicating directly and instantaneously with people far out of sight and hearing was performed, was a very crude and imperfect apparatus compared with the syphon recorders, and such like instruments now in use for the same purpose.

I think I never realised the great developments, and the rapidity with which they were made, until I walked through the South Kensington Museum last year, and looked over the varied assort-ment of telegraphic apparatus stored there. Specimens of the first electric telegraph—Ronalds's frictional machine, bearing the date 1820; Schilling's needle telegraph, of 1830; Cook and Wheatstone's first needle telegraph which required five line wires, and other similar ones of different makers—all showing progress, but all vastly inferior to instruments worked upon the same principle now. Then Bright's bell telegraph—various A B C telegraphs. The first Wheatstone automatic instrument;

* Paper read before the Victorian Institute of Engineers, June 3, 1891.

the chemical telegraphs of Bakewell, Wheatstone, Bain, and others, which were designed to enable a person's own handwriting to be recorded at a place far distant from where it was being written; many step-by-step printing telegraphs of various makers, amongst whom the names of Brett, Hughes, Henley, Siemens, and Theiler, brought before my mind the scientists to whom we are so much indebted. Finally, the original Morse dot-and-dash instrument, the simplest and most reliable of all, and which in its much improved form has outlived all others for ordinary telegraphing, and is almost universally used. At the museum, too, are specimens of different kinds of electrical instruments used for railway signalling, also those used for working on long submarine cables from the first one of Sir William Thomson's invention, and hundreds of other sorts of signalling instruments by which the history of the art can be traced from the earliest electrical days down to the present. Batteries, too, and electric lighting apparatus are there, as well as many kinds of machines which illustrate the multifarious uses to which electricity has been put. Indeed, after looking round the collection, seeing from what crude contrivances the splendid instruments of to-day have grown in such a short time, and to how many different uses electricity has been and is day by day being put, what numbers of able and learned men are applying their energies to develop the force, and what immense sums of money are engaged in its development, I felt that those who speak of electricity as the force of the future do not go far enough. It is the force of the present as well as the future; the force which not only transmits our telegrams and enables us to speak to each other, though hundreds of miles apart, with our natural voice; but is doing lighting and many kinds of motor work, and is as surely taking the place of gas and steam for such purposes as it has taken the place of semaphores for, practically, all telegraphic work. Applications of electricity to telegraphing, lighting, and motor work were what I looked for while travelling. At least, I meant to look for them, but they were so numerous everywhere that no looking for was needed.

In Germany, France, England, and America I saw, I think, every kind of instrument used for the transmission of messages—the Morse, simplex, duplex, used to send two messages in different directions at the same time; diplex, to send two messages at once in the same direction; quadruplex, to send four messages at the same time; and multiplex, for sending a greater number, usually at the same time, on the same wire.

The line wire in this case is in electrical connection with the revolving arm of the instrument. A wire brush attached to the arm passes over a number of small segments which form the circle surrounding the axle. These segments are grouped together at intervals and connected to different sets of apparatus worked by the operators. As the arm revolves, the brush is successively brought into contact with each group of segments, and each set of apparatus is thus momentarily connected to the line. The distributor at each end of the line is controlled by a vibrating reed driven electrically. The distributors are caused to run synchronously within a small fraction of a second.

I saw one of these instruments working with accuracy between London and Birmingham. I saw at the same place in London one of the Wheatstone automatic instruments transmitting news to Edinburgh and Glasgow at the rate of about 400 words a minute. The several kinds of needle instruments which are still extensively used on railways and on some submarine cables, A B C telegraphs still used on private wires, where a skilled telegraphist is not available, though they are rapidly giving place to telephones, the various printing telegraphs which mark in ordinary printing letters the messages transmitted. The Phelps electromotor telegraph of this class is used extensively in America. Messages are delivered written in ordinary characters by this instrument on a long strip of paper. I saw in France the autograph telegraph, a very ingenious instrument, which transmits the handwriting of the sender of the message, and also transmits simple drawings, so that it is useful to send sketches or to verify signatures.

Then the many kinds of instruments used for block working on railways naturally interested me. I think I saw every kind used, and was pleased to find that there is not one superior to those we have on our own railways. In America I saw one combined with a pneumatic interlocking apparatus, which is simple, effective, and economical. I stood in a signal-box at an important railway junction in New York, and watched the signal man for an hour. The ease with which he moved the semaphore signals, points, etc., and controlled the movements of trains without leaving his seat pleased me very much, and I believe the system will be largely employed in the future. But I think no telegraph instruments have improved so much as those in use on submarine cables. In 1859 I was engaged in the working of the first cable laid across Bass's Straits, between Victoria and Tasmania. How rough and clumsy were the instruments we used compared with those now employed for cable working.

Transmitting signals over a long submarine cable is a very different matter from doing the same thing over a land line of equal length. A cable is in effect a huge condenser, the insulation separating the conducting wires from the outer metallic covering. The signalling current is re... very much therefore, so that signals require to follow eac... slowly to be clearly transmitted ov... needle and mirror, so that a ray of light will shine on the mirror and be reflected back to a scale. The smallest current passing through the coil of wire causes the needle to move, and as the mirror is attached to it, the reflected ray is seen to move along the scale. A positive current throws the reflected spot of light to the left, which is read as a dot of the Morse alphabet. A negative current sends the spot to the right, which is read as a dash of the Morse alphabet; and so, by watching the movements of the spot of light, the receiving operator reads the message sent to him.

Sir Wm. Thomson designed the syphon recorder to meet the objection that the mirror galvanometer left no record. The principle of the recorder is the opposite of that of the galvanometer. In the latter a magnet moves within a fixed coil of wire, whereas in the syphon recorder a light coil of wire moves between the poles of a powerful magnet. The signal currents pass through the suspended coil, which moves to the left or right as the currents are positive or negative. The movements of the coil are communicated by a thread to a fine glass syphon which is continually emitting ink upon a strip of paper which moves under it, so that the ink marks show the movements of the coil, and the marks being to right or left of a centre line on the paper can be read, a mark to the left being a Morse dot, and one to the right a dash. I saw the latest type of syphon recorder at work, and there seems little left to desire in connection with telegraphing over cables, unless it be a method of doing so more rapidly.

I saw many other kinds of special telegraphing apparatus, such as fire alarm and police alarm telegraphs, both of which are considered indispensable in other parts of the world, and very many domestic telegraphs—annunciators, as they are called in America.

In an hotel where I stayed in New York there was fixed in each room a dial, divided into 25 segments, on each of which was written something which the occupant of the room might be supposed to want. I copied a number of these wants, and found them to be "Manager," "Head waiter," "Hat waiter," "Boot-black," "Bell boy," "Barber," "Window man," "Engineer," "Ice," "Messenger boy," "Milk," "Laundress," "More steam," "Letters," "Wash list," "Chambermaid," "Scrub woman," "Coal," "Carriage," "Morning paper," "Fruit," "Breakfast." A milled screw-head, fixed to a pointer, projected through the glass cover of the instrument. One morning I moved the pointer to "Boot-black." In a few seconds it moved on to zero, showing me that my signal had been received, and in about a minute or so a nigger made his appearance armed with all necessaries for giving me a "shine." That hotel I found to have electrical apparatus in all sorts of places. The doors of the water-closets would not close from outside, but directly I stepped inside pressure on the floor closed a circuit, released a catch, and the door was closed by the force of a spring which held it closed, an enamelled disc on the outside showing at the same time the word "engaged." Burglar alarms were fitted to every window. These consisted of a simple clip arranged so that the least movement of the window would press the two pieces of metal together, so closing an electric circuit which rings an alarm bell and actuates an indicator, which shows the room the signal comes from. A key fastened to the clip is arranged to throw the room out of the circuit if the occupant wishes to open the window without ringing the alarm.

In winter the rooms in that hotel are kept warm by steam, and the supply of steam to the pipes is automatically regulated. It was summer time when I was there, so that I did not see the apparatus at work, but the manager told me that it had gone all right for two winters. A thermometer is arranged so that as soon as the temperature reaches the desired point a contact is made which closes an electric circuit, and by means of an electromagnet cuts off the supply of steam. Directly the temperature falls below the limit the apparatus again works and readmits the steam. The arrangement I saw, and which the manager calls a thermostat, consisted of a strip of brass and one of rubber (materials which expand differently under the same degree of heat) riveted together at one end. This composite strip is marked unequally by change of temperature, the two pieces being fixed at one extremity while free at the other. There is an appreciable range of movement at the free end. This enables a contact to be made at any point within that range, while a screw adjustment arranges for the contact to take place at any temperature within desirable limits. The thermostats are, it is said, so sensitive as to respond to the change of a single degree of heat.

Similar thermostats are used as fire alarms, when, of course, they are set not to make contact until exposed to a heat of, say, 120deg. to 160deg. Arrangements are made then for the contact to ring an alarm and actuate an indicator, which shows in which room the excessive heat exists. Sometimes it is arranged that the heat indicator and the burglar alarm shall, when they make contact, also light an incandescent lamp—in the former case in each room in the house, and in the latter in the room only whence the alarm was given.

I did not see this in America, but an English gentleman, resident in Vienna, showed me the way it was done in several large establishments there, and in other German cities.

In all the countries I visited I looked up the telephone systems, which I found very much alike in all. Short distance—that is, in and about cities—most frequently done through cables, laid underground or suspended in the air; while long-distance telephony was in all cases done by means of overhead wires. I spoke from Vienna to Prague, and other cities, the furthest distance about 300 miles. In America I spoke over much greater distances; ...occasion over 600 miles, always quite plainly and without the ...st difficulty. In Europe it was not always easy to get the ...ion I wanted, owing to the fact that I often visited ...ents where the knowledge of English was as limited as

was my knowledge of German or Italian. The consuls everywhere were kind enough to send an interpreter with me to the various electrical places I wished to visit. But talking upon technical matters through an interpreter who knows nothing about the subject talked of is a tedious process, so that I often left a place only half satisfied.

I found that the question of successful telephony was not one of instruments but of wiring; if the wiring is properly carried out—properly as regards the conductivity, the insulation, and taking due precautions against induction, almost any telephone will speak all right. When I was in London, Mr. W. H. Preece, chief electric engineer to the Post Office, showed me the arrangements made in connection with the London to Paris telephone lines. It was thought for a long time that speaking through a submarine cable of the length required, and connected to two land lines, would be practically impossible, but Mr. Preece and his assistants went carefully into calculations, and afterwards experiments, and were convinced that it could be done; and the result has proved them to be right, for communication was completed in March last, and the success of the line has been most pronounced. The land line on the English side is of copper; weighs 400lb. to the mile, has an electrical resistance of 2·25 ohms to the mile. It is supported on wooden poles, fixed 70 yards apart. The going and returning wires are made to spirally twist round each other all the way, the spiral being completed at every fourth pole. The line is 85 miles long. The French land line is similar in construction to the English, but the wire is thicker, being 600lb. weight to the mile. Its length is 204 miles The cable connecting the two land lines contains four separate conductors, two for each circuit. Each conductor is a strand of seven pure copper wires, weighing 160lb. per nautical mile, with a resistance of about 7·5 ohms per mile. It is covered with three alternate layers of Chatterton's compound and guttapercha, weighing 300lb. per mile. The insulated wires are twisted spirally round each other, and then served with tanned hemp, on which is laid a spiral sheathing of 16 galvanised iron wires, each 0·28in. thick—a coating of mineral pitch and sand protects the whole.

The cable was laid without any mishap, though very bad weather was experienced at the English end of the work, and when the joints were made with the two land lines, talking between London and Paris was carried on without the least trouble. I had sent me a very interesting description of the whole work, building the land lines, constructing and laying the cable—from which I have taken the extracts I have given. The tariff of charges has been fixed at 10f. for three minutes' conversation between the two cities. It is just 40 years since the first telegraph cable was laid between England and France. Who then would have thought it possible to live to see one laid, over which (and over nearly 300 miles of land) they would be able to talk as plainly as if the person they were talking to was alongside them?

Wires placed under the sea naturally lead me to speak of underground wires. Electrical engineers and managers like to have their wires where they can see them, and the cost of placing wires underground has caused those who have to find the money to fight against underground systems. There is no doubt, however, that all wires in large cities will before many years are over be underground I was a member of a board appointed by the Government here to enquire into the merits of several plans which had been proposed by local men for placing the wires underground. While engaged in that enquiry I looked up all I could of what had been and what was being done in the same way elsewhere. I carried on my investigations about a year later when preparing a paper on the subject, which I read before the Australasian Association for the Advancement of Science, so that I was fairly well posted up in the subject and had a fair acquaintance with its cost and difficulties. It was somewhat of a surprise to me, therefore, to find that in most of the cities of Europe I visited—as well as in the chief ones of America—underground wiring is going on rapidly. The companies had to face the expenditure, and found it not so very dreadful after all. I don't regard overhead wires as so great a nuisance as some people do. It depends chiefly upon the methods of fixing them. Our street pole system is copied from America. Hardly anywhere else did I see lines of poles in the streets of big cities. The wires (those which are not underground) are usually carried over the roofs of the houses, so that they cannot be seen unless one looks for them. Certainly some of the structures on which they are fixed are very ugly when one does see them. The plan suggested by one of our members, Mr. Seitz, in a scheme he laid before the board I have referred to, has always seemed to me to be subject to less objections than most others I have seen, and I cannot think the cost of it would be prohibitive. It was to make channels directly under the paving stones of the footways, in which cables would be laid connecting with an ornamental pole standing at each street corner. This pole would have a chamber in it where connections could be made between the main wires and wires leading to the houses between the poles. Thus, the main wires would be underground and the distributing wires overhead. The poles could be used as lamp pillars, letter-boxes, and for other purposes.

In America, as most people know, there has been great trouble about overhead wires, and the conclusions come to are that in all cities of more than 125,000 inhabitants wires should go underground, but that if they are allowed to remain overhead they must be fixed in accordance with rules, which prescribe the methods of fixing, the sizes of different kinds of wire used, where they are to be fixed and indeed everything connected with them which experience has shown to be necessary in the interests of safety and efficiency.

In the State of New York and in several other States there are boards of electrical control whose duty it is to see that the rules are carried out. Something of the kind should be done here. Either a board of electrical control for Victoria should be appointed, as in America, or, as in England, a branch of one of the Government Departments should have the duty placed upon it of seeing that proper rules for the fixing and working of electrical wires and apparatus are carried out. The rules which were drawn up by this institute in conjunction with the Fire Underwriters' Association, and which have been enforced by the latter body, have done much good, but they do not go far enough, only dealing with wires which affect the safety from fire of buildings insured by the companies.

When I was in London I had the good fortune to be present at a meeting of the Institution of Electrical Engineers, at which Major Cardew, the electrical inspector for the Board of Trade, read a paper upon "Laws and Rules relating to Electrical Conductors, etc." I also heard the discussion upon the paper, and which was joined in by many of the eminent men who were present, and whose knowledge and experience gave much value to their opinions. I was greatly impressed by what I heard, and before I left London obtained from Major Cardew and Sir Thos. Blomfield (one of the secretaries of the Board of Trade), all the English Acts of Parliament and the Board's rules and regulations, with the intention of placing them at the services of whoever may have the duty placed on them, of drawing up an Act of Parliament and rules for use here. I also had given me by the Mayor of New York and the Electrical Superintendent of the city of Chicago the rules connected with the subject in America, copies of boards of electrical control reports, and other papers of interest.

I saw the underground work carried out in a good many European cities, in London, and in America. The systems vary in accordance with the voltage of current used. If low-pressure only is employed, there is not so much danger of leakage as if currents of high tension are used. In the latter case, therefore, much more care is required to insulate the wires, consequently more expense is entailed. In Rome, very high-class cables are placed in wooden troughs. In Vienna, I saw a very costly plan. A brick in cement channel, lined first with asphalte and then with wood soaked in paraffin, was built about 3ft. below the surface of the street. The channel was 18in. across the bottom, which was flat, and 15in. high, the top being arched, and having a slot through which cables were passed down. Troughs made of wood saturated with paraffin were placed on the floor of the channel, and in them very highly insulated and lead-coated cables were laid. The slot through the roof of the channel had a watertight cover fitted to it, so that every precaution was taken to preserve and protect the cables. I asked the engineer, who showed me one of the channels, if it was not dreadfully expensive, and he said that it certainly cost a good bit, but they thought it paid better to do the work thoroughly at first. I said it was well to be him to have command of money enough, at which he smiled and shrugged his shoulders. It seemed to me, indeed, that the system adopted almost always depended upon the richness of the firm or corporation doing the work.

The greatest undertaking in underground work I saw was the Ferranti cable, to carry current of 10,000 volts pressure from the Deptford station into London, there to be transformed into more moderate pressures for distribution to the company's customers. When I visited the Deptford station, I saw the whole process of making the cable, about two miles of which were being made per week. The process is as follows: Copper tube, about 1in. in diameter and $\frac{1}{8}$in. thick is cut off to a length of 20ft. This is taken to a bench and a sheet of brown paper wound round it. It then goes to the insulating machine, where it has sheets of brown paper previously prepared by being passed slowly through a cauldron full of hot black oil or wax, which soaks thoroughly into the paper, rolled round it as tightly as possible till there is about half an inch of the prepared paper wound on. The insulated tube is then slipped into another copper tube just big enough to receive it, the quantity of copper in this tube being exactly the same as that in the inner tube. Then it is passed through a draw-plate, which squeezes the outer tube very tightly on to the insulation. Then the outer tube is insulated in the same way as the other, and the double tube is then slipped into a protecting case of thin steel tube, in the centre of which a hole is drilled, through which hot wax is forced by a force pump to drive out all air and form a solid mass.

The concentric main thus formed is 20ft. long. The distance from Deptford to the part of London the current is to be taken to is about seven miles, and as there were three mains to be laid down the number of joints was very considerable, and upon the joints being successfully made depended to a very great extent the efficiency of the main. We must remember, too, that the current to be transmitted over it was of 10,000 volts pressure, so that if a weak spot existed it would be found.

After a number of plans for joining the lengths had been experimented with, the following was adopted, and when I was there was said to have proved thoroughly successful: Each length is taken to a lathe, where one end is turned very carefully and smoothly down in a taper of 6in. length from the centre conducting tube back to the outer one. The inside of the inner copper tube is then accurately bored out, and a length of turned copper rod forced into it, so as to make an accurate metallic fit. A sleeve of thin copper tube is then slipped 3in. or so over the end of the outer conductor, which is left bare for the purpose, and is there corrugated down upon it with three corrugations. This corrugating is a very important part of the Ferranti main, as it ensures both good metallic electrical contract and a strong mechanical joint.

The other end of the 20ft. length is treated in a corresponding way to form an exactly opposite contour, into which the end of the next length can be forced tightly; that is, the end is turned out in a hollow coned or taper form from the outside to a length

of 6in. When the ends of two lengths are pushed together, the solid rod which projects from the inner copper tube of one length goes into the inner tube of the other length, and the sleeve on the outer tube of one length slips over the outer tube of the other length, and is corrugated on to it. Before the two ends are brought together a sleeve formed of insulated paper covered with a steel tube is slipped on to one of the lengths, and as soon as the processes I have described are completed, the sleeve is slipped over the joint. Hot wax is then forced in, and each end of the steel jointing-piece is corrugated down upon the steel protecting cover of the two lengths thus joined together. When I was in London there was about a mile of the mains laid down and tested with a current of from 16,000 to 19,000 volts pressure, and so far no breakdown had occurred.

The machinery at the Deptford station corresponds with the mains. When completed there will be six improved Corliss engines, two of 1,500 h.p. each, and four of 6,000 h.p. each. Only the two smaller ones were in position when I visited the station, one of them driving a Ferranti alternator, designed to give current of about 100 amperes at 10,000 volts pressure. The engines in use run at a speed of 65 revolutions per minute, with steam pressure of 180lb. The flywheel is 21ft. in diameter, and 8ft. wide, grooved for 40 driving ropes of 5in. girth. There were 12 Babcock and Wilcox boilers in use, 12 more were just fixed, and 24 more will be in position when the station is complete, giving a total steam power of 24,000 h.p. The dynamo in use has an armature which weighs with its shaft fully 25 tons. It runs at a speed of 160 revolutions a minute. The field magnets of this dynamo weigh about 42 tons.

I thought that machine was a pretty big one, but it is a dwarf compared with the two being constructed, the shaft and framework of which I saw. The shaft alone weighs 27 tons. These monsters are to be driven by two engines, one on each side directly coupled to the armature shaft. The output of each of these dynamos is intended to be 10,000 e.h.p.

Of course, there has been a great deal of talk about the Deptford scheme. The idea of using currents of such pressure is declared to be madness; danger is spoken of, and all sorts of failures prophesied. Time will tell. If the Deptford scheme is a success it will reduce the cost of production of electric light very materially. It is much to be hoped therefore that it will be successful.

There was a great electrical exhibition held in Edinburgh last year, and as the Institute of Electrical Engineers held special meetings there, I timed my visit to the Scotch capital so as to be able to attend the meetings. I was well repaid, for I met there electrical engineers from all parts of the world and had the pleasure of an introduction to a good many of them. Fortunately for me a paper upon the lighting of our last exhibition which I had sent to the institution had been read and discussed not very long before, and I found that as the writer of that, and as an Australian, and a past-president of this institute, I was the object of a good deal of interest. Indeed I never was treated so well, had very many more invitations to visit people than I could possibly accept, and was made much of generally.

Besides discussions upon various interesting exhibits, papers were read; one, by pupils of Profs. Ayrton and Perry, upon secondary batteries being especially valuable, as it showed the strong and the weak points of these very valuable, and as they are beginning to be considered indispensable, parts of an electrical light and power system. The results of the investigations and experiments entered into by the professors and their pupils were very satisfactory, as the secondary batteries were proved to be capable of being used under conditions more varied and severe than was before believed possible, and to give out when properly formed and used a much higher percentage of the energy put into them than had previously been obtained from them. I commend that paper, and the lengthy discussion which took place upon it afterwards in London, to the attention of electrical men. As I said at the Edinburgh meeting, I expect some day, when I get a proper place to form and change secondary batteries, to substitute them for the many handfuls of primary cells I have in use working the railway electrical telegraphs, besides lighting the carriages and doing a lot of work which I believe no other electrical machinery can do so well. I saw secondary batteries used for lighting Chelsea, where they were supplying current to about 3,000 lamps, very satisfactorily to the consumers; and the very obliging manager of the company, who showed me all the details of the system, told me that the directors were quite satisfied with the result from a suppliers' point of view. I saw them used for telephone and telegraph work too, and what I saw confirmed me in the belief that whatever a primary battery can do, a secondary can do much more cheaply, and quite as efficiently, as the best primary battery. Indeed, primary batteries—such as the Schanschieff, and others and better ones—can never be extensively used as sources of electricity. Some years ago, experiment proved that, taking the cost of electric current produced by a dynamo machine as one, that of secondary batteries might be set down as four, and primary batteries as 12. Since that time dynamo machinery and secondary batteries have been made more efficient, but I do not think primary batteries have, so that the difference in value between them is now still greater; and when we remember that some of the ablest investigators in electrical science of the present day are devoting much time to improving secondary batteries, and that they are so capable of being improved, I think we may take it for granted that they will be more and more used, and with always increased satisfaction. Among the exhibits at Edinburgh which the members of the Institution of Electrical Engineers examined closely were three I think I should say a few words about.

1. *Electric launc*[illegible]*fternoon*, by invitation of the gentleman in charge of the launches which ply along the canal [illegible] members, to the number of about 100, made a visit of [illegible] to these launches, and were taken about 12 miles down the [illegible] and back. The launch in which I was was driven by a [illegible] which worked up to $2\frac{1}{2}$ h.p. It was supplied with current fr[illegible] secondary cells, placed under the seats, and ran at the rate of [illegible] miles an hour (its maximum speed being 12) exceedingly [illegible] and pleasantly. The voltmeter showed that the pres[illegible] current was 109 volts, and the man in charge told me that [illegible] voltage was only reduced by six volts after a day's work, in [illegible] case the expenditure of energy was certainly small. The [illegible] men present, some of whom had considerable experiences of [illegible] launches, said that the cost was very little, if any, more [illegible] launches propelled by small steam engines; and I need [illegible] how much cleaner and freer from smell, smoke, and [illegible] annoyances, the electric launches were.

Electric launches should be eminently suitable for [illegible] purposes, for example, to be used instead of steam launche[illegible] warships. No getting up steam; the power is always ready [illegible] occurred to me when reading why the lifeboat did not [illegible] Queenscliff to go the late shipwreck, that electric gear might [illegible] fitted to such boats as an auxiliary power. Two or three [illegible] power might be arranged for and would make all the differ[illegible] in propelling a heavy boat. I notice lately that the Imper[illegible] Government have had an electric pinnace built to convey [illegible] between the Chatham and Sheerness dockyard; her speed is [illegible] knots an hour, and she will carry 40 passengers at a time.

Another of our examining visits was paid to a telpherage [illegible] which was doing work in the neighbourhood, carrying heavy [illegible] for a distance of about a quarter of a mile on a steel wire [illegible] suspended about 20ft. from the ground.

The telpherage system has been defined as "the transmissi[illegible] vehicles by electricity to a distance independently of any con[illegible] exercised from the vehicle."

It is an attempt when using electricity as a motive power [illegible] railways to use a different form of road for the vehicle [illegible] travel on, as well a different form of motor and vehicle.

Prof. Fleeming Jenkin, the designer, said that the idea in [illegible] mind was that by using electricity as the power one or two or [illegible] number of horse-power could be drawn off from different [illegible] a conductor many miles long; it would be of advantage to [illegible] divide the weight to be carried, distributing the load [illegible] many light vehicles following each other in a continuous str[illegible] instead of concentrating the load in heavy trains widely [illegible] apart, so that a cheap, light form of road would be sufficient.

And a cheap light form of road has been adopted, for [illegible] vehicles travel on suspended metal cables, which can cross [illegible] kind of country without bridges, earthworks, etc., being necessar[illegible] No land would require to be purchased, no fences, gate-houses [illegible] any of the other similar expensive adjuncts to railway mak[illegible] would be required. So far only slow speeds have been attained but where high-speed travelling is not necessary, for conveyan[illegible] of goods, for instance, in rocky, mountainous countries, [illegible] coal and other mines, the telpher system seems admirabl[illegible] adapted. The cost, both of construction and maintenance, is [illegible] to be very small as compared even with an ordinary road. The[illegible] is a telpher line at work in Cornwall, too, carrying materials to [illegible] from a mine there, with much satisfaction and economy to [illegible] mine owners. I should say that the metal cable which forms [illegible] road also carries the electricity to the motors which drive [illegible] vehicles.

The gliding railway was another interesting exhibit at Edin[illegible]burgh. It is not electrical, but we visited it nevertheless. It [illegible] based upon two principles: 1. Consists in substituting for [illegible] wheels and axles of ordinary railway carriages slides which gli[illegible] on a thin film of water. 2. Propelling the train by water [illegible] under pressure by means of propellers placed at intervals on [illegible] line, and discharging water horizontally in the direction of [illegible] train into a bucket rack underneath the carriages. The slides [illegible] hollow cast-iron boxes, the bottom part removed, but having [illegible] furrowed margin. The tender carries water under the requisite pressures for supplying the slides, the water being conveyed from the tender by pipes which pass under the carriage.

When the water is admitted into the hollow part of the slide [illegible] naturally seeks to escape, but its exit is impeded by furrows [illegible] the margin of the underside of the slide, and at the same time the air is compressed in the upper part of the slide. When the pressure becomes sufficient to lift the slides the water flows out equally on all sides in a thin film, which raises the slides from the rails, and it is said the resistance to the motion of the train is so slight that the tractive force of 1lb. weight is enough to move a ton. All sorts of things are claimed for the gliding railway, but the engineers I heard speak of it expressed doubts as to its value for various reasons.

We paid a visit also to the Forth Bridge, went over it and under it. It is a monstrous and wonderful structure. I went over the underground railway works—the first electrical railway in London. It was not completed when I was there, but I have within the last few days had a letter from the electrical engineer, who tells me that it is working very satisfactorily indeed, and that many more like it are projected. It is so popular that crowds who want to travel by it can't, and the question of increasing the number of lines is pressing upon the proprietors.

I saw several electric tram systems on the continent of Europe, all giving much satisfaction. One of the engineers of the firm of Siemens Bros. told me that electrical railways were opposed by all sorts of interests. People who are interested in steam motors, in horse trams, farmers who grow horse feed, and dealers who supply it, horse breeders and many others, combine to fight the advance of electric motors for railways. But he said they are the best, and

therefore will survive all others, and are increasing in number slowly but surely. He told me of a great electric railway projected in Russia, some hundreds of miles long, the plans and estimates for which were then before the Czar and his advisers. Also of one which he believed would be gone on between Vienna and Buda-Pesth. European engineers, he said, believed in electricity as a motive power, and financiers were beginning also to believe in it.

Italy is a country we are accustomed to consider as being very poor. I was therefore much struck at the magnitude of the engineering works I saw there. I landed at Brindisi, and travelled by rail thence to Naples *vid* Torento—for about half the distance among the Appenine range of mountains. The railway was for many miles cut through mountains and over great gorges. The train passed out of tunnel after tunnel, joined together by great bridges built over the gorges. I am sure we in this country would not attempt to build such a railway; we would consider its cost prohibitive.

In Rome I found one of the finest electric lighting stations in the world. Money lavished to make everything about it as good as it could be. Indeed, the idea in my mind was that the gas company, to whom it belonged, had a desire to show how expensive electric lighting was. I found, however, that the gas company was so satisfied with the electric lighting that they were arranging for a very much larger station at Tivoli, where is a great water power to be utilised to drive dynamo machines, the current to be carried underground to Rome. In Rome, too, the city authorities were engaged in engineering works; making new streets, and otherwise beautifying, making more convenient and more healthful, and transforming that ancient and eternal city into a modern one.

In other Italian cities I found the same signs of engineering activity, which seemed to me wonderful considering the immense sums of money spent yearly upon naval and military works, and the fact that the immense standing army maintained not only cost so much to maintain, but took so many thousands of men from the ranks of producers.

In America, electricity is everywhere. Every little town has its central station. Arc lamps are to be seen in all the streets, and incandescent lamps in the buildings. Electric trams, too, are very frequent. The mileage of the different kinds of street railways in September of last year was: Horse, 6,043 miles; electric, 2,065 miles; and cable, 501 miles. And day by day the horse systems were, and are being changed to electrical.

In Albany, the State city of New York, I rode in an electric tram which travelled at 12 miles an hour. One part of the route was round a hill, where the curve was considerable, and the gradient 1 in 15. When in New York I met a large number of electrical men from all parts of America. They had come to New York to attend a meeting which is held half-yearly, and at which all kinds of electrical applications are discussed. They all laughed at the idea of any kind of power competing successfully with electricity for all short railways, and even agreed that 10 years would see it applied also on long lines. The use of electricity had given an impetus to underground railways in large cities. New York and Chicago are now seriously contemplating taking their street railways underground. I saw a sketch of one designed for Chicago. Four lines were to be laid, each in a separate tunnel, two to be for an express system and the other two at every street corner.

It is curious when thinking of underground and electrical railways to note that in the *Illustrated London News* of November 10th, 1855, there is a description of a proposed railway to connect England and the Continent under the Straits of Dover, the rails to be laid in iron tubes, the motive power of the railway to be electricity, and the tunnel to be lighted by the same medium.

In America whenever a motive power is wanted electricity is thought of. In mining to transmit power from the top to the bottom of shafts, to crush, haul, and pump, and propel trucks, to break down the products by electrical drills and miners, to light—indeed, to do everything. Fancy a great central plant, dynamos driven by immense engines constructed and worked on the most economical principles, wires led from the dynamos all over the town at any voltage desired, the current transformed at convenient places, and then led about to light the streets and houses, and drive the many kinds of machinery used, not only for propelling tramcars, but driving saws, sewing machines, hair brushes, and the other hundreds of different kinds used in a big city.

I think one of the chief reasons why electrical applications are so popular in America is the fact that they are so much discussed both by journals, and at meetings of societies, "conventions," as they are called. There are very many associations, the members of which meet at more or less frequent intervals, discuss subjects of interest, and have excursions together, and afterwards disseminate in their several centres the information they had gained. People, ladies as well as men, come from all parts of the United States and Canada to attend these meetings, and it is surprising the wide interest taken in them.

At one the following were among the papers read: On Electric Power Tables and Curves, On Primary Batteries, On Photo-Electricity, The Electric Arc, Distribution of Steam from Central Electric Light Stations, Electric Light as used on Railroads, Electric Light Wiring from a Mechanical Standpoint, Underground Conduits, Care of Alternating Currents, Electric Measuring Instruments, Rating the Candle-power of Incandescent Lamps.

I meant to speak of several other electrical matters of interest, including the supply question when using currents of high pressure, the use of transformers, electric meters, and the construction of incandescent lamps, but my notes have already become so long that I must defer doing so to some future occasion, and will conclude by telling you of a visit I paid to a laundry in one of the American cities. I was leaving the next morning, and was told that our washing, the accumulation of two or three weeks, which had been sent out the day before was not yet returned. After making certain enquiries I found that the most sure way to get my shirts, etc., was to go to the laundry for them, which I did accordingly. I found that all the machinery was driven by an electric motor, taking current from the street mains—washing machines, mangling machines, and even ironing machines were electrically worked. The last were in operation and most interested me. They consisted of two hollow cylinders of iron kept hot by means of spirals of wire passing through the inside and which were maintained at a red heat by electric currents. The cylinders rotated slowly, and were kept together by means of spring pressure. Collars were being ironed by being passed twice between the rollers, and the process seemed to answer admirably.

I got my clothes, and had the satisfaction of knowing that if I had not visited the laundry I would have missed seeing the electrical ironing machines, and also would have been detained in the city at considerable inconvenience, or gone away without my shirts.

COMPANIES' MEETINGS.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY

The eighth annual meeting of this Company was held at the Westminster Palace Hotel on Tuesday, the chairman (Mr. J. Staats Forbes) presiding.

The **Secretary** (Major Flood Page) having read the notice convening the meeting, and the report (which with the balance-sheet will be found in our last issue) having been taken as read,

The **Chairman** said: I don't know whether any gentleman has gone through the agreeable exercise I have within the last 24 hours, of reading all the reports from the beginning—that is, in 1884, when the Company began business? We are now dealing with the eighth complete year of the undertaking. I discovered a very singular thing—viz., that all the early reports are what is called very full; there are a great many paragraphs, and they are very long. I have been conversant with the reports of different companies for a good many years, and I find this the characteristic of all these reports—where the dividends are short the report is very long, and *vice versâ*. This seems to indicate that when the company has emerged, as we have done, from mere preliminary difficulties and trials, there is very little to say. It is your acts, not your words, which help you then. How much profit has been made? Well, happily for us, our reports have gradually diminished in length almost as the dividends increased in amount, and this report which is before you to-day is one of the shortest we have ever had, and I hope you think as we do, that it is one of the most satisfactory, because it reveals one or two primary things of some importance—viz., the bulk of the business has increased, and the profit has increased, and we are, happily, enabled to dispense in respect of the year, and of arrears accruing due to the A shareholders, a larger amount than last year or in any preceding year. That is the whole of the story. As I said last year, this class of business—of paying large dividends—is rather a novelty to me, and I have been an apologist for so many reports that I am rather nonplussed when there is nothing to say. The whole story lies in the figures. These joint stock company accounts are not quite so full as those I am in the habit of dealing with, but the essence of them lies in the profit and loss account. Take the first account. On the one side you will see there is income, on the other side the cost of attaining it. I propose to take you through the income in order to compare the year with which we are dealing with the preceding one. Now, take sale of lamps, fittings, royalty on holders, etc., £143,229. 14s. 11d. The corresponding heading last year revealed £118,865. 15s., so that the amount of sales has increased by £24,363. 19s. 10d. The next item is interest, etc., £427. 12s., against £1,442 in the preceding year, a diminution of £1,000 or more, arising from the fact that in the course of the year we realised the bonds of a certain company which paid 4 per cent. interest until we took them over and converted them into money, and of course that affected us. Another item of income is stock on hand. I have had to explain a great many times that we are bound in the very nature of the thing to keep a very large amount of money locked up in stock. There are one or two great types of lamps, the 16 c.p. and some smaller ones, which constitute the mass of our business. But there are a great many lamps of other types, and these are themselves subdivided into types of more or less power, which involves this, that in order to suit the necessities of a great many customers, and the varying conditions of some of them, we are obliged to keep a large supply of lamps on hand or on call. Take this time of the year; these are two of the slackest months of lighting, June and July, but we must have sufficient provision put ready for the darker days of winter. It would not do to postpone the manufacture of lamps until they were wanted. You see what that means. The stocks last year were £56,266, this year they are £59,308. That is a large amount of money to have locked up in any business. I must qualify the amount, however, by saying that a considerable portion of it is not represented by lamps at all, but platinum. We secured a large quantity of it, as I told you last year, at a price which was subsequently greatly exceeded in the market; but we had to find the money for it, and it goes into stock. We have now £15,000 worth of it, and we have a great quantity of manufacturing material which must be in store from time to time.

On the opposite side of the account you will see what the cost of production has been. Dealing with the stock in hand at 1st July, 1890,

you will find that we have somewhat increased it by £3,042. Wages, purchases, etc., are £56,362. 19s. 6d. That represents the manufacturing cost at the factory. "Wages" is one of the things which does not diminish. "Purchases" means the material of which the lamp is formed—glass, platinum, carbons, etc. Then come salaries, Directors' fees, rents, etc., then depreciation on plant, written down, as you see, to an extent of £2,160. 18s. 10d., this being, we think, quite a liberal quantity—a very sufficient and prudent quantity, in excess by about £300 of last year. Then comes the balance. Well, the balance is £72,905. 4s. 7d., as against £61,115 last year. That is the result of the trading of the year. I don't know whether you will consider it a satisfactory result? We think it is. We think that £11,790 more profit in the year is rather a good indication of the value of this business. When you see that the output leaves such a considerable profit as £73,000 (nearly), it is not a bad business, and it enables us to recommend you to pay the 17 per cent. to which you are entitled in preference to the deferred shareholders. We have 117,000 £ deferred shares, and, as you know, for a number of years you had no per cent. at all. We must not live in illusions, nor is it very desirable that the outside world should believe that 17 per cent. is the normal condition of this Company. It may be just as well to know that in 1884 we paid nothing; in 1885 we paid nothing, in 1886 nothing, in 1887 nothing, in 1888 nil—and it was only the confidence which the Directors had in the soundness of the thing, and your confidence in the Directors, which carried them through the difficulties of all those years in the face of nothing to divide. Now that confidence has been justified by the results. Once the patent cases were settled; once the Company was got upon its legs it began to pay. And then, in 1889, for the first time we found it prudent to pay a dividend, and we paid 10 per cent. In 1890 we paid 15, and now we propose to pay 17 per cent. Now, that seems a large dividend, and will no doubt excite the cupidity of some people. But if you will divide what we pay by the years we have been working, you will find it comes to 5·5 per cent. per annum. That is the outcrop of that part of the business. On the other side of the account is the balance-sheet. You see how the debtor side stands. The share capital practically remains intact. It has not altered. We have the same number of £5 shares fully paid up and allotted to the Edison Electric Light Company; the same number of shares to the Swan, the same number of A shares, £3 paid, and the same number of B shares fully paid, the total capital being £471,298. You can see that as regards the first three, they are entitled to 7 per cent. cumulative dividend in preference to the B shares. That is why to-day we propose to divide not only the 7 per cent. in respect to the year, but arrears in respect of those years during which you got no dividend. The first item which admits of comparison is the sundry credit balances—a credit balance in the sense of having to pay it. Last year you owed £26,257. This year you owe £14,706. The volume of our trade has been so much larger that we have been able to work our business and owe less money at the end of the year. At the same time, we have transferred a sum to the reserve fund, which now stands at £12,689, as compared with £4,595 last year. Then comes profit and loss account as per appropriation account. We have thought it prudent to pay arrears, after providing for the 7 per cent. on the current year, in respect of the cumulative preference dividend for 1885 at the rate of 3 per cent., and to pay 7 per cent. on the arrears of cumulative preference dividend for the year ending June 30, 1886. But we have got 1887 and 1888 still remaining as a charge on the future, in respect of which you have had no dividend. Going on to the other side of the account—cost of patents, goodwill, preliminary outlay, loss on working, etc., and further expenditure thereon—£238,064. Now that further expenditure thereon is in respect to payments that cropped up for legal expenses and patents in connection with the founding of the Company. Against that we wrote off amounts in respect of plant out of date and superfluous, forming part of the original price in the amalgamation—that brings the amount down to £234,638. If you cast your eye further down the account, you will see that the amount of B shares issued as *per contra*, is £117,820. This is a mere matter of bookkeeping. Then comes the Manchester Edison-Swan Company, Limited, with 100,000 B shares at £12,000. That is a deferred interest we have got in that company. Whether it will be worth anything or not, time only can reveal. Some day it may be a useful asset. Then you come to the other offsets—freehold property, £45,012; plant and stock, £83,188, as against £77,000 last year. During the year, in anticipation of future work, and in order to meet current pressure, we have been obliged to extend our factory considerably, put up new gas works, and new glass-blowing works, all under the pressure of a growing business. The money you see represented there as £45,000. We bought the property originally very cheap, and I have no hesitation in saying that if that property were valued to-day as a going concern it would be worth more than £45,000. If we had had to buy land and build a factory we could not have done it for the money. Fortunately, we found a place with ample land and with the structure of a factory upon it. The people who had bought it made an enormous loss, and we got it c[illegible] Debtors are put down at £34,859. 1s. 9d. Last year they [illegible]03. Setting those debtors to us—and they are all g[illegible] the debts we owe on the ot[illegible] £14,706, [illegible] the money owed to us [illegible]able the[illegible] investment in Consols a[illegible] and ca[illegible] and in hand £8,051 [illegible] the ba[illegible] the appropriation [illegible] fr[illegible] account. You will [illegible] things we original[illegible]

installations, and all sorts of things, the fruit of the want of knowledge of the two original companies, the Edison and Swan. They had made a lot of bad bargains, and had bought a lot of stuff which had turned out badly—dynamos, etc. They put a lot of installations on the theory that rental of light was a profitable thing. But it was exceedingly ruinous. We held that it was wise to cut our first loss, but these men were such babies that they hesitated to realise the loss at the right moment. We realised the loss, and got rid of all these things upon the best terms we could, and the very last of them. We had a lot of dynamos which were useless to us, but we managed to sell them in Italy. We have got rid of them all. Then comes the dividend for the year ending June 30. Then the interest on the A shares for 1885 is wiped out, and then comes 7 per cent in respect of 1886. We thought that was going far enough, and therefore carried the balance [illegible] to reserve, and if you will kindly approve of the recommendation of the Board—because it is in your hands—you will add that to the reserve already set aside, and you will have £22,000 reserve. That is the bare bones of this account. But there is a thing I should like to call your attention to. Of course we are face to face now with this. There is so much capital—a very large sum of money—patents are running out [illegible] years and a few months; and then—the future! Well! one looks with some anxiety upon a past of the kind we have experienced. Cost of patents, etc., as per last balance-sheet—you see that has come down now to £234,638. 17s. 7d. A considerable amount! But I don't think it is an amount about which we need be alarmed. This is the cost of founding this business and carrying it through to that moment when we shall be in competition with all the world. Well! I suppose you will have the most—it is no vain to say it, it would be silly if we could not say it—the most perfect lamp factory in this, and probably in any other country; and we trust that by that time you will have the best reputation in any country. You will have the great perseverance and exceeding skill of your technical advisers, as well as the zeal of your officials and Directors to establish a going concern on a very large scale. This business cannot be conducted on a very large scale, however, without investing a large sum of money, therefore competitors will have to compete with us who are thoroughly equipped, high in reputation, and thoroughly established. Of course we shall have to take our chance in the future, but it will come to this, that you have had a protected period; and if you are able to make a better lamp, or at all events as good a lamp at a price below that of any small maker, or, indeed, any very considerable maker, you can take your chance with the public. It is the old thing—Huntley and Palmer's biscuits—a good reputation, cheap production, and quantity. If we can double our sales we can afford to take a very modest profit on the output; because in a concern of this sort fixed costs are a very material element. We are not dependent merely upon the lamp patent (as I am reminded by our secretary), but we have patents in respect to very important parts of the lamp, holders, fittings, and so forth, which extend a long time beyond the lamp patents, and from which we hope to derive a very considerable annual income in the shape of royalties. You are not only now paying this arrear of dividend with every prospect of this being continued in the future, but you have in the interim between 1884 and 1891 written down £300,988 to £234,6[illegible], and this has been done out of profits; some of it out of sales of superfluous plant and property, but most of it out of the profits. We kept writing down, and writing down, and writing down, before we paid any dividend at all. We said the losses of the business must be compensated before we did so. And that is why you got no dividend. Not because there was no balance made on trade working. The other item is equally satisfactory. You started in 1884, besides your £301,000, with what may be called a living asset—freehold property, interest, etc., £52,000. You have got in the same items this year a good deal more than £52,000, and therefore you are in this happy position. Your original claim, which would have to be liquidated, has been reduced by £66,000, and to put it very roundly—(without going into detail; we are obliged to keep a good deal to ourselves, because a good many people would like to know how and where we make our profits. They may induct as much as they like but induction is not as good as positive information. Therefore, we have good reason for going in for generalities)—roundly speaking, your position in diminished claim in respect of original outlay, and improvements in your investments may be put down as something like £125,000. I think that fact, coupled with the dividend you are getting now, should be taken as not altogether discouraging. With these remarks, and of course subject to the readiness to go into any further detail and answer any questions, I beg to move that the report and accounts for the year ending June 30, 1891, be received and adopted.

This was seconded by **Mr. F. R. Leyland**.

Mr. Pell asked whether all the lamps were made by the Company and were they marked "Edison and Swan"?

The **Chairman**: Yes, the bulk are made by us. We import a few from Mr. Edison. His are marked "Edison," and ours "Edison-Swan."

Mr. Pell had seen a great number not marked at all.

The **Chairman**: Perhaps it is as well that proprietors should remem[illegible]at every incandescent lamp used anywhere ought to be an [illegible] Swan lamp. If they find one that isn't and will let us k[illegible] will give us a reason for knowing why.

Anot[illegible] wanted to know what number of lamps was represe[illegible]res £143,229?

The C[illegible] is a bit of information I cannot give you. woul[illegible] to our opponents. We have a great

diversity of lamps and many different makes at very varying prices, but it is not to our interest to reveal the price of any particular one.

Mr. Hedges remarked on the difficulty he had in dealing with his Swan United shares. He thought they ought to face this matter. Couldn't they get a quotation on the Stock Exchange for them?

The **Chairman** explained that the difficulty with regard to these shares arose from the Edison having been launched into the undertaking under very different circumstances to the Swan. The Swan Company had foreign patents and they kept them up, and the difficulty was that they held the major portion of the shares in this Company, but could not distribute. The Board had tried to arrange the matter, but so far unsuccessfully; it must be dealt with by negotiation.

In reply to another shareholder the **Chairman** explained that they had retained the absolute right to manufacture and sell lamps, and they did this in preference to licensing other makers. But with regard to holders, the same reasons against licensing did not hold good, and they had licensed some eminent firms to make holders.

Replying to a further question and suggestion the **Chairman** said that they had gone on the theory of making things safe. He remembered a time when matters were not quite so pleasant as they were now. The Board desired to safeguard the proprietors. He then put the resolution adopting the report, which was carried unanimously.

The next resolution, moved by the **Chairman**, was the declaration of the three different dividends (*vide* report), which was seconded by **Mr. F. R. Leyland** and carried unanimously.

Mr. Forbes then vacated the chair, and his re-election was moved by **Mr. Leyland**, in eulogistic terms, seconded by **Viscount Anson**, and carried *nem. dis.*

Mr. Leyland was then unanimously re-elected a director on the proposition of **Mr. Forbes**, seconded by **Mr. E. Villiers**.

The re-election of the auditors, Messrs. Welton, Jones, and Co., concluded the proceedings.

DIRECT UNITED STATES CABLE COMPANY.

The twenty-eighth ordinary general meeting of this Company was held on Friday, 17th inst., at Winchester House, Sir J. Pender presiding.

The **Chairman** stated that the revenue for the half-year ended the 30th ult., after deducting out-payments, had been £37,353, and the working and other expenses, including income tax, but exclusive of the cost of repairs, had been £18,113, leaving a balance of £19,240 as the net profit of the half-year, which was increased by the amount brought forward to £24,750. An interim dividend of 3s. 6d. a share for the quarter ended March 31 had been paid, and they now proposed a final dividend of 3s. 6d. a share for the quarter ended the 30th ult., leaving £3,502 to be carried forward. The revenue had shown a falling off of £2,664 as compared with that of the corresponding period of 1890, owing to slackness of business, to some curtailment of trade in consequence of recent fiscal arrangements of the United States Government, and to the temporary loss of traffic with the West Coast of South America through the war in Chili. The investments, which had been increased from £234,993 to £244,652, were entered in the balance-sheet at cost, which was a figure considerably below their present market value. He wished that their prospects enabled him to say that they might soon return to the dividend of 5 per cent. which used to be paid by that Company; but he reminded them that at that time there were only six Atlantic cables, whereas since then another cable had been laid by the Western Union Company, while two more had been put down by the Commercial Company. Since their last meeting the French Courts had, he believed, decided the suit they were engaged in in the English company's favour. He did not, however, wish them to be too sanguine about the money which they might get as the result of the decision.

The report was adopted, and the dividend declared.

COMPANIES' REPORTS.

CROMPTON AND CO., LIMITED.

Directors: H. H. J. W. Drummond, Esq., Bernard Gibson, Esq., Viscount Emlyn, Carleton F. Tufnell, Esq., and Rookes Evelyn Bell Crompton, Esq., and John Francis Albright, Esq. (managing directors).

Third report of the Directors to be presented at the annual general meeting at the City Terminus Hotel, on Wednesday, the 29th July, at 2.30 p.m.

The Directors beg to submit to the shareholders the third annual statement of accounts and balance-sheet made up to the 31st March last. The business of the Company continues to increase, the order-book is well filled, and negotiations are on foot for several important central station contracts, in addition to those at present in hand. The Directors have given considerable attention to improved arrangements at the Chelmsford works for increasing the output, so as to ensure punctuality in the execution of orders. The fitting up of the London works, referred to in the Chairman's speech at the general meeting last year, has also been completed. These alterations and additions have entailed a rather heavy outlay on capital account. Mr. . F. Albright, one of the managing directors, has been on an extensive tour through Canada, the United States, Australia, India, and the Cape, visiting the different agents of the Company, and making arrangements which, it is hoped, will lead to a considerable extension of the Company's business abroad. The date appointed for the meeting of the shareholders has been delayed, to allow for Mr. Albright's attendance on his return to England. The net profits of the year amount to £13,030. 14s. 7d., and after providing for the debenture interest and other payments set out in the revenue accounts, and deducting the interim dividends already paid on both the preference and ordinary shares, there remains, with the £474. 18s. 10d. brought forward from last year, a balance available for dividend of £6,484. 18s. 10d. The Directors propose, after setting aside a sum of £500 as a provision for doubtful debts and contingencies, to declare a dividend of 3s. 6d. per share, making 7 per cent. per annum upon the preference shares, and 5s. 6d. per share—making, with the interim dividend, a total of 8 per cent. per annum—upon the ordinary shares, carrying the balance forward. Sir Charles Grant has retired from the Board, and the Directors have elected Mr. H. H. J. W. Drummond and Viscount Emlyn to fill this vacancy and that caused by the death of Viscount Torrington, mentioned last year. In accordance with the articles of association, Mr. B. Gibson retires from the Board of Directors by rotation, but offers himself for re-election. The auditors, Messrs. J. H. Duncan and Co., also offer themselves for re-election.

STATEMENT OF LIABILITIES AND ASSETS AT 31ST MARCH, 1891.

Capital and Liabilities.

GLOBE TELEGRAPH AND TRUST COMPANY.

The report of the Directors for the year ending July 18th, 1891, states that the net revenue of the Company, after deduction of expenses, amounts to £201,899, which, with the balance brought

forward, makes a total of £201,818. From this amount there has been distributed the sum of £133,059 in interim dividends, leaving an available balance of £68,758. The Directors recommend the payment of a final dividend for the year of 3s. per share on the preference shares, and of 4s. 6d. per share on the ordinary shares, making, with the former distribution, a total dividend for the year of 6 per cent., less income tax, upon the preference, and 5¼ per cent. net upon the ordinary shares (against 5 per cent. for the preceding year), and carrying forward a balance of £1,877. The Imperial German Government have taken over the German-Norwegian Telegraph Company, and will pay off the capital at par. This Company held virtually the whole of the capital, which is now being paid off. The sum repaid has been £66,956, and the balance will be paid next year. The Directors have reinvested most of this capital in shares of the Western Union Telegraph Company and the American Cable Company. There remains a small balance still to reinvest.

CITY NOTES.

City and South London Railway.—The receipts for last week were £689, against £692 for the week ending 11th inst.

West India and Panama Telegraph Company.—The receipts for the half month ended July 15 were £1,981, against £2,858.

The Spanish National Submarine Telegraph Company announce an interim dividend of 2s. a share, payable on 31st inst.

Anglo-American Telegraph Company.—The Directors have declared an interim dividend for the quarter ending June 30 of 12s. per cent. on the ordinary and £1. 4s. per cent. on the preferred stock, less income tax, payable on the 1st of August to the stockholders registered on the books of the Company on July 14, 1891.

Venezuela Telephone Company.—The Company state that the half-yearly interest on their debentures, due on 31st inst., will be paid on presentation of the coupons, either in Amsterdam or at the Consolidated Bank, London. The gross earnings, including estimated returns for May and June (the end of the financial year), based on the April returns, were £16,258 and the net earnings £6,655. The proportion of working expenses to gross earnings had been abnormally large during this period, owing to the fact that the works during the whole of the year 1890, and up to the present time, have been under reconstruction and rearrangement.

NEW COMPANIES REGISTERED.

Italian Electrical Light and Power Company, Limited.—Registered by A. W. Rixon, 10, Austinfriars, E.C., with a capital of £60,000 in £4 shares. Object: to carry on every description of business connected with the generation, supply, and use of electricity for the purposes of light, power, or otherwise. The first subscribers are:

	Shares.
G. Taddei, 83, Via Arenula, Roma	1
P. Alessandri, 92, Via dei Farnesi, Roma	1
J. Reid, 101, Leadenhall-street, London	1
C. E. Stuart, 4, Aberdeen-terrace, Highbury	1
A. P. Windridge, 344, Stanstead-road, Catford	1
T. Wholey, 7, Storey's-gate, S.W.	1
J. Carr, 35, Paget-road, Stoke Newington	1

There shall not be less than three nor more than eight Directors; the first are to be determined in general meeting. Qualification, 25 shares. Remuneration, £50 each per annum, the same to be divisible as they shall think fit.

PROVISIONAL PATENTS, 1891.

JULY 13.

11886. **Improvements in electric arc lamps.** Alexis Cance and Société Anonyme d'Appareillages and d'Eclairages Electriques (Lampes Electriques Cance), 28, Southampton-buildings, London.

11891. **Improvements in and relating to switch devices for effecting the connections in telephone systems.** William Phillips Thompson, 6, Lord-street, Liverpool. (Johann Dietz, Germany.) (Complete specification.)

NOTES.

The Central London Railway Bill was read a third time before the House of Lords on Monday and passed.

Spandau.—The Thomson-Houston Company have obtained a concession for 50 years for an electric railway at Spandau, near Berlin.

Telephonic Extension.—A supplementary trunk line of the National Telephone Company has been completed this week between Edinburgh and Penicuik.

History of Electricity.—The "Chronological History of Electricity," by P. F. Mottelay, appearing in the *Electrical World* is also being published in *Engineering*.

Eastwood House.—On Monday night Captain Selwyn's new hall, Eastwood House, was opened, and the electric light shone on his house-warming meeting.

Electrical Work in Mines.—Before the South Wales Institute of Engineers last week, Mr. Albion T. Snell read a paper entitled "Notes on Electrical Work in Mines."

Telephones in Holland.—The Chamber of Commerce at Breda, Holland, has expressed its desire that the Dutch Government should buy up the telephone service and work it as a State department.

Rechniewski Dynamos.—We learn that Messrs. E. L. Berry, Harrison, and Co., have been appointed sole agents in England for the Rechniewski dynamo, which earned high praises and a gold medal at the Paris Exhibition.

Hampstead.—A long discussion took place on the question of electric light at the last meeting of the Hampstead Vestry, at which Mr. Preece was specially invited. The discussion and consideration was left over till October.

Sunderland.—At the last meeting of the Sunderland Highways Committee the borough engineer reported that he had received several replies to his enquiries from other towns with regard to the electric light, and the matter was referred to a sub-committee.

Asbestos Goods.—The United Asbestos Company, Limited, has for the seventh time secured the contract for the supply of all kinds of asbestos goods required for use in her Majesty's Navy during the ensuing 12 months, including packing, sheeting, cloth, and millboard.

St. Pancras.—Mr. James T. Baron has been appointed chief engineer and general manager to the St. Pancras Vestry for their central station supply department. Mr. Baron was Mr. Wilson Hartnell's outside general manager, and has had much experience in important work.

Paris Lighting.—At a meeting on the 24th inst. the Paris Municipal Council granted to M. Victor Popp the concession for electric lighting of the Entrepôt de Bercy. The lamp hour of 10 c.p. is fixed at 1·8 centimes or 0·18d. At this price everyone would be able to use the light.

Ventilating.—Messrs. J. D. F. Andrews and Co. have, in conjunction with others, purchased the patents, goodwill, and assets of the D. C. Green Ventilating and Engineering Company, and are now fitting an extensive installation of the D. C. Green system of ventilation on board the s.s. "Ophir."

Trinidad and Tobago Cables.—In the House of Commons, on the 23rd inst., in answer to Admiral Field, Baron H. De Worms said the importance of establishing telegraphic communication with Tobago has not been overlooked, and it is hoped that the revenue of that island may before long be able to bear the cost.

Akester Electric Motor Company.—A meeting of this company was held on Monday at Cannon-street Hotel. The proceedings were private. This company was formed to carry out the patents of Mr. Akester in tramway work, and a car was built some time ago and run experimentally at Messrs. Stephen Smith's works at Millwall.

Phonopore.—Those who wish to investigate the properties of Mr. Langdon-Davies's phonopore will have the opportunity to do so in a pamphlet on the "Phonopore Duplex Telegraph," giving full particulars as to working, with drawings, published (in French and English) at 2s. by the Phonopore Syndicate, Blomfield House, E.C.

Khotinsky Accumulators.—The firm of Betts and Co., of Carcassone, have acquired the French patents of Khotinsky for accumulators. The Khotinsky Company have for eight years made these accumulators with much success. They are similar to the Betts accumulator, and the combination is known as the "Khotinsky-Betts" cell.

Gas v. Electricity.—The North British Association of Gas Managers held their thirtieth annual meeting last week in Edinburgh. The president, Bailie Robertson, in his inaugural address, alluded to the rivalry of electricity, but did not consider it had affected gas interests, nor in any way curtailed the sale of gas. He was inclined to look upon paraffin as a far more serious rival.

Society of Arts.—The Prince of Wales at Marlborough House on Monday presented the gold medal of the Society of Arts to Mr. W. H. Perkin, for his discovery of producing colouring matter from coal tar; and to Sir Frederick Abel, for his researches in the manufacture of iron and steel, and his services to the State with reference to war material, and as chemist to the War Department.

Reigate.—The Reigate Town Council on Tuesday resolved that an application be made to the Board of Trade for a provisional order under the Electric Lighting Acts, and that the Mayor (Mr. S. Brookes) be requested to cause the necessary steps to be taken for the carrying out of this resolution, assisted by the borough engineer, Mr. F. D. Clark, A.M.I.C.E., and the town clerk, Mr. C. J. Grece, LL.D.

Cricket.—The return match between a team got up by the *Electrical Review* and *Electrical Engineer*, and one representing Mr. Ronald Scott's electrical works at Acton, was played in Mr. Scott's grounds on Saturday last. The weather was perfect, and an enjoyable game resulted in a well-deserved win for the Acton team. After the match, the visiting eleven were hospitably entertained by Mr. Scott.

Berlin Gold Medal.—From Berlin it is announced that the large gold medal for science has been conferred upon Prof. Du Bois-Reymond, M.D., F.R.S., member and secretary of the Royal Academy of Sciences in Berlin, and director of the Physiological Institute. The professor is best known for the important services he has rendered to science by his researches in the department of animal electricity.

Literature.—We have received the fourth yearly number of the *Fortschritte der Elektrotechnik*, containing summary of electrical progress of the year, references to important articles in technical papers, and description of the work of Messrs. Siemens and Halske, Schückert and Co., and the Allgemeine Company of Berlin, for the Government

departments. To those who read German it is a most valuable epitome.

Paris Lighting.—*Electricité* last week has a long article by M. Frank Geraldy upon the electric lighting of Paris, specially describing, with illustrations of machinery and mains, the Montmartre central stations. The mains are bare cables in a concrete culvert, kept apart by insulators bolted down with iron bolts. Details of the immense eight-pole dynamos made by the Continental Edison Company are given.

Electrical Haulage.—An important step in colliery enterprise in South Wales was made at Abercainaid, Merthyr Tydfil, last Friday, by Mr. F. A. Hankey, M.P., managing director of the Plymouth Colliery Works, and Mrs. Hankey, by the introduction of electrical haulage at Abercainaid Colliery to supersede horses. The installation was carried out by Mr. J. C. Howell, of Llanelly and London. The trial proved very successful.

Bombay.—In commenting upon the action of the Bombay Municipality in the matter of electric lighting, an technical paper asks: "Why not call for estimates for lighting the restricted area now chosen for a period of, say, five years, so that the firm undertaking the work will have some inducement to make full and adequate provision for the success of the experiment? A further proviso that in the event of the experiment proving satisfactory, the period would be prolonged for a period of two or three years, would stimulate enterprise."

Southampton Electric Cranes.—The Southampton Works Committee reported that Mr. J. G. W. Aldridge, the electric engineer, had submitted specifications and form of tender for electric lighting on the Royal Pier with mains and all accessories, and detailed estimate of £509. It was decided to recommend the Board to advertise for tenders. Specifications for two electric cranes on the quay, with mains and all accessories, were submitted, with detailed estimate at £2,461. The agreement with the electric light company was carried.

Cardiff.—Some of our contemporaries are a little in error when alluding to Mr. Massey's appointment as electrical engineer to the Cardiff Corporation, which has been made to appear as if it was a recent arrangement. The fact is that Mr. Massey has already acted for the Corporation for about a year, and helped them with their provisional order. All that was done the other day was to instruct a small committee to examine and report upon, with Mr. Massey's assistance, the electric lighting installations that have been carried out by other towns.

Newington.—The Special Purposes Committee of the London County Council report that they have determined to provide electric lighting at the new weights and measures office at Newington, and have invited tenders for the work of providing the installation. The tenders have not yet been received, but it will be desirable that no delay should occur in carrying out the work, as the office is in course of erection. They recommend that they be authorised to enter into any necessary contract for the provision of electric lighting at the Newington wei[illegible] and measures office.

Observatory [illegible] **Blanc.**—[illegible] being mooted in Paris f[illegible] of an ob[illegible] ont Blanc. M. Jansse[illegible] last [illegible] this undertaking, [illegible] e Ac[illegible] he announced tha[illegible] obtained the sup[illegible] Bonaparte, Baron [illegible] Academy of Fine [illegible] *will have to be* [illegible]

point where the ice is not over 30ft. thick. It is thought the preliminary work will be undertaken at once.

Lyons.—We have already mentioned the project for the utilisation of 12,000 h.p. of the Rhone at Lyons. The municipal committee appointed to discuss the project has reported favourably. Motors of about a horse-power would be greatly in demand amongst the silk weavers, and the power from the turbines might be well utilised at night for lighting purposes. The concession of the gas company expires in 11 years. Meanwhile, they look to the Compagnie de Jonage to carry out the electrical part of the scheme and organise the distribution of electric power.

Pipe Welding.—An interesting description of the first pipe welding plant in Chicago, with illustration of the machine in action, is given in the *Western Electrician* of July 11. The pipes are required for icemaking machines. The generator is a 30,000-watt machine, which delivers current in the primary of the welder at 300 volts, the maximum current being 150 amperes. The welds are made in about 15 seconds, but the number of welds per day, including time handling, is about 225. An average of 55 h.p. is required to weld the 2in. heavy iron pipe. All coils are tested after welding to 500lb. per square inch.

A New Switch.—The *Elektrotechnisches Echo*, No. 2, describes a new switch (with illustrations), which has for its principles the progressive pushing forward of wedge-shaped contacts of a peculiar design. Some of the wedges are furnished with brass facings and some left blank and thus insulated. The continued turning in one direction puts successively contact on and off, and the switch can be used for switching on one, three, or five lamps, etc., or a couple of these switches can be also used for lighting a circuit from either end of a room. They are shown in single and double pole form, and mark a useful type of switch for special purposes.

Prudhoe Hall.—The opening ceremony recently took place of a new Catholic chapel in the North of England at Prudhoe Hall, the residence of Mrs. Liddell. The interior is very handsome, carried out to the designs of Messrs. Dunn, Hansom, and Dunn, architects, and is capable of seating 200 persons. The hall itself is undergoing extensive alterations and additions, and is being fitted up throughout with all the most modern contrivances for comfort and convenience (such as electric light, with which the chapel is also lighted), in a manner which will make it one of the largest as well as one of the best appointed mansions in the county.

Bi-telephones.—M. Mercradier, having had to use microphones in delicate measurements, has found occasion to require forms which might remain to the ears for hours together without fatigue. He has constructed telephones weighing only 50 grammes (against 400 grammes of the ordinary type), and of 1in. to 1½in. diameter. Two of these are connected by a steel magnetic spring passing under the chin, and are pressed closely to the earhole. The steel spring serves also as electric connection for two of the contacts, thus acting mechanically, magnetically, and electrically at the same time. He gives his arrangement the name of the "bi-telephone."

Bideford.—At the last meeting of the Bideford Local Board the [illegible]stion of lighting the quay with electricity was brought [illegible] Mr. Dymond considered it high time, now the Board [illegible] contemplating the laying out of their quay in an attra[illegible]er, that they should have it lighted in [illegible]e best m[illegible]le. He enquired whether it would be pos[illegible] the whole of it lighted with the [illegible] ligh[illegible]w in general use elsewhere, and as [illegible]ty [illegible] come into use at Bideford the

Board should take it into consideration, and see if they could not arrange with the local firm who had already introduced it in Bideford to light the Bideford New Quay.

Colonial Enterprise.—Mr. J. F. Albright, managing director of Crompton and Co., Limited, has just returned after a very successful tour round the world. He started originally with the Iron and Steel Institute for the United States, and then went to Australia to look after the business of the Crompton Electric Supply Company of Australia. After spending some months in various parts of Australia, he went to Ceylon, and from thence to Calcutta. After this he proceeded to Colombo and Mauritius, *en route* for Durban. Making this his headquarters, he went up country to Pretoria, where his company is about to carry out the lighting of the town. We are glad to learn that the change has done him much good.

Permanent Exhibition.—We notice that for some time back there has been established in Paris, in the Passage Jouffroy, a permanent exhibition of electrical appliances, compressed air electric lighting motors, and similar useful facilities of modern civilisation. We should think it might be very well worth while for a few of the larger firms to institute in London, on a modest scale, an exhibition of this nature, with rooms fitted up in every way with electric lighting, heaters, and cookers, with motors applied, and so forth, advertised well in the daily press. The number of people even now who do not realise the benefits of electricity, and do not understand the very rudiments, is still enormous.

Staple Driver.—An extremely simple and cheap, and at the same time effective, little device has been introduced by Messrs. Woodhouse and Rawson in the shape of a patent staple driver for electric or other wires. This tool holds the staple in position until it has penetrated sufficiently far to dispense with further support, and can be driven home with a hammer. It consists of a rectangular tube of the size to hold the staple, inside being a plunger with a movement of about ½in. The points of the staple project, and are placed over the wire, and a blow is given to the opposite end of the plunger, the tool is removed and the staple driven home. It will be especially convenient to the electrical trade for running wires overhead or in corners where the staple cannot be held with the fingers.

Austrian Telephones. — The concession granted several years ago to the Telephone Company of Austria for opening telephone exchanges in the towns of Gratz, Prague, and Trieste will expire in October this year, and the concession for five other towns, Lemberg, Reichenberg, Pilsen, Czernowitz, and Bielitz, held by the same company, will terminate in February, 1893. The company, which is an English one, has received notice that the concessions will not be renewed, and that the exchanges in all the towns mentioned will be worked by the Imperial Postal Department. It has accordingly demanded compensation to the extent of 1,900,000 florins, or about £160,000 sterling, but the Government object to the amount as exorbitant. The dispute will probably be settled by arbitration, as provided in the terms of the concession.

Andes Railway.—The tunnels of the wonderful railway now in course of construction through the Andes for the purpose of establishing communication between the Argentines and Chili are being bored, it appears, by the aid of the electric current. The highest of the tunnels is about 10,000ft. above sea-level, while the pierced mountain is about 12,000ft. From Juncal, in Chili, to Quebeda Navaro, in the Argentines—a distance of about 14 miles—there are, it is stated, no fewer than eight tunnels, of a total length of nearly 9½ miles. It having been found impracticable to employ steam engines from the great expense of raising machines and fuel to so great an altitude, it was decided to utilise the water power available in the valley for supplying the necessary power; and the great turbines are reported to be doing their work well.

The Paris Metropolitan Railway.—The Paris Municipal Council on Saturday continued the debate on the subject of the proposed metropolitan railway, and heard the evidence of the director of the works, and M. Sauton, the reporter, the latter explaining the views of M. Guyot as regards the rights of the Council in the matter. The Council, without deciding at this stage for any of the schemes before them, declared themselves generally in favour of the construction of a metropolitan railway. A clause in the first article dealing with the course to be followed by the railway was adopted, and a motion introduced by Charles Laurent that the line should in no case follow the boulevards, was also passed by 34 votes against 23. The whole of the first article was then agreed to without amendment, and finally the project was adopted by 60 votes against nine.

Hospital Music by Telephone.—The Rev. Frederick Harford, M.A., minor canon of Westminster, has formed a "Guild of St. Cecilia" for the distribution gratuitously of soft and sweet music for hospital patients. Canon Harford is a great enthusiast upon the well-known soothing effect of dreamy music upon sick persons, variously applied since the time of King Saul, and is organising his guild for the purpose of systematically using music as a healing medicament. His proposal is partly to organise bands of violin performers (with muted violins) and portable "pianino" to perform outside the wards, but he has now extended his idea to include the establishment of a complete system of telephonic distribution from a central hall to the various hospitals. Canon Harford has himself written much suitable music, and already enlisted the sympathy of some influential persons in favour of his scheme.

Gas v. Electric Light in New York.—For 40 years prior to the introduction of electricity for lighting purposes in New York City, the increase in the consumption of gas, says a gas journal, averaged about 10 per cent. per annum, while the population doubled every 17 years. Since the adoption of the electric light, however, the increase has been much more rapid. It almost immediately rose to 12 per cent. per annum, and in 1887 it was equal to about 14 per cent. per annum. This ratio was still further exceeded in 1888-9-90. The output of gas in New York is doubling itself now in a period of 6½ years instead of 10 years. The president of the Standard Gas Company thinks that one reason for this very rapid increase is the fact that the electric light has educated the human eye to require more light, and that people are not satisfied with the quantity they formerly regarded as sufficient.

Contracts.—The following are mentioned as likely contracts for the application of electric light: New hospital at Bradford—J. B. Bailey, architect; Dalton-in-Furness, Co-operative Society premises—J. McIntosh, architect, Barrow; Corn Exchange, Gainsborough—D. Macdonald, borough engineer; Weights and Measures Offices, Leeds—borough engineer, Leeds; Bank at Maryborough (Ireland)—J. O'Callaghan, architect, 16, Nassau-street, Dublin; Workhouse at Newcastle; Academy at Stonehaven for Dunottar Educational Trust; Grammar School, Wakefield, apply headmaster; Court House, Cork—Court House Joint Committee, Cork; Library Buildings, Southampton—(W. Henman, architect), apply librarian, Public Library, Southampton; new Municipal Buildings, Oxford—Mr. Bickerton, town clerk, Oxford; Public Library, Brechin, Scotland—architect, J. M. Fairley, 122, George-street, Edinburgh; Police Station, Glasgow—

J. Lang, clerk, City Chambers, Glasgow; Infirmary, Tadcaster—J. A. Bromet, clerk; Arcade at Torquay—J. Watson, architect; Sleight's Hall, Whitby—Clark and Moscrop, architects, Feethams, Darlington.

Maidstone.—At a meeting of the Maidstone Local Board on Tuesday the sub-committee on electric lighting reported a long conference with the manager of the Electric Installation Company, when they ascertained that if the Local Board obtain a provisional order they will experience great difficulty in getting any electric company to take a transfer thereof; that the cost of the smallest installation would be £3 a light, for 5,000 lights, and that if the company carried out the lighting of Maidstone the Board would have the power to purchase the undertaking at any time at a sum yielding 5 per cent. on the outlay. The committee viewed the company's works at Chelsea, which were no doubt as good as any existing at the present time. Councillor Barker urged the appointment of a committee to discuss the question of working the electric lighting themselves or not. He believed it would pay to do their own work. The clerk said they must decide on this course before October 1, or they would again be too late to obtain a provisional order. It was then resolved to appoint a committee to report further on the matter.

Nomenclature.—The German nation are very retrospectively conservative, and strive to make all their terms thoroughly Teutonic and simple. The telephone has been known as the "Fernsprecher,' or far speaker, and now we notice that the telegraph is being termed, in business circulars of Morse telegraph instruments, the "Farbschreiber." In this case the terms are well known, and little good could result from altering them, but in many cases the homely straightforwardness of the German technical terms is really an aid to learners, and the feeling of desire for directness is not one to be despised. Nothing in electrical matters so bothers and frightens the student and the average engineer than those terms, incomprehensible at sight, such as electro-kinetics, hysteresis, and so forth, and even electromotive force, while electric pressure, resistance, lag, dip, etc., almost carry their own explanation. The simplification of scientific nomenclature, as against what might be termed, in imitative verbosity, its "augmented nebulosity," is a matter that deserves constant and serious attention from those who are in the seats of learning as well as from engineers.

Sevenoaks.—At a meeting of the Sevenoaks Local Board on Monday, 27th July, a letter was received from the secretary of the Electric Trust, Limited, referring to the extension of time for executing works under the Sevenoaks Electric Lighting Provisional Order, obtained by them last year, and stating that they had applied to the Board of Trade for an extension of the order for 12 months on the ground that they were in communication with the clerk and surveyor to the Local Board. The clerk (Mr. H. J. Thompson) said that the latter part of the letter was not strictly correct, as no communication had been received from the trust, who, under their order, were bound to commence the work within 12 months, but had not done so. The surveyor said if the Board acceded to the application of the trust, they wo[illegible] giving them a monopoly which might turn out [illegible] to the district. The Re[illegible]n said the [illegible] too late to urge op[illegible] Board ha[illegible]ar not to o[illegible] th[illegible]s not no[illegible] the ord[illegible] to[illegible] The su[illegible]oard wa[illegible] bo[illegible]lerk [illegible]on of Bo[illegible]tim[illegible] it[illegible] Tr[illegible]

Munich.—The Municipality of Munich has decided to erect a central electric light station, and has commissioned Herr Oscar von Miller to prepare a scheme. The report of Herr von Miller states that the motive power, to the extent of 2,250 h.p., will be available from the falls of the [illegible] Four turbines will drive as many dynamos. The lighting of the streets will be carried out by 307 arc lamps, distributed over a circuit of about five miles. The Town Hall, municipal buildings, post office, museum, docks, and other public buildings will take some 6,000 lamps. Motive power will also be distributed. The following is the estimate of the first cost:

Hydraulic construction	1,200,000	marks
Foundations, etc., for engines...	380,000	"
Turbines and races, and erection	353,000	"
Engines and boilers, and erection	175,000	"
Dynamos and electric apparatus	264,000	"
Mains	1,028,000	"
Total (say, £170,000)...	3,400,000	marks.

The cost of running, including interest on capital and depreciation, are given at 600,000 marks. The lamp-hour of 16 c.p. will bring 1·4 pfennig (·17d.), and the lamp-hour per arc will be 14·1 pfennig (or 1·7d.).

London County Council.—The Highways Committee at last meeting reported that they had considered a notice dated 21st July, 1891, from the Metropolitan Electric Supply Company, of intention to lay mains in Amberley-road and Bloomfield-street, Paddington. The proposed works are similar to those of this company which the Council has approved on previous notices, and they recommend that the sanction of the Council be given to the works referred to in the notice upon condition that the company do give two days' notice to the Council's chief engineer before commencing the works; that the mains be enclosed in iron pipes or efficient casing and be laid under the footways wherever it is found practicable to do so; that, as an additional precaution against accident through defective insulation of the mains each of the street boxes shall be provided with an inner as well as an outer cover, the two insulated from each other as far as practicable; and that the outer cover, which shall consist of an iron frame filled in with material to suit the paving, shall be efficiently connected to earth. They also have to report the receipt of a notice, given in accordance with the decision of the Council to accept four days' (instead of one month's) notice, in respect of the laying of service line from mains already laid from the Electricity Supply Corporation to supply No. 37, Strand.

Iron and Steel.—Engineers of every kind have nowadays to face the problems of the utilisation of iron and steel in nearly every department of their constructive work, and to those who experience does not lie amongst the actual foundry and forging practice, a book such as that we have before us should be invaluable. Its title explains itself—"Economics of Iron and Steel—being an attempt to make clear the best everyday practice in the heavy iron and steel trades to those whose province it is to deal with the material after it is made," by H. J. Skelton (illustrated; Biggs and Co., 5s.). Mr. Skelton traces from the iron ore the manufacture of pig iron, explaining the varieties of ore and of pig, and the qualities of the best kinds and brands of cast and wrought iron. Particular attention is everywhere given to the description of the most usual processes and sections, so that customers [illegible]ering may know what are the most easily obtainable [illegible] The actual methods of best modern practice are [illegible]d at some length, and the work is illustrated not only [illegible]ions and details of pig, angle, tee, and other iron [illegible] with many photographic reproductions of actual

works taken from the Ebbw Vale, the Lilleshall, and the Steel Company of Scotland works. The chapters on steel are equally practical; the methods of manufacture are described and compared, and the applications dealt with. Great attention is paid to the question of testing both iron and steel, and much information not otherwise easily attainable is given, as Mr. Skelton has at command full particulars from a large trade experience of the manufacturers', Admiralty, and Board of Trade tests. The work concludes with a score of pages giving a very complete list of the trade sizes of rolled iron and steel, with comparative prices and remarks, and altogether makes one of the most useful books of reference that an engineer could place in his library.

Egremont. — The last monthly meeting of the Egremont Local Board had before them the question of electric light. It being stated that the gas rate would be 4s. per 1,000 cubic feet, a letter was read from Messrs. Nicholson and Jennings stating that the cost of a complete light installation, excepting motive power and house, would be £1,972. 10s. They also asked for information as to the River Eden with a view to it being utilised as motive power. The chairman said it appeared the outlay in adapting the electric light would be very expensive. The clerk said Messrs. Nicholson and Jennings originally fixed the cost at £3,000, but if water were going to be used as the motive power they had reduced it to £1,972. The surveyor stated the gas came to about £300 a year. The gas costs about £200, besides the cost of other work. The view was expressed that there would not be enough water in the river during the summer months. The chairman referred to the installation at Keswick. Mr. Smith stated there was plenty of fall and power—any amount. The chairman thought they ought to be sure of having it all the year round if the public were to have the benefit of it in private houses. Mr. Armstrong thought the tender a remarkably small one. They could borrow £2,000 at 4 per cent. It might be too late in the year to entertain it now; but if the gas company did not give them better terms another year it should be seriously considered. Mr. Stout said there was not the slightest doubt but that they were paying far too much for the gas. Whitehaven had it at 3s. 2d., and the only difference in producing it at Egremont would be the carriage of coal. The chairman said the gas company had laid out a lot of money in putting down the pipes. He did not think they could let them have gas much cheaper. After further discussion, the surveyor was instructed to report upon the subject at the next meeting, and it was agreed to supply the information asked for by Messrs. Nicholson and Jennings.

British Association.—The president-elect of the Cardiff meeting is Dr. William Huggins, F.R.S., one of the most eminent astronomers living, whose spectroscopic researches on the celestial bodies have yielded the most brilliant results. It is probable, then, that Dr. Huggins's presidential address will deal mainly with the work of his life, and he may be expected to review briefly the results which have been achieved by the application of spectroscopic photography to the heavenly bodies. From the president, Prof. O. J. Lodge, F.R.S., of Section A (Mathematics and Physics), something at least original, if not startling, may be expected. It is understood that he proposes to advocate the establishment of a permanent Government physical laboratory on the lines of the Greenwich Observatory to be devoted to physics instead of astronomy; taking up the more serious quantitative determinations, and the observation of molecular changes in the properties of materials. It is proposed to hold in Section A, if possible, in conjunction with Section G, a discussion on "Units and their Nomenclature," having special regard to the new electrical and magnetic units now becoming necessary for practical purposes. The president of Section G (Mechanical Science) is Mr. T. Forster Brown, the well-known engineer, and his address will deal chiefly with mechanical appliances associated with coal mining, and specially with reference to South Wales. The address will have reference to the application of compressed air to mining purposes, electricity in mining operations, and to modern improvements in shipping coal. The following are among papers which have been promised for this section: Messrs. P. W. Willans and M. Robinson, on the Willans engine; Mr. W. Robinson, on a petroleum engine; Mr. E. Vernon, on the Bénier hot-air motor; Mr. R. H. Thorpe, on the Otis electric elevator; Mr. W. H. Preece, on the London and Paris telephone; Mr. A. R. Bennett, on the telephone of the future; Mr. S. Walker, on colliery lamps; Mr. T. Timmis, on electric lighting of trains; Mr. J. E. H. Gordon, on sub-stations.

Telegraphing Across Indian Rivers.—Of several telegraphic lines running from Calcutta to differents parts of India, there are five proceeding almost due east, three of which convey the Burmese traffic, and the other two the Dacca, Chittagong, and neighbouring traffic The country through which these lines pass is intersected by wide rivers, in which connecting cables are submerged. For instance, the Pudda river, which is seven miles broad near Calcutta, is cabled at two points 12 miles apart; and it often happens that these cables break down while the river is in flood, so that repairs are difficult or dangerous, and a boat service to convey the messages from bank to bank, though practicable, is costly and slow. For some time past, therefore, it has been the practice in such a case to telegraph the message by means of Major Cardew's vibrating sounder through the iron sheathing of the cable instead of the interrupted copper conductor. This innovation is due, says the *Times*, to Mr. W. F. Melhuish, of the Indian telegraph service. Two methods are followed, both of which are quite successful. Either a complete metallic circuit, or "loop," as it is called, is formed by two land lines and two cables, the earth being excluded, or a simple circuit is made of one land line and the broken cable, with the earth as a return wire in the ordinary way. In the latter case, notwithstanding the fact that the iron wire of the cable which form the make-shift conductor are in contact with the water for seven miles across the river, the signals of the Cardew sounder can be read with ease, even when the apparatus is 4in. from the ear. This instrument, which has already been described in our columns, was also tried on the copper conductor of a cable which was completely severed, and the signals managed to pass, either by induction across the break or through the surrounding insulator. It is admirably adapted for telegraph signalling in wild countries or with an army in the field, and, as Indian telegraphists say, "it will work through anything." The method in question has enabled the Indian Telegraph Department to dispose of the local traffic and keep the Burmese lines free for their legitimate business. While upon this subject, we may add that Mr. P. V. Luke, C.I.E., director of telegraphs, Calcutta, is now in England arranging for stores and apparatus to be sent to India, and has contrived a very handy portable field telephone station, consisting of a strong teak box containing a combined receiver and transmitter made in one piece and held by the hand for speaking and listening, together with a call-bell, switch, and two cells of a dry battery. The box is of small dimensions and easily carried in one hand.

THE ORIGINAL ROTARY-CURRENT DYNAMO OF HASELWANDER, AND THE PRIORITY IN THE INVENTION OF THE ROTARY-CURRENT SYSTEM.

From a lecture on the rotary-current system delivered by Dr Epstein, on April 12, 1891, in the Electrotechnical Society of Frankfort, and published in Nos. 32-34, 1891, of

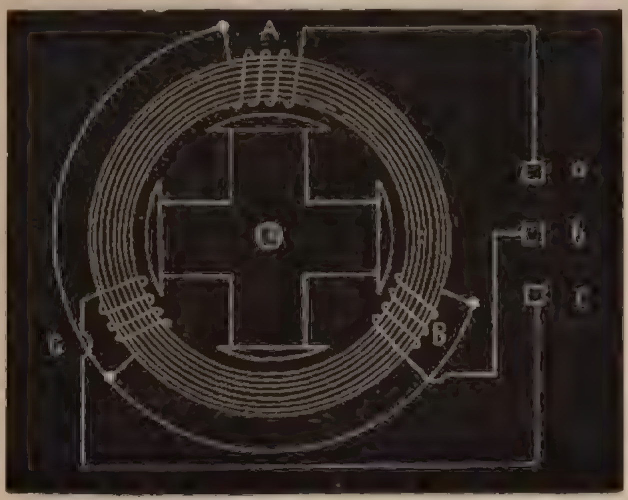

Fig. 1.—Diagram of a Three-Coil Rotary-Current Dynamo.

the *Elektrotechnischer Anzeiger*, we take the following particulars with reference to Haselwander's original rotary-current dynamo, which was exhibited in the lecture hall, and was explained by the lecturer and by the designer, Herr Haselwander.

sets are connected together, the other ends lead to three terminals of the dynamo. To enable the connec- to be understood, the annexed diagram repres the arrangement with only three coils, A, B, a, b, c denote the dynamo terminals. The second dia represents a ring with 12 coils, similar to those of the dynamo. Here the ends of each coil are led to an

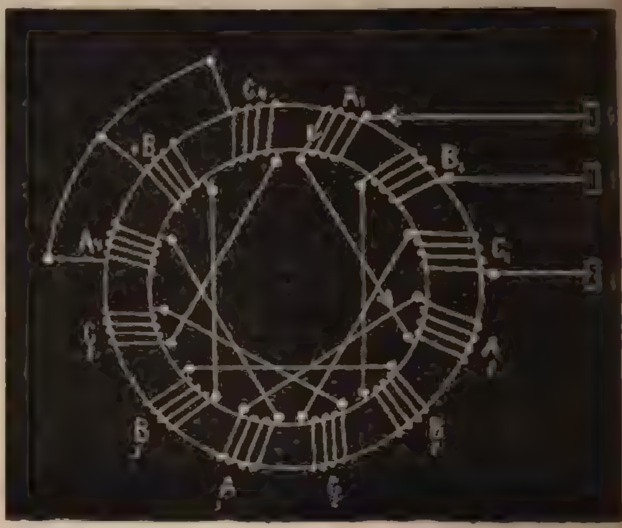

Fig. 2.—Diagram of Connections in Haselwander's Dynam

terminal-board at the front of the armature, and there con- nected to terminal screws. The connections can be made as to generate a strong current at a low pressure, or, versely, a low current at a high pressure. The output of this machine, calculated in continuous current, is

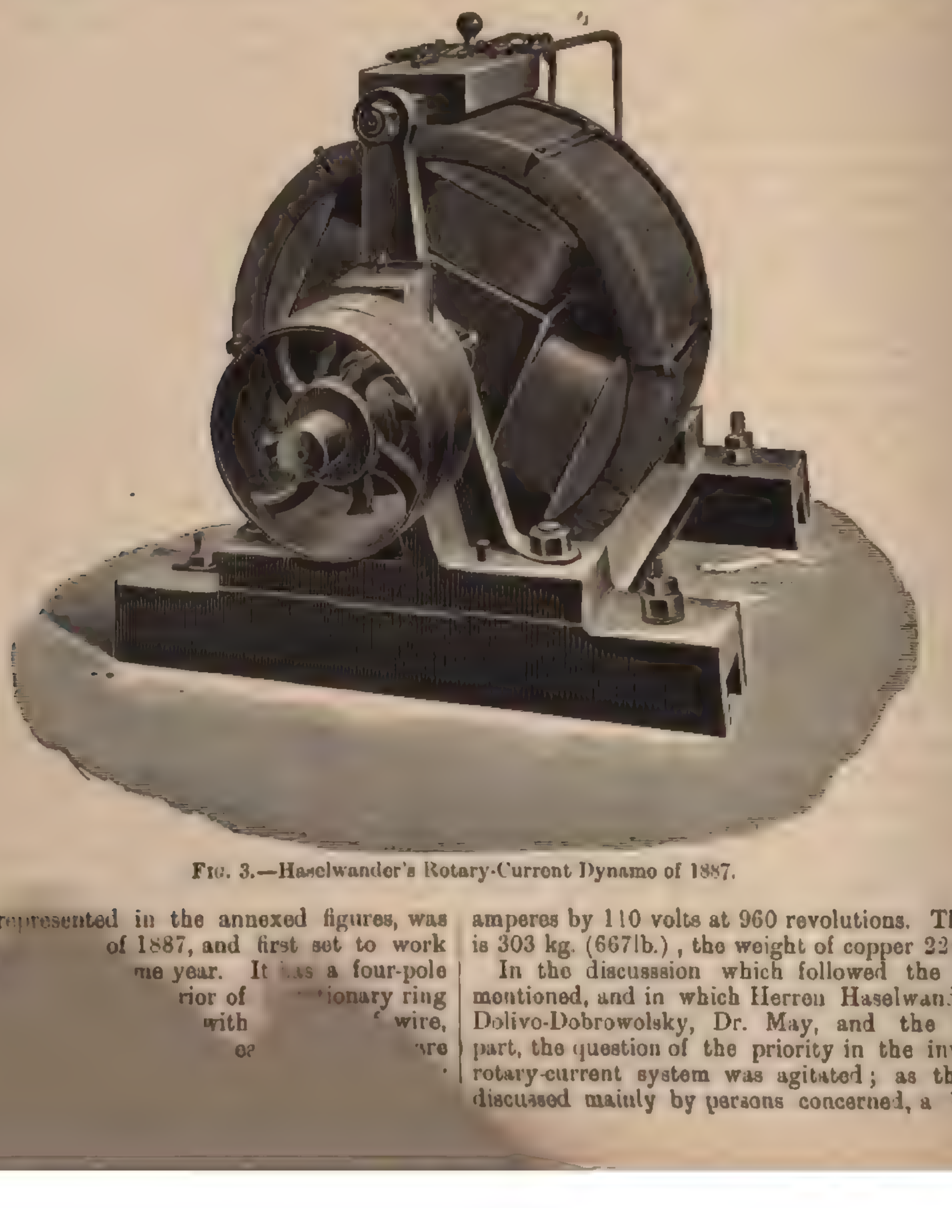

Fig. 3.—Haselwander's Rotary-Current Dynamo of 1887.

This dynamo, represented in the annexed figures, was constructed in the [illegible] of 1887, and first set to work on [illegible] me year. It has a four-pole fie[illegible] rior of [illegible]ionary ring ar[illegible] with [illegible] wire, di[illegible] are grou[illegible] 120[illegible]

amperes by 110 volts at 960 revolutions. The total weight is 303 kg. (667lb.), the weight of copper 22·2 kg. (49lb.).

In the discussion which followed the lecture above mentioned, and in which Herren Haselwander, Lahmeyer, Dolivo-Dobrowolsky, Dr. May, and the lecturer took part, the question of the priority in the invention of the rotary-current system was agitated; as the matter was discussed mainly by persons concerned, a brief historical

account of this invention might be of some interest and not without use for a due appreciation of the relative merits of each inventor.

The first idea of a rotary-field motor belongs to Prof. Galileo Ferraris, who made his experiments relative thereto in the autumn of 1885, and on March 28, 1888, delivered a report upon his system in the *R. Accademia delle Scienze di Torino*; his paper was published in the *Transactions* of that Academy in the same year. By combining two separate equiperiodical alternate currents differing by 90deg. in their phase, he generates in a stationary four-pole field magnet a rotating field which drives a massive or closed-coil armature. He obtains the two working divergent currents from a single alternate current in the following ways: (1) By doubling the original alternate current with its secondary current produced in a transformer; (2) by splitting the original or the secondary alternate current in two branches, one of which is suitably retarded in its phase by means of self-induction; (3) by combining two divergent-phase secondary currents produced by the original in two different transformers, or in a single transformer specially designed for this purpose.

On May 18, 1888, Tesla, in America, reported upon his rotary-field system; the two alternate currents differing by 90deg. he employed for driving a rotary-field motor were generated directly by means of a Gramme armature dynamo and transmitted to the motor by means of four single wires, which number was subsequently reduced to three.

In the summer of 1887 Haselwander, in Germany, designed a four-pole rotary-current dynamo generating a complex current of three currents displaced by 120deg. in their phase, and transmitted by means of three single wires; he employed in his dynamo the so-called open interlinking. On July 21, 1888, Haselwander applied for a German patent, the specification of which, sealed under the same date, on account of some formalities had to be renewed, was accepted in 1880 and published in June, 1890.

On May 9, 1887, Bradley applied for an American patent, the specification of which was published on the 2nd of October, 1888. In this patent he describes the generation of two alternate currents, differing by 90deg. in their phase by means of an ordinary Gramme armature; the currents are taken off four slide rings and transmitted by means of four single wires. In a subsequent patent, applied for on October 5, 1888, and published on August 20, 1889, Bradley reduces the number of slide rings, and that of conducting wires to three, for generating a three-phase current complex, the single currents of which differ by 120deg. in their phase. He employs the so-called closed interlinking.

From this short sketch we see that Ferraris first conceived and worked out into a system the idea of rotary-field working; Tesla first announced the direct generation of two separate divergent-phase currents, by means of a dynamo for driving rotary-field motors; Haselwander and Bradley are the inventors of the generation of the interlinked three-phase rotary current by means of a dynamo for driving rotary-field motors.

The merits of subsequent inventors consist partly in purely practical perfections, and partly in slight arbitrary modifications of the existing system.

THE DISTRIBUTION OF ELECTRICAL ENERGY.*

BY W. C. RECHNIEWSKI.

The object of this paper is to pass in review the different systems of distributing electrical energy, and to examine in what respects each of them is applicable, taking into account the advantages and disadvantages they present.

The two great systems before us are the continuous-current system and the alternate-current system, each of them comprising a large number of subdivisions. Each is capable of giving a good distribution for electric lighting purposes, and the only reason which renders one or other preferable is the cost of installation and of maintenance.

It is solely from this purely practical point of view that we shall study these systems, commencing by the simplest case of all, that of a small and thickly populated district. Everything points to the use of continuous currents for this case.

CONTINUOUS CURRENTS.

1. *Lighting of a Small District.*—We will suppose 3,500 lamps of 10 c.p. uniformly distributed within a radius of 600 yards around a central station, Fig. 1.

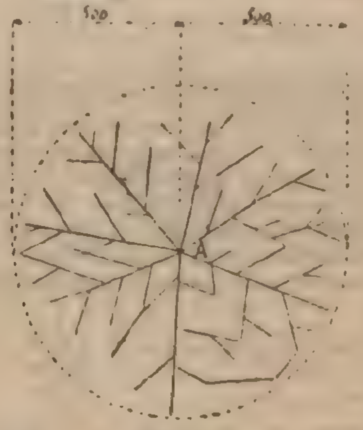

FIG. 1.

We will allow a maximum loss in the mains of 5 per cent. for the lamps that are farthest away, which corresponds to the fall of 5·5 volts in a distributive system of 110 volts. By over-compounding the machines at the central station 2·75 volts, the maximum variation at the lamps will be reduced to 2·75 volts, or 2·5 per cent., which is well within the limits allowed in practice.

Taking the figure of 40 watts per 10-c.p. lamp, the total energy necessary will be 140,000 watts. Two groups of machines of 100 h.p. will therefore suffice, a third being included for safety against accidents.

The following will be the cost of first installation for the central station and mains. (Their equivalents are also given in English money at £40 per 1,000f.)

(*a*) Central station:		f.	£
Sites, buildings, and offices		33,000	(1,320)
Three sets of machines of 100 h.p. (one spare), each including boiler, condensing engine, pipes, belting, etc.	24,000f.		
Dynamos	10,000		
Three sets at	34,000	102,000	(4,080)
Switchboards, instruments, etc.		10,000	(400)
		145,000f.	(£5,800)

(*b*) Mains:

We have allowed a maximum loss in the conductors of 5 per cent.—*i.e.*, 5·5 volts if the normal pressure be 110 volts; this fixes the density of current in the wires for a lamp placed 500 metres (550 yards) away (1,000 metres, or 1,100 yards, return) at 0·4 ampere per square millimetre section (say 260 amperes per square inch).

The total number of amperes is $\frac{3{,}500 \times 40}{110} = 1{,}295$.

The total section of conductor at the entrance to the station will therefore be $\frac{1{,}295}{0 \cdot 4} = 3{,}237 \cdot 5$ mm.^{2} say 32·4 cm.^{2} (or 12 square inches).

The lamps being uniformly distributed around the central station on a radius of 500 metres, the average distance of a lamp from a station will be 333 metres. The total volume of copper will therefore be $2 \times 33{,}300 \times 32 \cdot 4 =$ 2,157,840 cubic centimetres, or 19,280 kilogrammes (42,416lb., or, say, 19 tons), costing at 2½f. per kilo., 48,200f. (£1,928).

It is difficult to estimate the cost of laying mains, as this varies with the distribution of the lamps, the system of mains, whether overhead or underground, the system of insulation employed, etc.; we will take approximately the figure of 20,000f. (£800).

* Translated from *L'Electricien*.

The mains laid up to the doors of consumers will be, therefore, 68,200f. (£2,728).

The expenditure necessary for an electric lighting company to produce the electricity and lead it to the doors of the houses will therefore be :

	f.	£
Central station	145,000	(5,800)
Mains	68,200	(2,728)
	213,200	(8,528)
Working capital, say	36,800	(1,472)
Total capital engaged	250,000f.	£10,000

To estimate the cost of running we should require to know the number of lighting hours per lamp; in other terms, the load diagram of the station. We may in most cases estimate the period of lighting per lamp per day at two hours, which will correspond to about 2 × 40 × 3,500 = 280,000 watt-hours, or 400 h.p. per day.

The expenses of maintenance may be estimated thus :

	f.	f.	£
1 chief engineer	3,600		
1 assistant engineer	2,400		
2 electrical engine drivers	5,200		
2 stokers	4,200		
Staff, total		15,400	(616)
Coal, 3 kg. (6·6lb.) per horse-power hour = 3 kg. × 400 × 365, or 468 tons at 20f. (16s.)	9,360		
Oil, waste, etc.	3,000		
Fuel, etc., total		12,360	(494)
Interest on a capital of 250,000f. at 5 per cent.	12,500		
Depreciation of buildings and mains at 5 per cent. on 101,200f.	5,060		
Depreciation and repairs to plant 10 per cent. on 112,000f.	11,200	28,760	(1,150)
Total expense of maintenance		56,520f.	(£2,260)

These expenses do not include the charges levied by the local authorities, which will vary from one place to another in a manner impossible to estimate generally.

To sum up, with this system of distribution and with an average duration of lighting of two hours a lamp per day, we have as cost of installation per lamp

$$\frac{50,000\text{f.}}{3,500} = 71{\cdot}43\text{f. (£2. 17s. 2d.)}.$$

$$\text{Annual expenditure} \quad \frac{56,520\text{f.}}{3,500} = 16{\cdot}15\text{f. (12s. 11d.)}.$$

The weight of copper in the mains per lamp will be

$$\frac{19,280}{3,500} = 5{\cdot}5 \text{ kilog. (12·1lb.)}.$$

We would point out here that the central station is capable of supplying current for 3,500 lamps burning simultaneously, which presupposes a much larger number of lamps really installed, as it can never happen that all the lamps of a town are burning at the same time.

We will now consider the manner in which the weight of copper in the conductors increases with the dimensions of the district to be lighted, taking the same density of lighting and the same percentage of loss.

Let us suppose that the linear dimensions of the district increase in the ratio of n to 1. The number of lamps will become n^2 times greater ; the density of current in a wire for the same loss will be n times less. The section of mains will thus become n times greater per lamp, that is, in reality n^3 times greater ; their length having also increased in the proportion of n to 1, the weight will therefore be n^4 times greater. That is to say, that the weight per lamp of the mains in a system varies as the square of the linear dimensions of the space [illegible] ted.

Calli [illegible] weight [illegible] lius of the space to be lighte [illegible] we

We have taken r to be 500 metres (550 yards), a[illegible] 5·5 kg. (12·1lb.) ; whence $a = \frac{5{\cdot}5}{250,000} = 0{\cdot}000022$[illegible] therefore,

$w = 0{\cdot}000022\ r^2$ kg. per lamp (or 0·0000484lb. per [illegible]

Thus, for a radius of 1,000 metres, we shall have [illegible]

$$w = 22 \text{ kg. per lamp (48·4lb.)} ;$$

and for a radius of 250 metres

$$w = 1{\cdot}375 \text{ kg. per lamp (3lb.)}.$$

It is therefore seen that the weight of mains pe[illegible] increases very quickly, and beyond 500 metres [illegible] become onerous.

But we can dispose the system of distribution i[illegible] a manner as to diminish this expense, as shown in F[illegible]

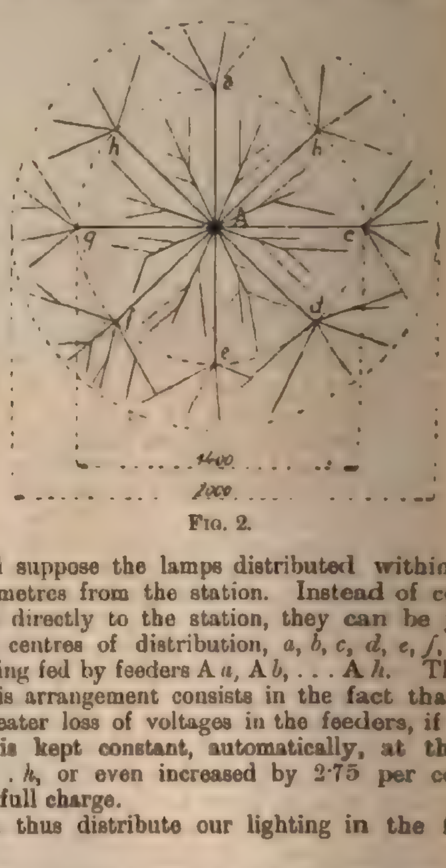

Fig. 2.

We will suppose the lamps distributed within a r[illegible] of 1,000 metres from the station. Instead of conn[illegible] the lamps directly to the station, they can be join[illegible] secondary centres of distribution, a, b, c, d, e, f, g, [illegible] centres being fed by feeders A a, A b, . . . A h. The a[illegible] tage of this arrangement consists in the fact that w[illegible] allow a greater loss of voltages in the feeders, if onl[illegible] potential is kept constant, automatically, at the [illegible] a, b, c, ... h, or even increased by 2·75 per cent[illegible] normal at full charge.

We can thus distribute our lighting in the foll[illegible] manner :

(1) Central district around A of 800 metres diamet[illegible]

(2) Eight districts of 300 metres radius arranged a[illegible] the first. The weight of copper per lamp for the c[illegible] district will be $w = {\cdot}000022 \times 400^2 = 3{\cdot}5$ kg. (7·7lb.[illegible] lamp ; in each of the eight peripheral districts $w = 0{\cdot}00$[illegible] $\times 300^2 = 1{\cdot}98$ kg. (4·35lb) per lamp.

In the feeders we may lose up to 15 per cent.—i.e.,[illegible] volts. Their average length is 700 metres ; this deter[illegible] the density of current to be about 0·6 ampere per s[illegible] millimetre (400 per square inch).

The current per 10-c.p. lamp being about ·36 am[illegible] the weight of feeder per lamp will be 7·5 kg. (16·5lb.[illegible]

To sum up, we shall have in the central district [illegible] lamps, and 2,240 × 1·98 = 4,435 kg. (9,757lb.) of copp[illegible] the conductors. In the exterior districts we shall [illegible] 11,760 lamps ; 11,760 (3·5 × 7·5) = 12,936 kg. (28,4[illegible] The total weight of copper in the conductors per lamp[illegible] therefore be

$$\frac{12,936 + 4,435}{14,000} = 9{\cdot}5 \text{ kg. (20·9lb.) per lamp.}$$

It is thus seen that we economise 22 − 9·5 kg. = 12[illegible] (27·5lb) of copper per lamp by reason of the si[illegible] method of distribution.

But it must not be forgotten that, as we have all[illegible] for a loss of 16·5 volts in the feeders, it will be nec[illegible] to have the plant at the station of greater capacity to[illegible] duce the requisite pressure, and, at the same time, m[illegible] more coal will be used. These disadvantages are cou[illegible] balanced by the diminution of general cost resulting [illegible]

the concentration of a plant of greater power at the central station.

Three-Wire System.—By this system, which is too well known to need description here, five-eighths of the weight is economised at the cost of a slight complication. This system is, moreover, applicable as well for a simple distribution as for a distribution by means of feeders.

Instead of leading back to the station the third wire, which serves solely as compensating conductor, we may employ an equalising system of consumption, consisting of two armatures fixed to the same armature, and turning in the same field.

One brush of each armature is connected with the intermediate conductor, while each of the two other brushes communicate with one of the main conductors. It is easily seen that, when the lamps are not absolutely equally distributed on the two circuits, one of the armatures acts to that extent as a motor, and absorbs the current from the circuit which has too few lamps, while the other armature, acting as generator moved by the motor, produces current, and adds it to the circuit which has too many lamps; this effect therefore tends to equalise the current in the two circuits. Systems of four, five, etc., wires can also be easily employed, the intermediary conductors returning to the station.

The lighting district of the Place Clichy, in Paris, is supplied in this manner with five conductors, and with consumption equalisers, to regulate the current in each circuit.

The dimensions of the compensating conductors may vary from zero to a cross-section, equal to that of the outside principal conductors. Taking all the conductors as equal, we find, taking as unity the expenditure in copper for the simple distributive system, the comparative cost to be:

For the three-wire system and 220 volts at the lamps $= \frac{3}{8}$
  four " " 330 " " $= \frac{2}{9}$
  five " " 440 " " $= \frac{5}{32}$

If we allow 10 kg. (22lb.) as the limit of weight of copper to be employed per lamp, we arrive at a radius of:

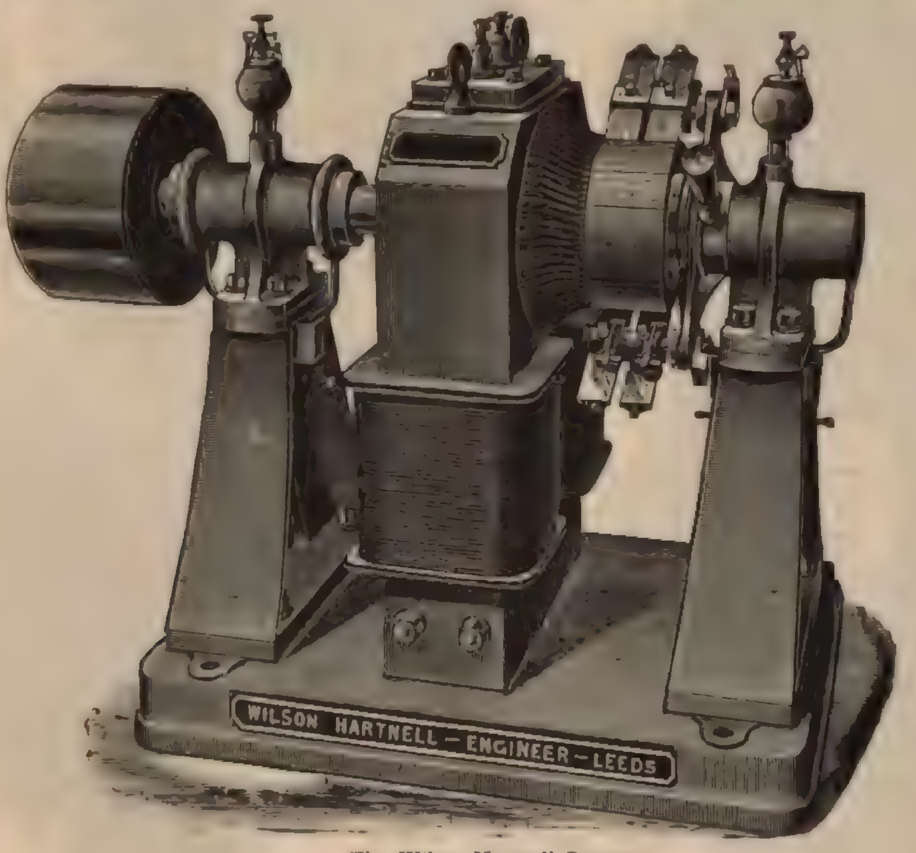
671 metres around the station with the simple parallel system at 110 volts;
1,000 to 1,100 metres with parallel system and ordinary feeders;
1,074 metres with three-wire system;
1,650 to 1,800 metres with three-wire system and feeders;
2,000 to 2,200 metres with five-wire system;
3,300 to 3,600 metres with five-wire system and feeders.

(*To be continued.*)

WILSON HARTNELL DYNAMO.

Mr. Wilson Hartnell, of Volt Works, Leeds, whose name is well known, especially in the North of England, as having carried out some of the largest mill and mansion electric lighting—amongst them Wentworth Castle—has recently taken London offices at 11, Queen Victoria-street, E.C. It may not be yet generally known to our readers that Mr. Hartnell for some little time has been manufacturing his own type of dynamo, and we have recently had the opportunity of inspecting one of the Hartnell dynamos, B type, at the London offices.

The dynamo is well represented in the accompanying illustration. It is a compact, well-finished machine, embodying the latest and best practice in dynamo design,



The Wilson Hartnell Dynamo.

and with some special points of interest. The magnets are of specially annealed wrought iron, and the magnetic circuit is of ample section.

The exteriors are finished bright, and give the machine a very smart look. The principal feature, however, is the armature, which is very large for the size of machine, being 8½in. diameter for the B type, which gives 27 amperes at 110 volts for 1,150 revolutions. The spindle is of steel 1$\frac{3}{16}$in. diameter, and the bearings very long and solid—at the pulley end 6in. long, at the other end 4in. long. They are provided with double oil vessels and oil outlet. The commutator is correspondingly large and solid, being 7in. diameter. This large size makes the machine run very cool and free from sparking, and in practice they show no appreciable wear.

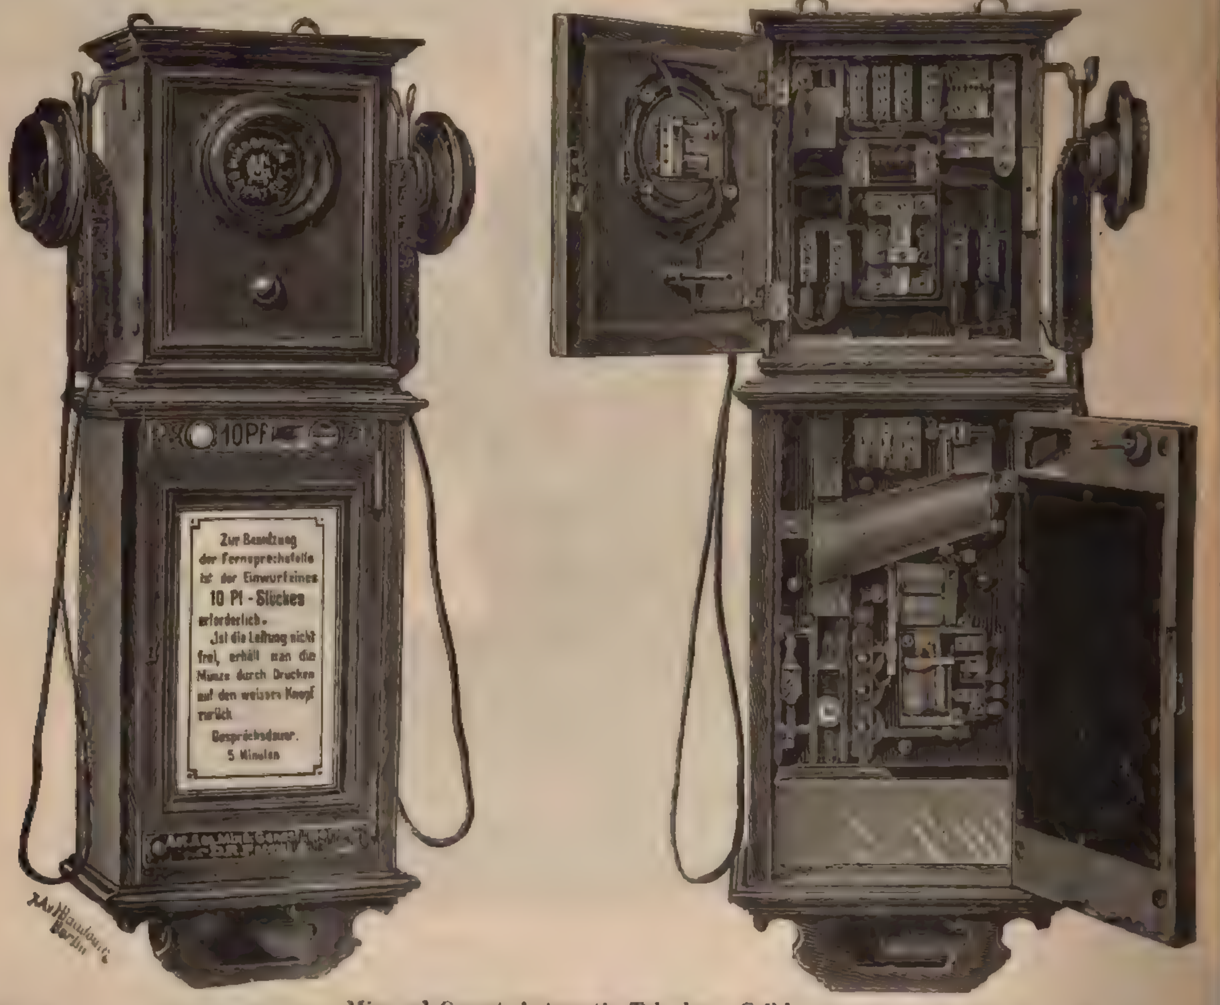
The brushes are arranged on a special carrier, designed by Mr. Hartnell, in which a strong spring is released by a trigger arrangement, and the brushes pressed into position. The same trigger takes off the brushes by an ingenious reverse action.

These dynamos are being manufactured at Volt Works, Leeds, and Mr. Hartnell is ready to supply the trade or colonies. Their qualities for continuous running, by

reason of good design and the capacious armature, seems very high. There are several cases in which the dynamos are running continuously without stop, from Monday morning to Saturday night, amongst these being the Wheldale Colliery, Castleford, as well as mills at Wakefield and other places.

Messrs. Fison and Co., of Leeds, whose works were fitted up by Mr. Hartnell, have recently spontaneously stated that "it is a distinct pleasure to go round the mill and see the excellence of the light, the finish of the workmanship, and the evident proof that everything is good of its kind."

As Irish lighting is now to the fore, it may be mentioned that Mr. Hartnell has recently completed the lighting of a large mill in Cork for Messrs. Furlong and Son, the result of which was so satisfactory that orders were at once received to fit a similar plant for Messrs. Hallinan and Sons, of Fermoy, immediately followed by a second installation for Messrs. Furlong's new mills.



Mix and Genest Automatic Telephone Call-box.

The commercial efficiency of the dynamo is 93 to 94 per cent. in the larger sizes, and it may also be run as a motor, giving an efficiency of about 80 per cent.

THE ABOLITION OF TELEPHONE RENTALS.

The expiry of the Edison patent will, in all probability, mark the commencement of a new era in the development of telephonic communication. With the demand for increased efficiency has also come that for a more equitable system of charging for the use of this convenient and expeditious method of intercourse. At present the same annual rent is required from the subscriber who, perhaps, only uses his instrument once or twice daily as from the stockbroker, whose daily "calls" often amount to hundreds. Again, the provision made for the great body of the non-subscribing public, in the shape of "call-boxes," is, to say *the least*, neither ample nor easily accessible. Such a state of things, in which the public convenience is ... sacrificed to that of the various companies concern... certainly not a common-sense one, and our present ... is to enquire how it may be remedied, with ... satisfaction and profit to both the general public and ... telephone companies.

With regard to subscribers, the system of ch... according to the number of conversations naturally ... itself as being perfectly fair in principle, while it does ... with a good many superfluous calls, and thus light... labour of the exchange attendants. On the other ... however, it may be urged that the increase of ... labour, rendered imperative by the necessity of keeping ... account for each subscriber, more than balances ... advantages. Clearly, then, there is but one way in ... the proposed reform can be effected, and that is by ... introduction and adoption of a system whereby communica... tion can be obtained from any point of a far-spreading ...

like London, payment being made at the time each conv... sation takes place, without the customer being subjected ... the formality and inconvenience attendant upon the use ... the present "call-box."

That the idea of prepayment for each conversation ... feasible, is proved by the great success which has attend... its adoption by the English Government upon the Lond... Paris telephone line. Another argument in its favour ... that if properly carried out in the manner indicated abo... it would completely prevent the frauds to which ... telephone companies are at present subject. It is a we... known fact, that although telephone subscribers are pr... hibited from allowing outsiders to use their instrumen... they are so frequently and persistently pestered by th... non-subscribing friends for "the use of your telephone ... a moment," that they are obliged to give way occasional... and thus the company is defrauded. The adoption of su... a scheme as that propounded above would, it is obvious, p... complete stop to this, supposing the principle of "paym... before conversation" to be taken as a *sine quâ non.*

As far as we are aware, all efforts made to solve the problem ·hich we are now considering have hitherto resulted in ilure; but very recently an apparatus has been patented y the Actien Gesellschaft Mix and Genest Company, of erlin, which they claim, with some show of reason, to lfil all the conditions necessary for its complete and effecual solution. A short description of the construction and orking of the machine, which is described by its inventors s an "automatic call-box," and which is represented in levation at Fig. 1, and opened to show internal arrangeents at Fig. 2, may be interesting.

Upon a coin being inserted into the slot, it first passes brough the usual arrangement for testing with regard to iameter, thickness, and weight. Should it fail to pass the est, it is rejected, but if it proves satisfactory, it passes to pair of grooves, which are movable upon a hinge. Here ts progress is arrested by the upper of three wheel egments, which, protruding into the side of the grooves nd actuated by the armature of an electromagnet, form a heck arrangement. Just before reaching this point, the oin has pressed a small projecting lever, thus making ontact and allowing bell to be rung, when the black knob n front of telephone instrument is pressed. The call is nswered in the ordinary way from the central exchange, nd if the customer is informed that for any reason the required communication cannot be obtained, he has only to press the white stud, when the movable grooves are thrown forward, releasing the coin from the check arrangement, and allowing it to fall to the refunding box.

Should, however, the desired connection be made at the exchange, the current passes through the electromagnet, attracting the armature with a force sufficient to overcome that exerted by its own spring. The coin thereupon falls to the fixed pair of grooves, and is arrested by a segment. Here it remains until the signal at close of conversation is given, when it is again released by the magnet and allowed to fall into the cash-box, pressing *en route* a second lever which, being connected diagonally with it, replaces same, and at the same time breaks contact. This second lever is of such a length that the coin passing to the refunding box presses it, replacing the first lever and breaking contact as if at close of conversation.

Should, however, the closing signal be omitted, it is obvious that the coin will remain in position. In order to prevent loss from this cause a lever, connected at one end to the armature, and terminated at the other by a small roller, projecting into a slot, is provided. By this means the armature is moved, as if electrically, upon insertion of the next coin, and the one remaining in the instrument has fallen into the cash-box before the other has passed through the testing arrangement.

To sum up the advantages claimed for this instrument:

(1) The exchange can only be rung up upon the insertion of a particular coin, connection being thereupon automatically made for the purpose.

(2) The money is refunded if the desired communication is not to be obtained.

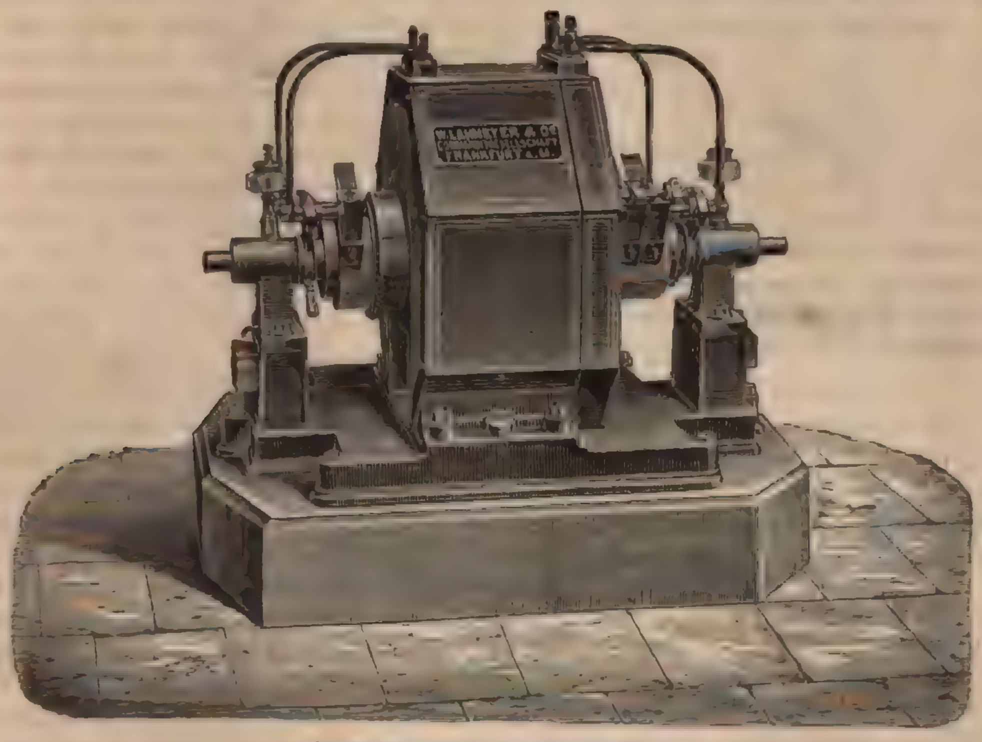
(3) The line is automatically interrupted upon close of conversation.

(4) Absolute security against loss, either on the part of the company or of the customers, no tampering or failure being possible.

The apparatus is now being tested by several European Governments and telephone companies, and after the expiry of the Edison patent it will be shown at the London depôt of Messrs. Mix and Genest, 34, Aldermanbury, E.C., in actual operation.

LAHMEYER DYNAMOS.

We illustrate herewith the continuous-current dynamo of Messrs. Lahmeyer and Co., of Frankfort. The Lahmeyer dynamo is a compact and neat form of machine which has achieved great popularity in Germany. Messrs Lahmeyer and Co. are also the makers of the Haselwander rotary-current dynamo, an article upon which appears elsewhere. Both machines are exhibited in the Frankfort Exhibition.



Lahmeyer Continuous-Current Dynamo.

TELEPHONE COMPANY OF AUSTRIA.

The eighth ordinary meeting of this Company was held yesterday (Thursday) afternoon at the offices, Mr. Henry Grewing, chairman, presiding. The report shows a total to credit of profit and loss account of £4,485. 18s. 9d., after paying debenture interest and interest on preference shares. In view of the expiration of the Company's concessions in October next, and the action of the Austrian Government, the Board do not recommend the payment of a dividend on the ordinary shares at present. With reference to the Company's concessions, the Chairman stated that the particulars forwarded to a daily paper, and given in one of our notes this week, were so accurate they must have been derived from official sources. The Company were ably represented in Vienna by Dr. Eugen Weissel and Mr. Krause. Some of the Directors had already visited Vienna, and others were about to do so again, to try and secure better and more equitable terms from the Government. The Board had hopes of succeeding in this. The report and accounts were unanimously adopted.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence ; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices :

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

*"*THE ELECTRICAL ENGINEER*" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

GOODWILL.

It is an understood thing that balance-sheets are intended to give as little information as possible. There is an item, however, which appears in the balance-sheets of most electrical companies to which exception must be taken. A similar item is also usually to be found in other company work. We refer to the item termed "goodwill." Some time since reference was made to the enormous prices standing against "patents" in some of the balance-sheets, and it was argued that by the time a patent had run out its cost should disappear from the balance-sheet. On the other hand, it was admitted that unless the cost was exorbitant it was not altogether necessary to depreciate annually, so that the cost became *nil* at the expiration of the patent. There seems to be a strong argument in favour of "goodwill" in two cases. Firstly, in this case of patents. These are usually bought during a speculative boom in a particular direction, and, owing principally to promoters' charges, at much more than their real value. Then comes the work of the company in developing a business to sell the goods manufactured under these patents. For a term of 14 years the company has a monopoly, though it often obtains it only at a great cost in litigation to stop infringement. Of course we are only discussing successful patents. Our contention is that though the value of the patents should be depreciated annually, so that at the time of expiration their cost in the books of the company stands at nothing, there should be, on the other hand, an equivalent in the annual increase of the value of goodwill. If the patents are duly depreciated, and no equivalent item entered on the other side, the company, at the end of every year, is in a better position than the figures of the balance-sheet show, because it really has an asset as a going concern, the value of which is not shown. But here comes a difficulty. No amount should be put into a balance-sheet that could not be appraised at the figures given by an independent authority. Now, if goodwill is appraised merely as goodwill at the end of every financial year, it must necessarily be a terribly fluctuating item. The second case where goodwill must be considered is when a business is bought as a going concern. Generally a certain amount based upon past annual profits is allowed for "goodwill." This may or may not figure as a separate item in the balance-sheet. In fact, it is usually lumped in the item purchase money, and as this is expended upon capital account it duly appears upon the balance-sheet. It would be surprising, however to find the item "purchase money" fluctuating in every balance-sheet, as it must do if the value of the "goodwill" is assessed every year.

On the whole, we incline to the opinion that "goodwill" as a separate item is a mistake. In the first case the shareholders can be duly informed that though the patents run out the value of the patents does not run out at the end of fourteen years; and the value should then only be depreciated in the

alance-sheet to the normal—that is, to the value utside of promotion, etc. In the second case the alue is a constant appearing as purchase-money the concern. If this is not done unfriendly critics nay insinuate that the balance-sheet is cooked, and loes not show the real state of affairs. A few housands more or less put to goodwill makes a good or a bad show.

HARD TO PLEASE.

Who is there that has not heard the tale of the man, the boy, and the donkey? First the passers-by laughed at the man for leading the donkey, the boy walking behind. Why was the poor boy to walk with an animal well able to carry him? The boy was put upon the donkey. Then the passers-by reviled at the boy for riding while the old man walked. Then the man got on the donkey with the boy. The passers-by then reviled them for their cruelty in overloading an animal they were more fit to carry than it was to carry them. To please these critics, the man and boy got off, and proceeded to carry the donkey, which in its struggles to get free fell over the parapet of the bridge they were crossing, and so was drowned. Result, no one was pleased. Very much the same sort of criticism goes on now about everything in general, and electric lighting in particular. The state of the law is such that it is best for supply companies to obtain provisional orders. One important question is whether it is better for the company that its shareholders should be local men interested, both as shareholders and users, in local concerns, or outsiders merely investing in what they may deem a good thing. We hold and have always held that where local men hold the shares, the task of introduction is less arduous, and the prospects of ultimate success much greater. Of course where the local authorities procure a provisional order, outside energy is somewhat at a discount. The wisdom of the critics is shown in that when a local authority starts upon the work, it is told the proper course to pursue is to support a provisional order; if the local authority, instead of getting an order, support some enterprising promoter it is still wrong; if, as in the case of Dover, the authority starts for itself, and then repents, and asks for outside tenders, it is still wrong. The Brush Company very naturally, when the Dover authorities stood aside, proposed to form a local company, but this proposal has met with severe criticism. It is said that tenders for electric lighting are like tenders for printing, and that the Town Council would not support an outsider in forming a local company if printing tenders were in question. There seems, in the critic's mind, to be no difference between an expenditure of fifty pounds and one of fifty thousand—in an expenditure for a purely ephemeral purpose, and one that permanently concerns the town. We are told that if a local company had made a proposal, the Town Council were quite ready to entertain it. There was only one objection to this—the local company is not in existence. Surely the next best thing, according to the critic's own contention, is to support the formation of a local company. It seems to us that the aim of the supply and manufacturing companies to assist in the formation of local companies is a good one. They are far different to ordinary promoters. They do not look to promotion-money, or the financial expedients of company-mongers to recoup them for their time and trouble. They imagine that if an active part is taken in the formation and a smaller or larger pecuniary risk, the contract for supplying the necessary apparatus, and for doing the necessary work, will come to them. A local company would have to go to someone for skilled advice, for apparatus, and for material, and why not from the first be under the guidance of a well-known firm? There is no pleasing everybody. Try then in each case to determine the best course, and stick to it.

THE ACCIDENT ON THE ELECTRIC RAILWAY.

It is to be hoped that, in order to ensure greater safety to the travelling public, the directors of the City and South London Railway Company will adopt the recommendation of the jury who met on Monday to deliberate upon the death of Mr. T. Allen Partridge. The deceased, on the 23rd inst., alighted from a down train at about 3.45 p.m., at the Oval Station, and attempted to enter a lift in motion. Unhappily, he was carried up a short distance, when he came into contact with the beam, and his head was completely severed, the body falling into the well beneath. Pending the holding of an inquest the remains were removed to the Lambeth Mortuary.

The evidence given at the inquest, which was held at The Spread Eagle, Lambeth-road, on Monday afternoon, brought to light a certain laxity in the working of the lifts at the Oval Station—at least on the afternoon in question. From the statements made by persons who were in the lift at the time, it appears that the inner expansible lattice door was only partly closed, whilst the outer gate was open. The order being given, "Right away," the lift was started, the porter, Mullings, at the same time endeavouring to close the outer gate. In this attempt, however, he was thwarted. The deceased at that moment came up, and on being told that he was too late for that journey, said, "I can do it," or words to that effect. Thereupon, he pushed the porter aside and tried to enter the lift, but stumbling against the bottom edge of the lift he seized hold of the inner iron gate and was carried upwards, with the result already mentioned. The whole evidence pointed to the incident being purely accidental. One part of Mullings's duties, when a down train arrives, is to go down to the curved passage, to call out "This way to the lift," and to follow the last passenger to it. On the occasion in question, Mullings had, as he thought, allowed the last passenger to precede him, and on his arrival at the lift gave the order for the ascent. It was then, and only then, that the unfortunate Mr. Partridge came up "like a shadow," as the porter explained, the deceased having probably, as is not infrequently the case, remained on the platform to inspect the line.

On the conclusion of the examination of the witnesses, the room was cleared, and the jury deliberated over the evidence. After about 15 minutes' consideration, a verdict of "accidentally decapitated" was given, and the jury recommended that in future the company should give instructions to have both the doors closed before the lifts were set in motion. The solicitor representing the company said the latter sympathised with the relatives of the deceased, and that the remark of the jury should receive attention.

The company would do well to adopt this recommendation. It would also be wise policy to discontinue the

unnecessary hurrying, which occasionally takes place, of passengers from the lifts to the trains, and from the latter to the lifts. The latter is perhaps a matter equal in importance to that of closing both doors.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

TOWNLEY'S ELECTRIC BELL AND DUPLEX ALARM.

SIR,—*Re* Mr. W. B Wynne's patent electric bell, in reply to your correspondents, I wish to state that patent No. 7,373 was not overlooked at the time I applied for a patent for my invention. I failed to see at the time that the principle was the same, and do so at present, except that it was to strike the gong with a hammer, which is common to all electric bells. Certainly I must admit it has been attempted to secure a long contact, but in such a manner that, from an ordinary point of view, is very impracticable. Nevertheless, it is very gratifying to me to learn that they have been supplying these bells for some time, but I must admit that I have never seen or heard of them being in the market, and I have had some few pass through my hands since 1885. As for the fewer working parts and more reliable article, I leave that in the hands of your readers.—Yours, etc., JOSEPH TOWNLEY.

877, Old Kent-road, London, S.E., July 27th, 1891.

SIR,—I should have been rather disappointed had my bell and duplex alarm been allowed to pass by unnoticed by your readers. In reply to your correspondent who merely wishes to show that there is no novelty attached to Townley's alarm, I would venture to say that (after the elaborate description he gives of one that he has had in use since 1886) if he would kindly take the trouble to read carefully the description given in your paper, he will find no mention of any unnecessary fittings; but it is distinctly stated that all complicated parts and switches are entirely obviated, and I may say perhaps, for his personal edification, that such is absolutely necessary to meet the demand of the class for whom this alarm is designed. I may add that this alarm has been in use for the past 12 months without hitch of any kind: this alone is a recommendation.—Yours, etc., JOSEPH TOWNLEY.

877, Old Kent-road, London, S.E., July 27, 1891.

EXPERIMENTS WITH ALTERNATE CURRENTS OF VERY HIGH FREQUENCY AND THEIR APPLICATION TO METHODS OF ARTIFICIAL ILLUMINATION.*

BY NIKOLA TESLA.

(Continued from page 83.)

The importance of these elements in an alternate-current circuit is now well known, and, under ordinary conditions, the general rules are applicable. But in an induction coil exceptional conditions prevail. First, the self-induction is of little importance before the arc is established, when it asserts itself; but perhaps never as prominently as in ordinary alternate-current circuits, because capacity is distributed all along the coil, and by reason of the fact that the coil usually discharges through very great resistances; hence the currents are exceptionally small. Secondly, the capacity goes on increasing continually as the potential rises, in consequence of absorption which takes place to a considerable extent. Owing to this there exists no critical relationship between these quantities, and ordinary rules would not seem to be applicable. As the potential is increased either in consequence of the increased frequency or of the increased current through the primary, the amount of the energy stored becomes greater and greater, and the capacity gains more and more in importance. Up to a certain point the capacity is beneficial, but after that it begins to be an enormous drawback. It follows from this that each coil gives the best result with a given frequency and primary current. A very large coil, when operated with currents of very high frequency, may not give as much as ⅛in. spark. By adding capacity to the terminals the condition may be improved, but what the coil really wants is a lower frequency.

When the flaming discharge occurs, the conditions are evidently such that the greatest current is made to flow through the circuit. These conditions may be attained by varying the frequency within wide limits, but the highest frequency at which the flaming arc can still be produced determines, for a given primary current, the maximum striking distance of the coil. In the flaming discharge the *éclat* effect of the capacity is not perceptible; the rate at which the energy is being stored then just equals the rate at which it can be disposed of through the circuit. This kind of discharge is the severest test for a coil; the break, when it occurs, is of the nature of that in an overcharged Leyden jar. To give a rough approximation I would state that, with an ordinary coil of, say, 10,000 ohms resistance, the most powerful arc would be produced with about 12,000 alternations per second.

When the frequency is increased beyond that rate, the potential, of course, rises, but the striking distance may, nevertheless, diminish, paradoxical as it may seem. As the potential rises the coil attains more and more the properties of a static machine until, finally, one may observe the beautiful phenomenon of the streaming discharge, Fig. 6, which may be produced across the whole length of the coil. At that stage streams begin to issue freely from all points and projections. These streams will also be seen to pass in abundance in the space between the primary and the insulating tube. When the potential is excessively high they will always appear, even if the frequency be low, and even if the primary be surrounded by as much as an inch of wax, hard rubber, glass, or any other insulating substance. This limits greatly the putput of the coil, but I will later show how I have been able to overcome to a considerable extent this disadvantage in the ordinary coil.

Besides the potential, the intensity of the streams depends on the frequency; but if the coil be very large they show themselves, no matter how low the frequencies used. For instance, in a very large coil of a resistance of 67,000 ohms, constructed by me some time ago, they appear with as low as 100 alternations per second and less, the insulation of the secondary being ¾in. of ebonite. When very intense they produce a noise similar to that produced by the charging of a Holtz machine, but much more powerful, and they emit a strong smell of ozone. The lower the frequency, the more apt they are to suddenly injure the coil. With excessively high frequencies they may pass freely without producing any other effect than to heat the insulation slowly and uniformly.

The existence of these streams shows the importance of constructing an expensive coil so as to permit of one's seeing through the tube surrounding the primary, and the latter should be easily exchangeable: or else the space between the primary and secondary should be completely filled up with insulating material so as to exclude all air. The non-observance of this simple rule in the construction of the commercial coils is responsible for the destruction of many an expensive coil.

At the stage when the streaming discharge occurs, or with somewhat higher frequencies, one may, by approaching the terminals considerably and regulating properly the effect of capacity, produce a veritable spray of small silver-white sparks or a bunch of excessively thin silvery threads, Fig. 7, amidst a powerful brush—each spark or thread possibly corresponding to one alternation. This, when produced under proper conditions, is probably the most beautiful discharge, and when an air blast is directed against it, it presents a singular appearance. The spray of sparks, when received through the body, causes some inconvenience, whereas, when the discharge simply streams, nothing at all is likely to be felt if large conducting objects are held in the hands to protect them from receiving small burns.

If the frequency is still more increased, then the coil

* Lecture delivered be[illegible]ican Institute of Electrical *Engi*[illegible]mbia C[illegible], May 20.

refuses to give any spark unless at comparatively small distances, and the fifth typical form of discharge may be observed, Fig. 8. The tendency to stream out and dissipate is then so great that when the brush is produced at one terminal no sparking occurs, even if, as I have repeatedly tried, the hand, or any conducting object, is held within the stream; and, what is more singular, the luminous stream is not at all easily deflected by the approach of a conducting body.

At this stage the streams seemingly pass with the greatest freedom through considerable thicknesses of insulators, and it is particularly interesting to study their behaviour. For this purpose it is convenient to connect to the terminals of the coil two metallic spheres which may be placed at any desired distance, Fig. 9. Spheres are preferable to plates, as the discharge can be better observed. By inserting dielectric bodies between the spheres, beautiful discharge phenomena may be observed. If the spheres be quite close and a spark be playing between them, by interposing a thin plate of ebonite between the spheres the spark instantly ceases, and the discharge spreads into an intensely luminous circle several inches in diameter, provided the spheres are sufficiently large. The passage of the streams heats, and after a while softens the rubber so much that two plates may be made to stick together in this manner. If the spheres are so far apart that no spark occurs, even if they are far beyond the striking distance, by inserting a thick plate of glass, the discharge is instantly induced to pass from the spheres to the glass in the form of luminous streams. It appears almost as though these streams pass through the dielectric. In reality this is not the case, as the streams are due to the molecules of the air which are violently agitated in the space between the oppositely charged surfaces of the spheres. When no dielectric other than air is present, the bombardment goes on, but is too weak to be visible. By inserting a dielectric the inductive effect is much increased, and besides, the projected air molecules find an obstacle, and the bombardment becomes so intense that the streams become luminous. If by any mechanical means we could effect such a violent agitation of the molecules we could produce the same phenomenon. A jet of air escaping through a small hole under enormous pressure and striking against an insulating substance, such as glass, may be luminous in the dark, and it might be possible to produce phosphorescence of the glass or other insulators in this manner.

The greater the specific inductive capacity of the interposed dielectric, the more powerful the effect produced. Owing to this, the streams show themselves with excessively high potentials, even if the glass be as much as 1½in. to 2in. thick. But besides the heating due to bombardment, some heating goes on undoubtedly in the dielectric, being apparently greater in glass than in ebonite. I attribute this to the greater specific inductive capacity of the glass, in consequence of which, with the same potential difference, a greater amount of energy is taken up in it than in rubber. It is like connecting to a battery a copper and a brass wire of the same dimensions. The copper wire, though a more perfect conductor, would heat more by reason of its taking more current. Thus what is otherwise considered a virtue of the glass is here a defect. Glass usually gives way much quicker than ebonite; when it is heated to a certain degree, the discharge suddenly breaks through at one point, assuming then the ordinary form of an arc.

The heating effect produced by molecular bombardment of the dielectric would, of course, diminish as the pressure of the air is increased, and at enormous pressures it would be negligible, unless the frequency would increase correspondingly.

It will be often observed in these experiments that when the spheres are beyond the striking distance, the approach of a glass plate, for instance, may induce the spark to jump between the spheres. This occurs when the capacity of the spheres is somewhat below the critical value which gives the greatest difference of potential at the terminals of the coil. By approaching a dielectric, the specific inductive capacity of the space between the spheres is increased, producing the same effect as if the capacity of the spheres were increased. The potential at the terminals may then rise so high that the air space is cracked. The experiment is best performed with a dense glass or mica.

Another interesting observation is that a plate of insulating material, when the discharge is passing through it, is strongly attracted by either of the spheres—that is, by the nearer one, this being obviously due to the smaller mechanical effect of the bombardment on that side, and perhaps also to the greater electrification.

From the behaviour of the dielectrics in these experiments we may conclude, that the best insulator for these rapidly alternating currents would be the one possessing the smallest specific inductive capacity, and at the same time one capable of withstanding the greatest differences of potential; and thus two diametrically opposite ways of securing the required insulation are indicated—namely, to use either a perfect vacuum or a gas under great pressure; but the former would be preferable. Unfortunately neither of these two ways is easily carried out in practice.

It is especially interesting to note the behaviour of an excessively high vacuum in these experiments. If a test tube provided with external electrodes, and exhausted to the highest possible degree, be connected to the terminals of the coil, Fig. 10, the electrodes of the tube are instantly brought to a high temperature, and the glass at each end of the tube is rendered intensely phosphorescent, but the middle appears comparatively dark, and for a while remains cool.

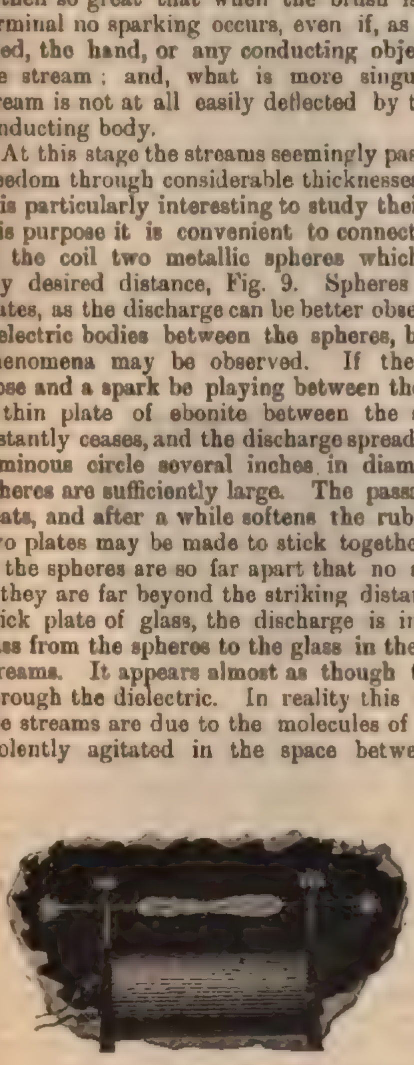


FIG. 6.

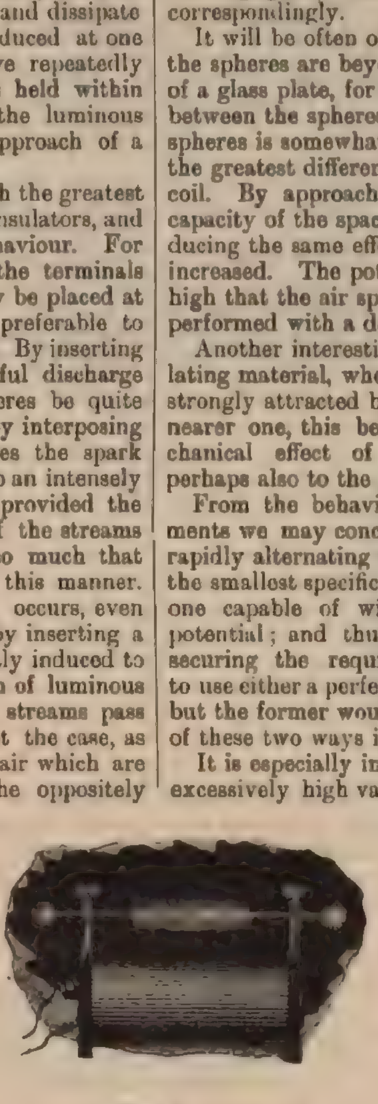

FIG. 7.

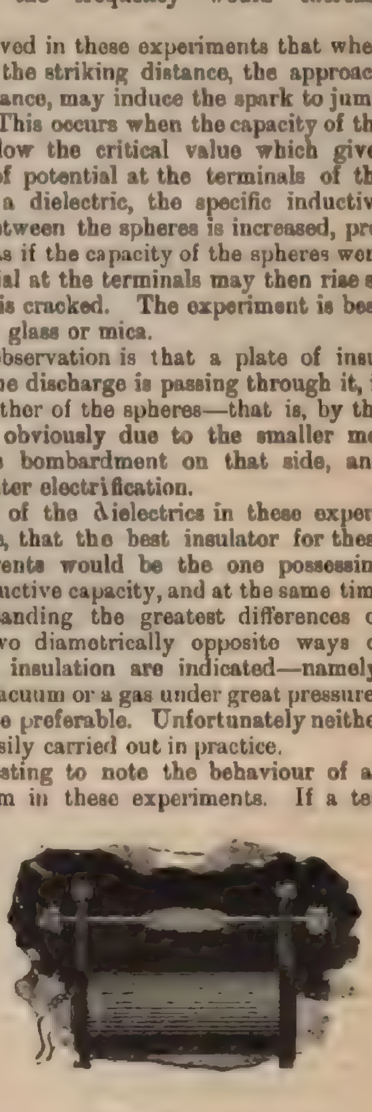

FIG. 8.

When the frequency is so high that the discharge shown in Fig. 8 is observed, considerable dissipation no doubt occurs in the coil. Nevertheless, the coil may be worked for a long time, as the heating is gradual.

In spite of the fact that the difference of potential may be enormous, little is felt when the discharge is passed through the body, provided the hands are armed. This is to some extent due to the higher frequency, but principally to the fact that less energy is available externally, when the difference of potential reaches an enormous value, owing to the circumstance that with the rise of potential, the energy absorbed in the coil increases as the square of the potential. Up to a certain point the energy available externally increases with the rise of potential, then it begins to fall off rapidly. Thus, with the ordinary high-tension induction coil, the curious paradox exists, that while with a given current through the primary the shock might be fatal, with many times that current it might be perfectly harmless, even if the frequency be the same. With high frequencies and excessively high potentials when the terminals are not connected to bodies of some size, practically all the energy supplied to the primary is taken up by the coil. There is no breaking through, no local injury, but all the material, insulating and conducting, is uniformly heated.

To avoid misunderstanding in regard to the physiological

effect of alternating currents of very high frequency, I think it necessary to state that, while it is an undeniable fact that they are incomparably less dangerous than currents of low frequencies, yet it should not be thought that they are altogether harmless. What has just been said refers only to currents from an ordinary high-tension induction coil, which currents are necessarily very small; if received directly from a machine or from a secondary of low resistance, they produce more or less powerful effects, and may cause serious injury, especially when used in conjunction with condensers.

The streaming discharge of a high-tension induction coil differs in many respects from that of a powerful static machine. In colour it has neither the violet of the positive, nor the brightness of the negative, static discharge, but lies somewhere between, being, of course, alternatively positive

FIG. 9.

and negative. But since the streaming is more powerful when the point or terminal is electrified positively than when electrified negatively, it follows that the point of the brush is more like the positive, and the root more like the negative, static discharge. In the dark, when the brush is very powerful, the root may appear almost white. The wind produced by the escaping streams, though it may be very strong—often indeed to such a degree that it may be felt quite a distance from the coil—is, nevertheless, considering the quantity of the discharge smaller than that produced by the positive brush of a static machine, and it effects the flame much less powerfully. From the nature of the phenomenon we can conclude that the higher the frequency, the smaller must, of course, be the wind produced by the streams, and with sufficiently high frequencies no wind at all would be produced at the ordinary atmospheric pressures. With frequencies obtainable by means of a machine, the mechanical effect is sufficiently great to

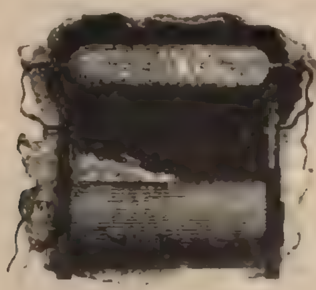

FIG. 10.

revolve, with considerable speed, large pin-wheels, which in the dark present a beautiful appearance owing to the abundance of the streams, Fig. 11.

In general, most of the experiments usually performed with a static machine can be [illegible]rmed with an induction coil when operated with ve[illegible] alternating currents. The effects produced, how[illegible]h more striking, bein[illegible]parably greate[illegible] a small length of c[illegible]covered wi[illegible]tached to one torn[illegible] the stream[illegible]oints of the [illegible] so intense [illegible]sider-abl[illegible] the pot[illegible] ve[illegible]d with g[illegible] [illegible]rminals, [illegible]hin [illegible] [illegible]ns a.

to and fro or spins in a circle, producing a singular [illegible] Fig. 13. Some of these experiments have been de[illegible] by me in the *Electrical World* (New York) of Febru[illegible] 1891.

Another peculiarity of the rapidly alternating dis[illegible] of the induction coil is its radically different behaviour [illegible] respect to points and rounded surfaces.

If a thick wire, provided with a ball at one end and [illegible] a point at the other, be attached to the positive term[illegible] a static machine, practically all the charge will [illegible] through the point, on account of the enormously g[illegible] tension, dependent on the radius of curvature. But i[illegible] a wire is attached to one of the terminals of the ind[illegible] coil, it will be observed that with very high frequ[illegible] streams issue from the ball almost as copiously as fro[illegible] point, Fig. 14.

It is hardly conceivable that we could produce s[illegible]

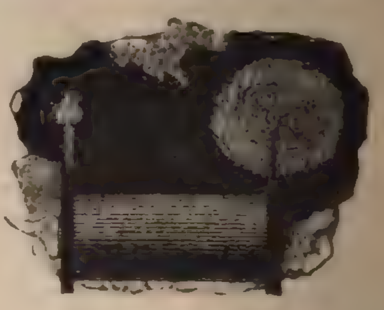

FIG. 11.

condition to an equal degree in a static machine, f[illegible] simple reason, that the tension increases as the squ[illegible] the density, which in turn is proportional to the rad[illegible] curvature; hence, with a steady potential an en[illegible] charge would be required to make streams issue f[illegible] polished ball while it is connected with a point. Bu[illegible] an induction coil, the discharge of which alternate[illegible] great rapidity, it is different. Here we have to deal [illegible] two distinct tendencies. First, there is the tende[illegible] escape which exists in a condition of rest, and [illegible] depends on the radius of curvature; second, there i[illegible] tendency to dissipate into the surrounding air by cond[illegible] action, which depends on the surface. When one of [illegible] tendencies is a maximum, the other is at a minimum[illegible] the point the luminous stream is principally due to t[illegible] molecules coming bodily in contact with the point [illegible]

FIG. 12.

are attracted and repelled, charged and discharged, their atomic charges being thus disturbed, vibrate and [illegible] light waves. At the ball, on the contrary, there is no [illegible] that the effect is to a great extent produced inductively[illegible] air molecules not necessarily coming in contact wi[illegible] ball, though they undoubtedly do so. To convince our[illegible] of this we only need to exalt the condenser actio[illegible] instance, by enveloping the ball, at some distance, [illegible] better conductor than the surrounding medium, the [illegible]ductor being, of course, insulated; or else by surrou[illegible] it with a better dielectric and approaching an insu[illegible] conductor; in both cases the streams will break forth [illegible] [illegible]opiously. Also, the larger the ball with a given frequ[illegible] the higher the frequency, the more will the ball [illegible] advantage over the point. But, since a certain inte[illegible]tion is required to render the streams visible,

obvious that in the experiment described the ball should not be taken too large.

In consequence of this twofold tendency it is possible to produce by means of points effects identical to those produced by capacity. Thus, for instance, by attaching to one terminal of the coil a small length of soiled wire, presenting many points and offering great facility to escape, the potential of the coil may be raised to the same value as by attaching to the terminal a polished ball of a surface many times greater than that of the wire.

An interesting experiment, showing the effect of the points, may be performed in the following manner: Attach to one of the terminals of the coil a cotton-covered wire about 2ft. in length, and adjust the conditions so that streams issue from the wire. In this experiment the primary coil should be preferably placed so that it extends only about half way into the secondary coil. Now touch the free terminal of the secondary with a conducting object held in the hand, or else connect it to an insulated body of some size. In this manner the potential on the wire may be enormously raised. The effect of this will be to either increase, or to diminish, the streams. If they increase, the wire is too short; if they diminish, it is too long. By adjusting the length of the wire, a point is found where the touching of the other terminal does not at all affect the streams. In this case the rise of potential is exactly counteracted by the drop through the coil. It will be observed that small lengths of wire produce considerable difference in the magnitude and luminosity of the streams. The primary coil is placed sidewise for two reasons: first, to increase the potential at the wire, and, second, to increase the drop through the coil. The sensitiveness is thus augmented.

There is still another and far more striking peculiarity of the brush discharge produced by very rapidly alternating currents. To observe this it is best to replace the usual terminals of the coil by two metal columns insulated with a good thickness of ebonite. It is also well to close all fissures and cracks with wax so that the brushes cannot form anywhere except at the tops of the columns. If the conditions are carefully adjusted—which, of course, must be left to the skill of the experimenter—so that the potential rises to an enormous value, one may produce two powerful brushes several inches long, nearly white at their roots, which in the dark bear a striking resemblance to two flames of a gas escaping under pressure, Fig. 15. But they do not only resemble, they are veritable flames, for they are hot. Certainly they are not as hot as a gas burner, but they would be so if the frequency and the potential would be sufficiently high. Produced with, say, 20,000 alternations per second, the heat is easily perceptible, even if the potential is not excessively high. The heat developed is, of course, due to the impact of the air molecules against the terminals and against each other. As at the ordinary pressures the mean free path is excessively small, it is possible that in spite of the enormous initial speed imparted to each molecule upon coming in contact with the terminal, its progress, by collision with other molecules, is retarded to such an extent that it does not get away far from the terminal, but may strike the same many times in succession. The higher the frequency, the less the molecule is able to get away, and this the more so, as for a given effect the potential required is smaller; and a frequency is conceivable, perhaps even obtainable, at which practically the same molecules would strike the terminal. Under such conditions the exchange of the molecules would be very slow, and the heat produced at, and very near, the terminal would be excessive. But if the frequency would go on increasing constantly, the heat produced would begin to diminish for obvious reasons. In the positive brush of a static machine the exchange of the molecules is very rapid, the stream is constantly of one direction, and there are fewer collisions, hence the heating effect must be very small. Anything that impairs the facility of exchange tends to increase the local heat produced. Thus, if a bulb be held over the terminal of the coil so as to enclose the brush, the air contained in the bulb is very quickly brought to a high temperature. If a glass tube be held over the brush so as to allow the draught to carry the brush upwards, scorching hot air escapes at the top of the tube. Anything held within the brush is of course rapidly heated, and the possibility of using such heating effects suggests itself.

When contemplating this singular phenomenon of the hot brush, we cannot help being convinced that a similar process must take place in the ordinary flame, and it seems strange that after all these centuries past of familiarity with the flame, now, in this era of electric lighting and heating, we are finally led to recognise that since time immemorial we have, after all, always had "electric light and heat" at our disposal. It is also of no little interest to contemplate that we have a possible way of producing—by other than chemical means—a veritable flame, which would give light and heat without any material being consumed, without any chemical process taking place, and to accomplish this, we only need to perfect methods of producing enormous frequencies and potentials. I have no doubt that if the potential could be made to alternate with sufficient rapidity and power, the brush formed at the end of a wire would lose its electrical characteristics and would become flame-like. The flame must be due to electrostatic molecular action.

This phenomena now explains in a manner which can hardly be doubted the frequent accidents occurring in storms. It is well known that objects are often set on fire without the lightning striking them. We shall presently see how this can happen. On a nail in a roof, for instance, or on a projection of any kind, more or less conducting, or rendered so by dampness, a powerful brush may appear. If the lightning strikes somewhere in the neighbourhood, the enormous potential may be made to alternate or fluctuate perhaps many million times a second. The air molecules are violently attracted and repelled, and by their impact produce such a powerful heating effect that a fire is started. It is conceivable that a ship at sea may, in this manner, catch fire at many points at once. When we consider that even with the comparatively low frequencies obtained from a dynamo machine, and with potentials of no more than 100,000 or 200,000 volts, the heating effects are considerable, we may imagine how much more powerful they must be with frequencies and potentials many times greater, and the above explanation seems, to say the least, very probable. Similar explanations may have been suggested, but I am not aware that, up to present, the heating effects of a brush produced by a rapidly alternating potential have been experimentally demonstrated, at least not to such a remarkable degree.

(To be continued.)

FIG. 13.

FIG. 14.

FIG. 15.

CAMBRIDGE.

The following letter has been sent by Dr. Porter to the Local Government Board. It will be seen that it deals with the proposal for electrically lighting the town, and is really an epitomised history of the recent action of the Authority :

Peterhouse Lodge, Cambridge,
July 6, 1891.

Sir,—As a member of the Council of the borough of Cambridge, I beg leave most respectfully to draw your attention to the following statements respecting electric lighting in Cambridge :

1. When Colonel Hasted, representing the Local Government Board, held an enquiry at Cambridge, on March 3, 1891, respecting the application of the Council for leave to borrow £35,000 for the purpose of electric lighting in Cambridge, Dr. Fleming, an electrical engineer of high position and great experience, was the professional adviser of the Council, and the system of electric lighting and of engine plant and machinery which the Electric Lighting Committee of the Council submitted to Colonel Hasted as that which they proposed to recommend for adoption by the Council was prepared by Dr. Fleming. Dr. Fleming also gave evidence at the enquiry in support of his scheme.

2. On March 9, 1891, the Electric Lighting Committee generally approved the draft contracts with all the firms suggested by Dr. Fleming, and agreed to recommend their acceptance by the Council subject to the consent of the Local Government Board to their application to borrow £35,000. These contracts included the whole cost of the electric installation except that of the station buildings, plans for which Mr. Fawcett, an architect in Cambridge, was instructed to prepare. With reference to the cost of these buildings, the committee state (report, June 3, p. 7) as follows : "On the 17th March the tenders for the erection of the station were opened, when the lowest tender was found to be several thousand pounds above Dr. Fleming's estimate. Under these circumstance the committee felt they were unable to accept any tender, and that it was their duty to reconsider the matter afresh, as it was clear that this large increase in the cost of the building would, even if the other estimates of Dr. Fleming were accurate, entirely do away with the very small margin of profit which he showed in his report, neglecting as he did the cost of the land and the annual instalments for repayment of capital and for interest."

It may be remarked that the statement of the committee that the lowest tender was found to be several thousand pounds above Dr. Fleming's estimate does not seem to be accurate. It appears from Dr. Fleming's report on tenders, section 11, that the estimate for the buildings was made by Mr. Fawcett, not by Dr. Fleming.

3. In pursuance of this resolution a sub-committee of the Electric Lighting Committee visited the works of the Newcastle and District Electric Lighting Company and of the Corporation of Bradford and drew up a report dated 6th April, 1891, which contains a description of the Parsons turbine employed as the motor at Newcastle and of the electric installation at Bradford, where the Willans engine is used. It appears also from the report that at Newcastle upon a capital expenditure of £17,300 a gross profit of £844 for the half-year ended December 31, 1890, was earned by the sale of the electric current at 6d. per B.T.U., no deduction being made for interest on or repayment of capital, or for depreciation of machinery and plant.

If this capital has been borrowed at the rate of 4 per cent. per annum repayable by annuities extending over 30 years, the amount of each half-year's annuity would be about £450, and if 4 per cent. per annum be allowed for depreciation, the amount to be deducted for the half-year under this head would be £346. The net profit for the half-year would thus be reduced to £48 only. With reference to the expenditure on coal, the sub-committee state (report, April 6, 1891, pp. 3-4) as follows : "It seems that the coal consumed for each unit sold was about 23·4lb. and cost 1·133d. This large consumption is due to the fact that the turbines in use at the Newcastle station are of the old type and require a larger expenditure of steam per horse-power than other engines ; and this tells in an especial degree during the hours when the load on the machines is light. In the improved form which the sub-committee saw at Mr. Parsons's works at Heaton the turbines are steam-jacketed, and the admission of steam is made intermittent at less than full load. Those two changes are said to effect a large saving of steam. And where, in addition, the machines are worked with a condenser there will be a saving, according to the estimate of Mr. Parsons, of 35 per cent. at least. If this should prove to be the case, as the sub-committee believe to be likely, the consumption of steam per horse-power in a turbine will be about the same as in a Willans engine of the same power at full load, and probably much less at light load."

It is no disparagement to the committee to say that in this matter they are laymen and not scientific experts, and that no opinion respecting the efficiency and economy of the Parsons turbine can be of any value unless founded upon the direct experiments of a highly-trained mechanical engineer upon the turbine in its improved form. So far as I know, no such experiment has yet been made, although the electric installation at New Scotland Yard, which contains all the improvements in Mr. Parsons's turbines referred to by the sub-committee, has been in use for several months.

The report concludes as follows : "The members of the sub-committee, so far as they are able to judge, are of opinion that the system tendered for by Mr. Parsons should be adopted, subject to there being no fundamental objection on the part of any expert who may be consulted by the Corporation."

This report of the sub-committee was adopted by the committee on April 7, and in accordance with a resolution of the Council was printed and circulated among the members of the Council under date of 20th April. The report is afterwards referred to under this date.

4. The committee submitted this report to Dr. Fleming for his criticisms, and in reply received his report dated April 14, 1891 (report, June 3, 1891, pp. 7-11). In this report, Dr. Fleming states at length the reasons why he is unable to recommend the system of Parsons, and advises the committee not to decide the question at present without further expert advice.

On the same day on which Dr. Fleming's report was communicated to the committee, a letter, dated April 14, 1891, from Prof. Garnett to Mr. Alderman Finch was also read to the committee (report, June 3, 1891, pp. 11-13). In this letter Prof. Garnett advocates the system of electric lighting which had been carried out by Mr. Parsons at Newcastle-upon-Tyne as well adapted for the requirements of Cambridge.

In consequence of the expression of views adverse to the adoption of the Parsons's system, Dr. Fleming received from the town clerk the following letter, dated April 20, 1891: "I have been requested by the Electric Lighting Committee to acknowledge the receipt of your report on Mr. Parsons's scheme. In the event of their determining to proceed with the lighting of Cambridge upon the system in force at Newcastle, it would be useless after the opinion expressed in the latter part of your report to expect you to assist the Council in carrying out the work, and the committee are therefore of an opinion that any engagement with you as electrical adviser or expert should cease, and have directed me to communicate their views to and to ask you to send in a statement of your charges with a view to payment."

It is not within the object of this letter to discuss the legality of the action of the committee. I content myself with observing that it was not within the competence of the committee to dismiss an officer whose appointment was communicated to him by the town clerk under date June 24, 1890, in the following terms : "I have to inform you that the terms stated in your letter describing the scope of your duties in regard to electric lighting in this town were approved by the Electric Lighting Committee and on their recommendation have been sanctioned by the Council subject to a slight alteration in paragraph 'B,' which should run thus——."

5. At the meeting of the Council held on May 14, 1891, the Electric Lighting Committee recommended, under date

st May, 1891: "I. That the report of the Electric Lighting Sub-Committee dated the 20th April, 1891, and which has already been printed and circulated, be adopted by the Council. II. That in the event of the above report being carried, Prof. Wm. Garnett, of the Durham College of Science, of Newcastle-on-Tyne, be appointed to act as consulting engineer in carrying out the scheme for lighting the borough with electricity submitted by Mr. Parsons." Notwithstanding the concluding statement in the report of the sub-committee quoted in section 3 of this letter, the report of Dr. Fleming, the professional adviser of the Council, which had been in the hands of the committee for nearly a month was withheld from the Council. As I had previously become aware of the existence of this report, and considered it unfair both to Dr. Fleming and the Council that this document should be withheld from the consideration of the Council, I moved the following resolution, which was adopted by the Council: "That the consideration of the report of the Electric Lighting Committee, dated the 20th April, 1891, be postponed until the report of Dr. Fleming, dated the 14th April, on the above report of the committee, the report of any expert who may have been consulted by the committee in accordance with the resolution of the Council passed at their last meeting, together with all documents or correspondence of a public character bearing on the question, have been communicated to and considered by the Corporation."

6. In accordance with the preceding resolution, the Electric Lighting Committee issued their report, dated June 3, 1891, which was circulated to members of the Council on the evening of June 9.

The question of the adoption of the report of the Electric Lighting Committee of May 1, 1891, and of an additional recommendation of the committee dated June 9, 1891 – namely, "That in the event of their report of 1st May being adopted by the Council, they be authorised to conclude contracts for the carrying out of the electric lighting of the town on the general lines of that report, it being understood that the total cost shall not exceed £26,500, and that the installation shall suffice for 5,000 lights of 16 c.p. or their equivalent"—came before the Council on June 11, 1891, but it was generally felt that sufficient time had not been allowed for the consideration of the report, and the discussion was adjourned till June 16.

7. It must, I think, be regarded as an unsatisfactory arrangement that the committee who dismissed Dr. Fleming, because he expressed an opinion adverse to the employment of the Parsons turbine as the electric motor in Cambridge, should without the sanction of the Council have appointed another expert known to them, from his letter of April 14 to Mr. Alderman Finch, to be in favour of Mr. Parsons's system. For this reason, I cannot regard Prof. Garnett as a neutral expert qualified to decide the point at issue between Dr. Fleming and the committee. Careful consideration of Prof. Garnett's letter and subsequent reports, as given in the report of the committee of June 3, justifies me in stating that his conclusions, like those of the sub-committee, rest on hypothesis and not on the solid basis of direct experiment on the improved form of turbine.

8. It may be assumed that a corporation would not be justified in undertaking a commercial enterprise such as electric lighting, which could necessarily be beneficial to a limited portion of the community only, without a reasonable prospect of earning a profit in relief of the rates. The value as regards economy in working of the improvements in the Parsons motor is at present only matter of conjecture. Further, when regard is had, on the one hand, to the increased price of 8d. per B.T.U. authorised to be charged in Cambridge as compared with 6d. charged in Newcastle, and, on the other, to the increased price of coals in Cambridge as compared with the price in Newcastle, it is doubtful whether any profit whatever would be earned by the use of the Parsons system, when deductions were made for interest on and payment of capital and for depreciation of machinery and plant.

9. For these reasons, when it was proposed to adopt the recommendations of the Electric Lighting Committee at the adjourned meeting of the Council held on the 16th of June, I moved the following amendment:

"That after careful consideration of the reports of the Electric Lighting Committee of Mr. Parsons and Prof. Garnett in favour of the adoption of the Parsons turbine as a motor for electric lighting in Cambridge, and the report of Dr. Fleming, the professional adviser of the Borough Council, against its adoption, the Council are unable without further professional advice upon the point at issue to adopt the report of the committee.

"That no further expenditure be incurred by the Electric Lighting Committee until a reply has been received to the application of the Council to the Local Government Board to grant leave to borrow £35,000 for the purpose of electric lighting in Cambridge.

"That in the event of the Local Government Board granting the application of the Council, and of the Council determining to proceed with the system of electric lighting, the question at issue between the Electric Lighting Committee and Dr. Fleming as to the efficiency of the Parsons turbine as a motor be referred to Mr. A. B. W. Kennedy, consulting engineer, formerly professor of engineering in University College, London, to report thereon to the Council.

"And that the town clerk be instructed to inform Dr. Fleming that the letter dated April 20, 1891, which the Electric Lighting Committee instructed him to write to Dr. Fleming conveying their resolution to terminate his engagement, was not submitted to, and has not received the sanction of the Council."

The amendment was rejected by the Council, 19 voting against it and 11 in its favour. The recommendations of the committee were then adopted by the Council.

10. In conclusion, I venture to ask that under the changed circumstances of the case since the enquiry was held in March last, the Local Government Board would order a further enquiry into the efficiency and economy of the Parsons system which has now received the sanction of the Council, before giving their consent to the application of the Council to borrow £35,000 for the purpose of electric lighting in Cambridge.—I have the honour to be, Sir, your most obedient servant, JAMES PORTER.

To the Secretary of the Local Government Board.

THE ELECTRIC TRANSMISSION OF POWER.*

BY GISBERT KAPP.

LECTURE II.

(*Concluded from page 89.*)

Let us now enquire whether we shall be any better off with a shunt-wound motor. The field excitation in such a machine does not depend on the current flowing through the armature as in a series machine, but it is simply the result of the terminal pressure; in other words, whatever current may be required by the armature for giving power, can be, and is, in fact, supplied by the source of current, without in any way affecting the field excitation. If the terminal pressure varies, the excitation and the field strength must also vary; but a variation in the working current will not directly influence the field strength. It will, however, indirectly influence it by reason of a subsidiary effect, technically termed "armature reaction," and this I shall touch upon shortly. For the present we neglect it, and assume that the curve F correctly represent the field strength as a function of the terminal pressure. In machines having wrought-iron magnets, this first part of this curve is almost a straight line, and in this region the field strength is consequently very nearly in direct proportion to the terminal E.M.F. To work the motor at this part of its curve, all we have to do is to supply it with current at a pressure sensibly lower than that for which it is designed. In good machines the resistance of the armature is very low, so that only a few per cent. of the voltage supplied is lost in resistance, even when the maximum current flows through the armature. If, therefore, we work the motor considerably under its power, the armature loss will be almost negligible—that is to say, the counter E.M.F. will be very nearly equal to the supply E.M.F. Now if you look at the formula for E.M.F., you find that on the left you have a value very nearly equal to the supply E.M.F., and on the right you have a constant multiplied with the product—field strength and speed. But the field strength under our special conditions of working is proportional to the supply E.M.F., and as you thus have the supply E.M.F. on both sides of the equation, it cancels out.

* Cantor lectures delivered before the Society of Arts.

and you find that the speed, multiplied by a constant, is equal to unity. This of course holds good for any supply E.M.F. within the straight part of the curve; and we find, therefore, that the speed has a definite value which is independent of the supply E.M.F. We have here arrived at a very remarkable result. It is this, that if you work a shunt motor underloaded and at a lower pressure than it is designed for, you may vary this pressure within certain limits without either altering the speed or the power given out.

As, however, the motor must be large in proportion to its work, the practical use of this remarkable property of shunt motors is limited. What users of these machines want to do is not to get little power out of them, but to get as much power as possible, and, in many cases, more than was intended by the designer. Let us then see how we stand in the matter of speed and power regulation when we work the machine throughout the whole range of output for which it is designed. First, as to speed. Let us assume that the machine is working at a certain speed giving off a definite amount of power, and suppose we wish to increase the speed. How shall we do it? The E.M.F. formula tells us. You see that the field strength and speed occur on the same side of the equation. This means that the one can only be increased at the expense of the other. If we want the machine to run faster, we must weaken its field; if we want it to run slower, we must strengthen it. The variation of field strength is most conveniently brought about by a variable resistance in the magnet circuit. I have such a resistance in the shunt circuit of the machine before you, and can show you, by an experiment, this method of regulating the speed.

In this experiment we have altered both the speed and power, because, by running faster, we have obtained more current from the second machine and a brighter light in the lamp. Let us now see whether it is possible to keep the speed constant, and yet vary the power. Bearing in mind that the dynamo is a reversible machine, and drawing a parallel between a shunt dynamo and a shunt motor, we conclude that there should be no difficulty in doing this. The fact that a shunt motor is an almost self-regulating machine has been first pointed out by Mr. Mordey in an article which appeared in January, 1886, in the *Philosophical Magazine*. Mr. Mordey's reasoning was somewhat as follows: We know that a shunt dynamo will, if driven at a constant speed, give an almost constant terminal pressure, no matter how the current may vary. Consequently a shunt motor, if supplied with current at constant pressure, will run at an almost constant speed, no matter how the load may vary. On testing his theoretical deduction by actual experiment, Mr. Mordey was able to completely verify it. In one set of experiments the supply current was kept at 140 volts, and the load on the motor was varied from 1·8 h.p. to 16·3 h.p., yet the speed only varied by 3 per cent.; and a similar result was obtained with the same machine at a supply pressure of 100 volts. Mr. Mordey stated in his paper that the magnetic distortion of the field was nil, or, as we might also term it, that the armature reaction was negligible. It is, however, easy to see that, even if the armature reaction is sensible, we can yet obtain very fair regulation, provided we take care to have in the armature circuit such a resistance that the voltage loss due to the resistance is about equal to that due to armature reaction.

To explain this, I must first say a few words about armature reaction, a phenomenon which may perhaps not be familiar to all of you. The current flowing through the armature, transforms it into an electromagnet, which, to a certain extent, opposes the flow of magnetic lines emanating from the field magnets. This is the case both in dynamos and motors, though not quite to the same extent. The larger the current, the larger is this opposition which the armature offers to the field magnets; and it is the field strength which remains, after making allowance for this opposing magnetic force, which is productive of E.M.F. To calculate correctly the counter E.M.F. of a shunt motor we must, therefore, not assume the field strength in our E.M.F. equation to be constant, as I have done hitherto; but we must assume that it decreases slightly as the armature current increases. Graphically, this is represented in Fig. 5, where the current flowing through the armature is measured on the horizontal, O C, and the field strength is represented by the inclined full line above. If there were no armature reaction the field strength would be given by the dotted horizontal line. If the speed is to remain constant, the counter E.M.F. must be proportional to the field strength; and, by suitably altering the scale (with which we measure the ordinates in the diagram), we can take the top line to represent counter E.M.F. I have accordingly marked it E E.

The vertical distance, O E, represents now the supply E.M.F., and when the motor is running light, this is, of course, equal to the counter E.M.F. Now, let a load be thrown on, causing a considerable increase of current. The counter E.M.F. need now not be quite so large as before, since part of the supply E.M.F. has been already absorbed by the resistance of the armature circuit, and the counter E.M.F. need only balance *the remainder*. We find thu[illegible] [illegible]ly condition [illegible] constant voltage requires the counter E.M.F. to become l[illegible] the power demanded from the motor increases. At the [illegible] time the working condition of constant speed can [illegible] attained by a lowering of the counter E.M.F. as the cur[rent] increases; and it is therefore perfectly obvious that if [the] lowering of the counter E.M.F., as determined by either [con]dition, is the same, we must have constant speed at [vari]able power—that is, a self-regulating motor. Generally, the [line] E E in the diagram representing counter E.M.F. is not [quite] straight, but slightly curved, presenting the concave side t[o the] axis of abscissæ, whilst the line representing resistance [loss] through armature is of course quite straight. If we so d[esign] the machine as to get exactly the same speed when run[ning] quite light and fully loaded, the speed will be slightly l[ower at] half load, but the difference can only be very small. I am a[ble] to show you this property of the shunt motor to be almost [per]fectly self-regulating by means of the apparatus here before y[ou].

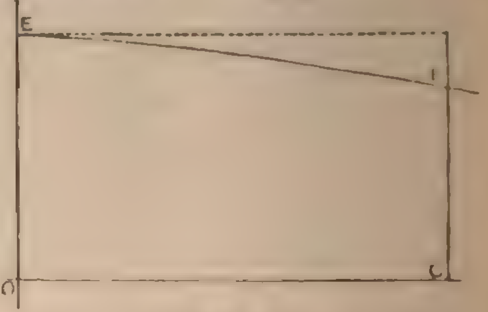

Fig. 5.

Thus, you see that the shunt motor is an excellent m[achine] for keeping the speed constant when worked on a con[stant] pressure circuit. The only drawback to its employment is t[hat] a resistance must be inserted into the armature circu[it at] starting; but this may be done automatically by placing [the] resistance permanently in circuit, and causing it to be sh[ort] circuited by means of a centrifugal regulator fixed to the a[rma]ture shaft, and so arranged that when the speed has attai[ned a] certain value the balls fly out and close a switch. Such [an] automatic device is also of value in case the motor should [be] overloaded. If this should happen the speed will drop, and [the] resistance will be automatically reinserted, keeping the cu[rrent] within safe limits. By these means a customer of an ele[ctric] light company is prevented from taking from the mains [more] current than he has contracted for.

Before leaving the subject of speed regulation on const[ant] pressure circuits, I must briefly allude to a system in us[e on] electric tramways. Motors for tramcars are not required to [run] at a constant speed, but they are required to have a wide r[ange] of torque. At starting, or when running up hill, the speed [may] be low, but the static effort must be great. These motors [are] therefore generally series wound, and provision is made [by] means of a compound switch for inserting a larger or sma[ller] number of field-magnet coils, so as to vary the field stre[ngth] according to requirements. The arrangement of the mo[tors] under the floor of the car is shown in the diagrams on the w[all], which represent respectively the cars of Mr. Reckenzaun, [the] Electric Engineering Company, and the General Electric Po[wer] and Traction Company, but time will not permit of my g[oing] into details of the various designs.

When current is supplied to the motor not from a gen[eral] system of mains, but from a special generator, serving no o[ther] purpose, the regulation of speed and power can be effe[cted] equally well by series, compound, or shunt machines. As reg[ards] the latter, I need not go into details, as this case is really inclu[ded] in the case of supply at constant pressure, which I have alre[ady] fully treated. After what I have said about this case, you [will] also readily see that compound-wound motors with the m[ain] coils demagnetising are equivalent to shunt motors with h[igh] armature reaction, and that, in fact, a shunt motor with v[ery] small armature reaction—such, for instance, as a multip[olar] machine—may be made self-regulating by the addition [of] demagnetising main coils on the field magnets. I shall later [on] give you details of a large transmission plant carried out [on] these lines, and need therefore not go further into the sub[ject] now. There remains then only the plain series motor to [be] considered.

In this case both the generating and the receiving dyn[amos] are series wound, and it is easy to see that by suitably desig[ning] these machines we can bring it about that the motor will ru[n at] a constant speed under varying loads if the generator is [kept] running at a constant speed at all times. Let the two cu[rves] in Fig. 6 represent the E.M.F. characteristics of the [two] machines, the upper curve referring to the generator and [the] lower to the motor. These curves give the useful E.M.F. a[fter] deducting armature reaction, and refer of course to cons[tant] speed in each case. The current flowing through the circu[it is] that which we obtain by dividing the difference between [illegible]

inates of the two curves by the total resistance. The resist-e is of course a constant, and the curve representing current l difference of E.M.F. is therefore a straight line, O R in the gram. The vertical length, C R, gives the voltage loss with urrent, O C, due to resistance, and this must be equal to the tage difference, 1, 2, between the curves. This determines, refore, the speed of the motor for that particular current. ppose the lower curve is the E.M.F. characteristic that particular speed. Now let us throw some of the d off, then the current will assume a smaller value, say O C'. e voltage loss is now C' R', and the voltage difference 1' 2'. the E.M.F. characteristic fits this new working condition, n 1' 2' must be equal to C' R', and the speed will remain the ne as before. We thus find that if we so design the chines that the difference between their E.M.F. charac-istics at any working point is equal to the voltage loss by istance, we obtain a perfectly self-regulating system of power

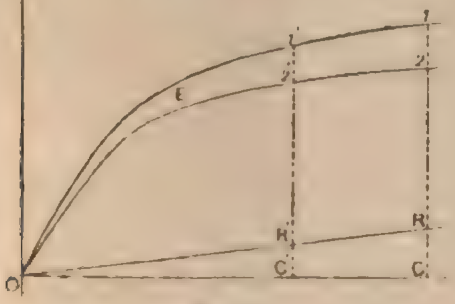

FIG. 6.

nsmission. Most of the transmissions now at work have been igned by taking advantage of this very valuable quality of ies machines, but I must state at once that, in actual practice, case is not quite so simple as I have here represented it. e of the difficulties met with is that we cannot always get two characteristics to fit each other exactly over the whole ge of output; another difficulty arises from their being erally a slight difference between the ascending and cending characteristics; but the most serious obstacle quick and perfect regulation is the self-induction the field magnets, especially if the machines are ge. The self-induction prevents the rapid response of machine to the other, which is required to make the ulation absolutely perfect. A sudden change of load cannot followed immediately by a corresponding change in the ver supplied to the motor, as time is required by the magnets settle down into the new working condition; and during the nsitory period, which may last many seconds, there is a ging of power to and fro which creates fluctuation of speed. mitigate this evil, Herr Dobrovolsky, of the Berlin Electric npany, has devised a plan by which a kind of electrical aper is applied to the generator in the shape of a non-uctive high resistance placed across the terminals of the gnet coils as a shunt, and left there permanently. Any ormal wave of E.M.F. which might otherwise disturb the king of the motor or endanger the insulation of either chine, spends itself in heating this resistance, and the dis-bance quickly subsides.

THE LINE.

pass now to the consideration of the line, a subject of great ortance, especially in long-distance transmission, since in se cases the cost of the line forms a very large item in the l cost of plant. You are all familiar with Sir William mson's law for greatest economy in conductors. Briefly, reasoning on which this law has been developed is as ows: The annual cost of power delivered is made up of two ns. First, the cost of the power only, and secondly, the rest on the capital outlay. The cost of power includes that ount which is wasted in heating the conductor. If I there-e wish to work with the greatest economy, the sum of annual rest on the capital outlay and cost of power wasted must be inimum; and this condition is attained when the two are al. Profs. Ayrton and Perry were the first to question the ctical applicability of this law. In a paper read by them ore the Institution of Electrical Engineers in March, 1888, y showed that under certain conditions better economy can obtained by departing from, instead of following, Sir William mson's law. I do not propose to give you quotations from ir paper, which is highly mathematical, but I will endeavour ut the subject before you in a different way, requiring only y little mathematical treatment.

irst of all, let us see in a general way what Sir William mson's law really means. It supposes that the annual trical horse-power has a definite value at any place reached he conductor. This is generally assumed for the distri-ing system as carried out from central stations. Whether a omer lives 100 yards or 500 yards from a central station, company charges him the same for the current. But the

MOST ECONOMICAL CURRENT FOR ELECTRIC POWER TRANSMISSION.

D	Distance in miles.
a	Section of conductor in square inches.
E	Terminal volts at generator.
e	Terminal volts at motor.
HP_g	Brake horse-power required to drive generator.
HP_m	Brake horse power obtained from motor.
c	Current in amperes.
	Efficiency of generator, 90 per cent.; efficiency of motor, 90 per cent.
g	Cost in £ per electrical horse-power output of generator.
m	Cost in £ per brake horse-power output of motor, including regulating gear.
$G = \cdot 9\, g\, HP\, g$ ...	Cost in £ of generator.
$M = m\, HP_m$ ...	Cost in £ of motor and regulating gear.
$t = 18 \cdot 2\, D\, a$	Weight in tons of copper in line.
K	Cost in £ per ton of copper, including labour in erection.
s	Cost in £ of supports of line per mile run.
p	Cost in £ of one annual brake horse-power absorbed by generator.
q	Percentage for interest and depreciation on the whole plant.

$$\text{Capital outlay} = g\,\frac{E\,c}{746} + m\,HP_m + D\,s + \frac{1 \cdot 6\,K\,D^2\,c^2}{E\,c - 830\,HP_m} = A.$$

$$\text{Annual cost per brake horse-power delivered} = q\,\frac{A}{HP_m} + p\,\frac{HP_g}{HP_m}$$

$$\text{Put } B = \frac{E\,p}{670} + q\,\frac{E\,g}{746}.$$

$\gamma = \frac{830}{E}\,HP_m$, the current which would be required if the line had no resistance,

and $\beta = \gamma^2\,\frac{E\,B}{1 \cdot 6\,q\,K\,D^2 + E\,B}$; then the most economical current at the given voltage, E, is

$$c = \gamma\left(1 + \sqrt{1 - \frac{\beta}{\gamma^2}}\right)$$

$$c = \gamma\left(1 + \sqrt{\frac{1 \cdot 6\,q\,K\,D^2}{1 \cdot 6\,q\,K\,D^2 + B\,E}}\right)$$

For very long distances the term under the square root approaches unity and the most economical current the value 2γ; from which it follows that under no circumstances will it be economical to lose more than half the total power in the line.

assumption is not, strictly speaking, correct. To see this, let us suppose that the cost to the company of putting an annual horse-power into their mains is £20, and they get £30 for every annual horse-power taken by the customer. Now, if I lose 1 h.p., shall I be right in writing off this loss at £20. Clearly not; for if I had not lost this particular horse-power, I might have sold it for £30. But there is another way of looking at this. You might say that the £10 difference between the cost and selling price of power represents profit and interest of plant and mains, and that, therefore, the lost power should be debited at net cost. To this I reply that my object is not to put power into the mains, but to take power out, or, rather, enable my customers to take power out, for which they will pay me; and so we might keep arguing the question, without ever coming to a definite understanding. Now, if we cannot settle such a simple problem by common-sense reasoning, there must be something wrong in our premises; and, in this case, it is not difficult to see where the hitch is. It is in the assumption that the power has a constant value. In reality, this is never the case. If it were the case—that is to say, if 1 h.p. had the same value at the motor end as it has at the generator end of the line—it would be perfectly useless to establish a transmission plant; it would be like carrying coals from Cardiff to Newcastle. It is only because the power has a great value at the motor end of the line, and a small value at the generator end, that it will pay us to lay out capital in plant, and incur the risk of working it.

The correct way of treating this problem is, therefore, to take into account the cost of the power, both at the generating and at the receiving station. We must, further, take into account not only the interest and depreciation of the line, but also the interest and depreciation of the machinery at either end; and in estimating these items we must know at what voltage the plant is to work, and what total power is required; for the prime cost per horse-power depends very materially on the total power and voltage. To make this clear, if I want to reduce the capital outlay on the line, I must work at high voltage, and with a large energy loss. This means that I must put down a larger generator than would otherwise be required, and, moreover, one that gives an high-pressure current. It is thus quite possible that what I save in the line I shall have to expend at the generating station, to say nothing of the increased charge for waste power, and the greater liability to have a breakdown owing to high voltage.

You see this problem is a very complicated one, and

Thomson's law, which says nothing about voltage or cost of machines, will not fit it. It is, however, possible to amend this law, so as to obtain at least an approximate solution. The premises on which the formula has been deduced are as follows:

Conditions given.—Annual value of brake horse-power at generating station; voltage at generator terminals; brake horse-power required at motor end; distance of transmission; cost per horse-power of machines and regulating appliances at the given output and voltage; cost of conductor, per ton of copper erected, interest, and depreciation of whole plant.

Data required.—Working current, brake horse-power at generating station, mechanical efficiency, voltage at motor, total capital outlay per brake horse-power delivered, and cost of annual brake horse-power.

The efficiency of each machine is assumed to be 90 per cent. The formula gives only the current, but the other data can be found by very simple calculations which need no explanation. The cost of supports for the line per mile, whether overhead or underground, can be taken as constant—that is, not depending on the exact current within the limits—which can easily be foreseen in each case; and it therefore does not enter into the formula for the current. Interest and depreciation I have taken the same for all parts of the plant, so as to avoid too great a complication of the formula. If you now work out by the aid of the current formula the same transmission problem for different voltages, you will find that there is one particular voltage for which the annual cost of the brake horse-power delivered at the motor end of the line is a minimum; and provided this voltage is within reasonable limits, it ought to be adopted. When making such calculations, you will find that the greater the cost of power at the generating station, the higher is the most economical voltage, this voltage also, of course, increasing with the distance.

Each case must be worked out with due regard to local conditions, and nothing in the shape of cut and dried rules or figures can make this work superfluous. On the other hand, it is very desirable to collect information as to the cost of works which have actually been carried out, and by the liberality of Mr. Brown, the engineer to the Oerlikon Works, Switzerland, I am able to place before you some figures of this kind which are contained in the following table. The figures give the whole capital outlay for the electrical parts of some of the power transmissions erected by this firm.

COST OF TRANSMISSION OF POWER PLANT.

Distance in miles.	H.P. delivered.	Speed of machine.	Cost in £			Total cost.* £	Cost per H.P. £

* This includes regulating apparatus, instruments, posts, insulators, lightning arresters, erection, and supervision.

LEGAL INTELLIGENCE.

ORIENTAL TELEPHONE COMPANY.

Enlarging the Scope of the Company's Operations.

In the Courts last week Mr. Cozens-Hardy, Q.C., appeared before Mr. Justice Romer for this Company, which had presented a petition for the confirmation of a special resolution enlarging the scope of the Company's operations. He said the Company was formed for the purpose of carrying on telephonic communication in the East, and was engaged in very large operations, partly in its own name and also by supporting and holding shares in other companies carrying on operations in Bombay, Bengal, China, and Japan, etc. Some of these companies had power by their articles to carry on other electrical business, and the Company itself having an expensive and skilled staff, was frequently applied to to supply electricity for lighting and other purposes, but was advised that they could not do so under the *existing memorandum*.

Mr. Justice Romer pointed out that in this case the name would require to be altered. When that was done he should be prepared to sanction the resolution.

COMPANIES' MEETINGS.

CROMPTON AND CO.

The third annual general meeting of this Company was held at the Cannon-street Hotel on Wednesday afternoon, Mr. R. E. B. Crompton, one of the managing directors, in the chair.

The **Secretary** (Mr. Reeves) having read the notice convening the meeting,

The **Chairman** said: Gentlemen, you have had the report (this was given in our last issue), and I assume that it may be taken as read. I have now to move that the report of the Directors and the audited statement of accounts for the year ending 31st March, 1891, be, and the same are, hereby approved and adopted. With respect to the statement of accounts, I think the shareholders will agree with me that the balance of net profits, amounting to slightly over £13,000, shows a satisfactory rate of increase on the balance of the previous year, and justifies the remarks I made to you at the last year's meeting as to the probable steady increase of this Company's business. During the current year we have executed several important contracts, and our turnover has largely increased. But, as I explained to you last year, these large contracts were taken at fixed rates of profit. At the same time these contracts constitute a very safe and satisfactory feature of the Company's business—a feature we hope to see extended during the current year. Among the important orders we have in hand, is one for lighting the city of Pretoria, which is the capital of the Transvaal. In connection with this contract, Mr. J. F. Albright has visited South Africa recently, and will explain to you that there is every probability of our doing a large business there. Contracts are in progress for important central stations on the Continent, any one of which may be decided shortly, and any one of which will result in a large increase in our turnover. Negotiations are also in hand for several large towns in England. We think we stand a good chance of securing a fair proportion of these orders, and these will secure a safe and fairly remunerative profit for our shareholders. A firm like ours, which has always to occupy a leading place among manufacturers, has to keep abreast of improvements, and, in fact, we have to introduce improvements. During the last year we have perfected a system of electric railways, and succeeded in carrying out for the Southend Local Board an exceedingly successful example of the modern electric railway, which has received the highest encomiums from everyone connected with it, the consulting engineer (Dr. John Hopkinson) himself saying that he had never passed a final certificate with so much satisfaction. Another cognate branch of our business during the year has been electrical underground haulage for mines. We have recently carried out two very large sets of such haulage with complete success. In both cases we transmitted upwards of 100 h.p. The last case was one in South Wales. It was successfully started last Friday close to Merthyr Tydfil. I may say in connection with this that colliery managers who witnessed the experiments said we could book enough orders to keep our works going with this alone. These installations don't show in the accounts under consideration; they come into the accounts of the present year. I ought to mention, in connection with the success of electric haulage, that a great deal is due to our South Wales agent, Mr. J. C. Howell. We have expended a considerable amount on capital account, partly in increasing our buildings and fitting up our works at Chelmsford, but partly in fitting up Lillie-road works in London. These are of very great use to us, and we should not be able to carry out our London work without them. Coming to the statement of accounts, I would refer to the question of debentures. At the last meeting I informed you we had decided to issue the second £25,000 out of £50,000, and we offered them to our shareholders; but the response was not as satisfactory as we expected it would be. At the date of this present report only £31,050 debentures had been subscribed—or a little over £6,000 since last year's meeting. At the present moment we have over £15,000 of these debentures to be placed. We have not pushed the issue of them by advertising, but we now find it really necessary that the Company should have this additional capital, and the Directors would be glad if shareholders would send in their applications so as to close the list by subscribing for the balance. The debentures are amply secured, and as the total interest on the issue is only £2,500, and the profit is now £13,030, there is little doubt but that the debenture holders will receive their money in the future as in the past. To exemplify the use of capital, I may say that we were able last year to secure for the Company, by prompt payment of accounts, an extra profit in the shape of cash discount; and that this sum was in excess of the total amount required for the whole of the debentures then issued. With regard to the distribution of the net profit, you will see the Directors propose, after setting aside £500 for bad debts, to pay a dividend of 3s. 6d. per share, making 7 per cent. per annum on the preference shares, and 5s. 6d. per share, making, with the interim dividend, a total of 8 per cent. per annum on the ordinary shares. I may say that the good feeling which I stated in my speech last year existed between ourselves and our staff of workpeople still continues. I have to thank the staff for the satisfactory way in which they have worked during the past year, and the works' managers for the immense pains they have taken in

promoting the working of the men's sick clubs. I shall have great pleasure in answering any questions from shareholders present. I conclude by moving the resolution mentioned above—viz., that the report and accounts be received and adopted. Mr. Albright, who has had a long business tour round the world, returned home two days ago, and will give you a statement as to the results of his journey.

The resolution was seconded by **Mr. Carleton F. Tufnell**, and carried unanimously.

The **Chairman** moved the payment of the dividends on the preference and ordinary shares, which was carried. He then informed the shareholders that since the last meeting they had lost a very valuable director in the person of Sir Charles Grant, who, owing to his no longer residing in London, had regretfully given up his directorship. The Board had appointed Mr. H. H. J. W. Drummond, who had served some time and proved of valuable assistance to them. Quite recently they had secured the services of another extremely valuable director, Viscount Emlyn, who was on the Board of the Great Western Railway. The acquisition of this gentleman gave them very great strength, and he was experienced in the management of large bodies of men. His railway connection could not fail to be of value in forwarding the cause of the Company, while he had very greatly increased their influence in the West of England. He moved the approval and confirmation of the appointment of these Directors.

This was seconded by **Mr. G. S. Albright**, and carried unanimously.

Mr. Gibson, the retiring director, having been re-elected,

Mr. J. F. Albright said that he had been alluded to as having just returned from an extended trip round the world, and though he had not had time to think out any elaborate statement of his travels, he would, in a few words, give them a general impression of what he had seen. He first visited Canada, and met there the agents they had recently appointed. He had every reason to be satisfied with the agents, and he believed that the orders they had sent home since his visit had been of considerable importance. He also visited the United States, but, as they were probably aware, owing to the extremely high tariffs, it was almost impossible to do any business there, although they were doing a certain amount. After that he went to Australia and saw their Company which had been established there. His impression of the country, and the way in which it was being worked, was that, although there were many things to be improved upon, still they were better represented than any other English or European firm; probably only one firm was in a better position than they were, and that was an American one. Of course, in Australia the prospect of business was considerable, but, at the same time, it could only be done by people who knew the country well and were well known in the country; and that was one reason why they might consider they were well represented there — the people were old-established residents. He was only a short time in India, but he arranged for their being represented by an old-established house in Calcutta —the oldest house there, and also one that had done more electrical work than any other. From India he went to the Mauritius. Here there was no work left to be done, and no money to pay for any. Leaving the Mauritius he next went to Natal, and up to Pretoria, where he made the final arrangements for lighting the town. The fact of their having obtained that contract was likely to be the means of establishing for them a very considerable and valuable business throughout South Africa. He had also made arrangements for their being represented in the Transvaal, and was asked to report to the Town Council of Durham and met representatives of the Town Council of Capetown. As a result there was a fair prospect of business being done. Altogether he might say that having been round the world he was better able to meet the questions they might have to deal with, and therefore he had the greatest satisfaction in having made the trip.

The re-election of the Auditors having been unanimously carried, a hearty vote of thanks to the Chairman brought the proceedings to a close.

MANCHESTER EDISON-SWAN COMPANY.

Report.

The Directors beg to submit the accompanying balance-sheet for the year ending 30th May, 1891. The net profit, including last year's balance, amounts to £2,292. 10s., which it is proposed to appropriate as follows:

To payment of dividend at 5 per cent. per annum ...	£1,000 0 0
To payment on account of 5 per cent. cumulative preferential dividend on the "A" shares at the rate of 1¼ per cent. on £40,000 (the original paid-up capital of the Company), for the year ending 31st May, 1883	500 0 0
Balance to be carried forward	792 10 0
	£2,292 10 0

If the above be approved, the dividend warrants will be issued on 1st August, 1891. Since the last general meeting the Directors have had to deplore the loss, by death, of their esteemed colleague, Mr. Edward Cross. The Directors have filled this vacancy on the Board by the election of Mr. Frederick B. Ross as a director of the Company. Mr. W. P. James Fawcus, the Company's manager, has been elected to fill the vacancy on the Board caused by the resignation, through ill-health, of Mr. J. R. Williamson, and the shareholders are asked to confirm his appointment as director. Mr. Frederick B. Ross retires in accordance with the Company's articles of association; he is, however, eligible, and offers himself for re-election.

The ninth ordinary general meeting of this Company was held on Wednesday in Manchester, Mr. V. K. Armitage, chairman, presiding.

The **Chairman**, in moving the adoption of the report, explained that the dividend of 1¼ per cent. on the £40,000 was on the original capital, which was entitled to 5 per cent. cumulative dividend before any money out of profits was paid on the B shares to the present Company, and now, for the first time, they were able to come back to 1883 and pay something on account of the £40,000. The amount it was proposed to pay was £500, and it came to 1¼ per cent. The report and accounts showed that they had made a profit of £1,645, and adding to that £647. 6s., balance from last year, they had at their disposal £2,292. 10s. Since the extraordinary meeting of the Company was held some months ago, the Directors had tendered for one or two large installations, but they did not see that they would make very much out of them if they got them, and so they did not persevere with them. They had come to the conclusion that their money might very well be spent in another quarter altogether. Some 18 months or two years ago, when Mr. Williamson, who was then the managing director of the Company, went out to Sydney for the benefit of his health, five or six of them, who had confidence in his trustworthiness and ability, joined together and formed a little company with a nominal capital of £5,000, of which £2,500 was called up. Well, Mr. Williamson had not been out in Australia 12 months before orders were pouring in upon them, and they foresaw a time when the capital of the little company would be as a mere drop in the bucket. It was then suggested that instead of allowing the money of the Manchester Edison-Swan Company to lie idle at the bank, it would be well to invest it in shares in the Williamson Company, and after considerable deliberation with those directors of the Edison-Swan Company who were not in the smallest degree interested in the Williamson Company, they arrived at the unanimous conclusion that it was the best thing they could do; £2,500 of the Company's money had accordingly been invested on advantageous terms in the Williamson Company. Mr. Williamson had a great deal of business in hand, and when that was got out he had good ground for hoping that he would be able to get more. With regard to the prospects of the Company, he could add little to what he had said at previous meetings. They had tendered, together with a number of other firms, for the lighting of the Manchester Town Hall, and they were hopeful that their tender might be successful. They sincerely believed that when they had got the Town Hall lighted with electricity it would be such an improvement on the present arrangement that the Corporation and the citizens would be encouraged to use the electric light more freely. In conclusion, the Chairman assured the shareholders that the price at which the shares of the Company were knocked about on the Stock Exchange did not by any means represent their intrinsic value. Unless to people who were buying or selling the shares for gambling purposes, it did not matter one straw at what price they stood on the Stock Exchange. The great thing was, what did the shareholders get at the end of the financial year on the amount of money they had invested? He thought that was the way in which to judge the *bona fide* value of the shares. He moved the adoption of the report and accounts.

This was seconded by **Mr. I. C. Waterhouse**.

In reply to a question by Mr. C. Agnew, the **Chairman** stated that the Directors were acting quite in accordance with the articles of association in entering upon the Australian business. In the past, so long as they could make a profit, they had not hesitated to do business in any part of the world.

Mr. Becker, while not seeking to cast a doubt on the probable profitableness of the Australian business, said he thought the Directors had been somewhat unceremonious in launching out into such work without consulting the shareholders.

The **Chairman** defended the action of the Directors, and the resolution for the adoption of the report was carried unanimously.

The dividends recommended in the report were declared payable, and the thanks of the shareholders were accorded to the Directors, to whom a sum of £150 was voted for their services.

COMPANIES' REPORTS.

TELEPHONE COMPANY OF IRELAND.

The report of the Directors for the year ending December 31, 1890, states that inasmuch as the articles of association require that the accounts shall be made up to a date not more than four months before the annual meeting, a supplementary statement of accounts is also presented herewith for the half-year ending June 30, 1891. The negotiations for the raising of additional capital have now been satisfactorily concluded. The Company is now entitled to some reduction of the instrument royalties, and, in accordance with the terms of the agreement between the United Telephone Company and this Company, the amount of such reduction will be settled by arbitration. The accounts now submitted are therefore subject to adjustment, according to the decision of the arbitrator. The amount standing to the credit of the net revenue account as upon December 31, 1890, including the balance brought from last account, amounts to £4,950, against £4,450 for the year 1889. Out of this sum there has been paid an interim dividend upon the preference shares for the half-year ended

June 30, 1890 (£1,138 paid in July last), leaving an available balance of £3,813, as shown in the balance-sheet, which the Directors propose to allocate as follows: For the payment of the debenture interest, £49; for the payment of balance dividend upon the preference shares for the second half of the year (£1,153); and to place to the credit of the reserve fund £464. 13s. 6d. (being 10 per cent. of the net profits of the year), carrying forward the balance of £2,146 to credit of the current year.

UNITED RIVER PLATE TELEPHONE COMPANY.

The report of the Directors for the year ended March last states that the result, after meeting expenditure and debenture interest, was a profit of £38,480. 14s. 4d., from which £36,049. 0s. 8d. has to be deducted for loss on exchange, leaving a net profit of £2,431. 13s. 8d., increased to £4,805. 10s. 2d. by the addition of the sum brought down. The Directors recommend that £768. 7s. 8d. be applied in writing off one half of the taxes suspense account, £2,000 be written off for bad and doubtful debts in the River Plate, and that the balance of £2,037. 2s. 6d. be carried forward.

ANGLO-AMERICAN TELEGRAPH COMPANY.

The report of the Directors for the first half of the current year has been issued. Second quarterly dividends of 12s. per cent. on the ordinary stock and of £1. 4s. per cent. on the preferred stock are recommended, leaving £527 to be carried forward. It is stated that the appeal of the Anglo Company was argued before the French Council of State on May 1 last, and the decision of the Council of Prefecture was reversed in the Company's favour. The case will now be heard by the Court of Appeal on the question of damages, and it is expected that judgment will be pronounced soon after the termination of the long vacation.

NEW COMPANIES REGISTERED.

Home Telephonic Company, Limited.—Registered by H. P. Spottiswoode, 32, Craven-street, Charing Cross, with a capital of £500 in £5 shares. Object: to contract for the carrying on of any telephonic, telegraphic, or any other electrical business.

Tayler-Smith Electric Company, Limited. — Registered by Cave and Co., 4, Fenchurch-street, E.C., with a capital of £6,000 in £10 shares. Object: to acquire the undertaking of Thomas Tayler-Smith, 4, Circus-place, London, and to carry on thereat the business of an electric engineer and electrician in all its branches. The first managers of the Company are T. T. Smith and Major Keppel Stephenson. Neither qualification nor remuneration specified.

CITY NOTES.

Cuba Submarine Telegraph Company.—For the past half-year the Directors recommend a dividend at the rate of 8 per cent. per annum.

City and South London Railway.—The receipts for the week ending 25th July were £686, against £689 for the week ending 18th inst.

PROVISIONAL PATENTS, 1891.

JULY 20.

12285. **A magneto advertising or displaying device.** Albert Augustus Goldston, Post Office-buildings, Middlesbrough.

12286. **Economic electromotor and motive power.** Claud Salusbury Foljambe Mellor, 8, Lyric-chambers, Whitcomb-street, Haymarket, London.

12296. **Improvements in apparatus for the manufacture, by electrolysis, of tubes and other articles of circular section.** Alexander Stanley Elmore, 28, Southampton-buildings, London.

12313. **Improvements in electric batteries.** Edmund Christian Conrad Jungnickel, 323, High Holborn, London.

JULY 21.

12322. **Improvements in or relating to electrical welding.** Alfred Julius Boult, 323, High Holborn, London. (John H. Bassler, United States.) (Complete specification.)

12384. **Improved compound for insulating electric wires in general.** Murdoch Mackay, 166, Fleet-street, London.

JULY 22.

12415. **Improvements in and relating to quick hitching harness and its operation by electric current.** Francis Elliott Stuart, Volthurst, Twickenham.

12416. **Improvements in telephonic transmitters.** Alexander Marr, 70, Market-street, Manchester.

12455. **Improvements in electric locomotives.** Jasper Wetter, 433, Strand, London. (Henri Bonneau, France.) (Complete specification.)

JULY 23.

12484. **Improvements in telephonic switching apparatus.** Alfred Rosling Bennett, 22, St. Albans-road, Harlesden, London.

12491. **Improvements in the construction of rheostats and similar electrical instruments.** Charles Lawrence Baie and Woodhouse and Rawson United, Limited, 88, Queen Victoria-street, London.

12503. **An improved electric ear-ring for curative and remedial purposes.** Edward Owen, 37, Chancery-lane, London.

12525. **Electrical steering gear.** George Sylvester Grimston and Alfred Herbert Dykes, 28, Southampton-buildings, London.

12529. **Improvements in means for distributing electric currents.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

12531. **A new or improved apparatus for producing pictures upon a screen in stereoscopic relief by means of electricity.** Désiré Bouchard, 35, Southampton-buildings, London.

12535. **Improvements in switches for electric installations.** Alfred Vincent Newton, 6, Breams-buildings, London. (Alfred Swan, United States.)

12540. **Dynamo-electric machines.** Hermann Cuénod, Ernest Sautter, and Georges Hochreutiner, 24, Southampton-buildings, London. (Date applied for under Patents Act 1883, sec. 103, December 31, 1890, being date of application in Switzerland.) (Complete specification.)

12541. **A system for the automatic regulation of the position of the brushes of dynamo-electric machines, magneto-electric machines, and electric motors.** Hermann Cuénod, Ernest Sautter, and Georges Hochreutiner, 24, Southampton-buildings, London. (Date applied for under Patents Acts, 1883, sec. 103, December 31, 1890, being date of application in Switzerland.) (Complete specification.)

JULY 24.

12592. **Improvements relating to the manufacture or preparation of carbons for electric lamps or lighting apparatus.** Henry Harris Lake, 45, Southampton-buildings, London. (Lacombe and Co., France.)

12602. **Improvements in apparatus for measuring electric currents.** Hermann Aron, 6, Lord-street, Liverpool.

12605. **Improved means for securing terminals or binding-screws to plates or electrodes for electric batteries.** Henry Harris Lake, 45, Southampton-buildings, London. (Lacombe and Co., France.)

12611. **Improvements in or connected with the electrolytic deposition of copper.** Joseph Wilson Swan, 47, Lincoln's-inn-fields, London.

JULY 25.

12622. **An improvement in electric clocks.** Nugent Wells, 22, High-street, Newport, Mon.

12628. **Improvements in couplings and terminal connections for electric cables.** Joseph John Hargreaves and Ratcliffe William Nuttall, 20, Charles-street, Bradford.

12634. **Improvements in apparatus for electrical sound and sight signalling on railways and other lines of rail.** Archibald Drummond Macdonald and James Dodd, 25, Spellow-lane, Liverpool.

SPECIFICATIONS PUBLISHED.

1889.

6745. **Electrolysis of substances in fusion.** Kiliani. (Second edition.) 8d.

1890.

10624. **Dynamo-electric machines.** Scott. 8d.

12475. **Electrical smelting.** Taussig. 6d.

12713. **Electric mains.** De Ferranti. 8d.

13619. **Electric conductors.** Lineff. 8d.

13735. **Electro-metallurgical operations.** Hoepfner. 8d.

1891.

5963. **Electric "hooter."** Saunders and Brown. 8d.

8555. **Insulated electric conductors.** Thompson (Williams). 8d.

9435. **Electrical transformer.** Lauckert. 6d.

9436. **Electrical transformer.** Williamson. 6d.

NOTES.

Ballinskelligs.—The Direct United States Cable Company are about to commence at once the erection of a telegraph station at Ballinskelligs, a short distance from Valentia Island.

Prince of Monaco's Yacht.—This yacht, which is built and fitted up for scientific purposes, is lighted throughout by electricity. The installation has been carried out by Messrs. Woodhouse and Rawson.

Christiania.—The Christiania Corporation are inviting tenders for the erection of electrical works for about 12,000 lamps. Tenders are to be sent in, addressed to the Christiania Magistracy, by September 12.

New Cables.—The Western and Brazilian Telegraph Company, Limited, state that an expedition is now in Brazil laying new cables from Santos to Rio de Janeiro, Rio de Janeiro to Bahia, Bahia to Pernambuco.

Electric Railways in Italy.—A scheme, it is stated, is under consideration for the construction of an electric railway from Aosta to Pré-Sainte-Didier. The project will, if carried out, bring into existence the longest electric railway in Europe.

Electric Cars for Edinburgh.—The Lord Provost's Committee of the Town Council have under their consideration at the present time a proposal to experiment with electric cars in Leith-walk with the overhead wire method common in America.

Dalton Local Board.—A letter from Messrs. Nicholson and Jennings having been read at the Board's monthly meeting as regards lighting the streets with electricity, it was decided to refer the matter to the Highways and Lighting Committee.

Waterford.—A special meeting is to be held by the Town Council on September 1 to consider the advisability of applying to the Board of Trade for a license to supply electricity for public and private purposes. It is estimated that if a license is obtained the Council will approach the electric lighting company with a view to purchase.

Montrose.—The new hospital lately added to the asylum, the main building, and superintendent's house are electrically lighted. Manchester dynamos, driven by high-speed engines, are used, and, as a stand-by, a battery of accumulators sufficient to supply current to 50 lamps for 10 hours is installed. Altogether there are some 430 16 c.p. incandescent lamps.

Southampton.—Tenders are being invited by the Southampton Harbour Board for lighting the Royal Pier, Southampton, by electric light; also for providing and fixing two electrical cranes on the Town Quay, Southampton. Plans can be seen at the office of the engineer, Mr. J. G. W. Aldridge, 9, Victoria-street, Westminster. Tenders are to be sent in on or before the 24th inst.

Taunton.—The chairman of the gas company has been congratulating the shareholders upon the increased consumption of gas—and this in the face of competition with the electric light. This bears somewhat in favour of the views of many engineers that the introduction of the electric light should be favoured by the gas companies, in that it leads to the burning of more gas.

Electric Courting.—Paris, says the *Scientific American*, is laughing over a joke about an American inventor who is said to have patented an electric corset, calculated to bring about the reign of morality at once. If one of these articles is pressed by a lover's arm it emits a shriek like a railway whistle. The inventor claims to have already married off three of his daughters to their too backward lovers by the publicity thus thrust upon them!

Lampposts.—Electric Light: "Does your mother know you're out, Mr. Lamppost?" Lamppost: "Oh, yes; and you're to blame for it, too, you stuck-up thing, that you are." Electric Light: "Well, that's pretty strong, now; but then, you always were a little gassy, and a little, just a little, light in the head, you know." Lamppost: "You needn't talk, for you're a good deal lighter in the head than I ever was." Electric Light: "Oh, thank you."

Egremont.—At the monthly meeting of the Local Board, held last Friday, a report by the surveyor with regard to the utilisation of water power for electric lighting was considered, as was also other communications on the same subject. It was ultimately decided to adopt the motion of Mr. Simon, to the effect that a committee, consisting of Messrs. Smith, Bouch, Armstrong, Stout, and Davidson, be appointed to consider the letters, with power to call in professional assistance, if necessary.

Telegraph Engineers.—In reply to a question put by Mr. Webb in the House of Commons, the Postmaster-General stated that the engineering branch of the General Post Office performs work of a special character, and there does not appear to be any reason for making its classification uniform with that of another branch. The proposals affecting the pay of certain classes of engineering officers have been submitted to the Treasury, and are now receiving their Lordships' careful consideration.

Invention of the Electric Telegraph.—*Electricité* points out that Ampère and Babinet in 1822 mentioned that the deflection of a magnetic needle could be used to transmit signals to a distance. The application of it by Gauss and Weber, in 1833, published in 1834, at Gottingen, was considered by Gauss (Weber claiming no part of the discovery) as of only secondary importance. Our contemporary adds that it knows of no publication of actual results anterior to 1833, and if any exist would like to hear of them.

The Electric Light in Dentistry.—We now have the electric light to aid us in our dental operations, and I find, says Dr. Pruyn, by its use I can discover imperfections in cavities I have prepared that had previously escaped my attention. This is because the electric light gives a paler white light, and it is more intense than daylight. It is particularly so in that form of decay known as the white decay. You may prepare the cavity with the ordinary care, having it seemingly perfectly dry, and a magnifying glass will show you no imperfections, but with the aid of the electric light you find them.

Manchester Central Station.—The Cheshire Lines Committee have recently decided to erect an installation for the complete lighting of their central station, Manchester, and have placed the order for the whole of the plant with Messrs. Mather and Platt, of the Salford Iron Works. The plant will consist of incandescent lamps for the refreshment-rooms, ticket offices, and waiting-rooms, and of arc lights for the platforms. The plant is to be in duplicate throughout, and will consist of compound engines, Edison-Hopkinson dynamos for the incandescent lighting, and Manchester dynamos for the arc lighting.

Mercury Switch.—We notice that a "new type" of switch is described as in use at the works of M. Jacques Ullmann, in France, and others have introduced a similar arrangement for the avoidance of sparks at the point of

contact. This is the use of a tube of caoutchouc or glass with two points of contact and a little mercury. On turning it one way the mercury falls on the contacts and completes the circuit. It may be well to mention that this form of switch was one of several publicly shown many years ago by Mr. J. W. Swan for use with his lamps, and it is possible was even then not an absolutely novel type of switch.

Cork.—A special meeting of the City Council has been fixed for Friday, September 4th, when the following will form part of the business to be transacted—viz., to take into consideration notice given by the Cork Gas Consumers' Company intimating their intention to apply to the Board of Trade for a provisional order under the provisions of the Electric Lighting Acts of 1882 and 1888 to enable them to supply electrical energy within the municipal limits of the city of Cork, and in connection therewith to consider whether or not the Council will consent to such application, and if so, on what terms and conditions such consent will be given.

Grassot's Electrolytic Meter.—M. E. Grassot has recently invented an electric meter dependent on electrolytic action, which is novel and has points of advantage. In principle the meter consists of a silver wire of a certain length placed in a glass tube. At its lower extremity the bare wire dips about one-tenth of an inch into a solution of nitrate of silver; it is dissolved and descends gradually with a speed proportionate to the strength of current. The wire is coiled around a drum, whose motion is registered upon dials. The cathode is formed by a ribbon of zinc in the vessel. The diameter of the silver wire is 5 mm. The apparatus has given very satisfactory results.

Battery Terminals.—In battery circuits it is advisable, of course, to eliminate all unnecessary resistance, and that caused by corrosion of terminal contacts is not the least cause of trouble. Messrs. Hayes and Hibbard, of the United States Long-Distance Telephone Company, have recently perfected a method of making contacts to obviate this difficulty, and keep the resistance at the lowest point. The connections are always made by a soldered joint, the solder being previously placed on the wires to be connected, so that it is only necessary to twist them together and apply moderate heat, such as that of a candle or spirit lamp. Perfect connections are thus made with the greatest facility, and can be unmade with equal ease.

City and South London Electric Railway.—In view of the extension of the line from Stockwell to Clapham, for which the company already have parliamentary powers, they are making arrangements for a considerable extension of the generating plant at the Stockwell Station. They have placed the order with Messrs. Mather and Platt, of Manchester, for a fourth generating dynamo similar to the three at present working the line. The dynamo is to be of Messrs. Mather and Platt's patent Edison-Hopkinson type for an output of about 400 h.p. The company have also ordered a fourth engine from Messrs. John Fowler and Co., similar to the three existing engines, and have made arrangements for an increase of their rolling-stock.

Shoreditch Vestry.—At the last meeting of this Vestry the Parliamentary Committee, after carefully considering the question of notices served upon the Vestry, of intention of three private companies to apply in the next session of Parliament for provisional orders giving them the power to supply electric light and power in this parish, recommended that "the Vestry apply in the next session of Parliament for a provisional order empowering them to supply electric light and power in this parish, and to transfer and let out the work hereafter, if thought desirable, and that the vestry clerk be instructed to take the necessary steps to obtain the order." It was decided to call a meeting on the first Tuesday in September for this purpose.

Interior Conduits.—During the last four months a great advancement has been made in the application of the method we recently described of interior conduits in buildings for electric wires, as well as telephone and other wires, by the Interior Conduit and Insulation Company, of New York. Already arrangements have been made for 22 public and office buildings to be fitted with interior conduits for the distribution of about 58,105 incandescent lights, without counting many private residences which vary from 160 lights to 700 lights each, and two or three installations of concealed wires for about 150 arc lights. Four of the office buildings out of the 22 have wires for telegraph, telephone, message service, etc., run in conduits, and one has speaking-tubes.

Electricity for Engineers.—The *American Engineer* makes a sensible suggestion that in working-men mechanical engineers' clubs there should be an electrical night once a week or so, and states that it has arranged for a number of first-rate electrical engineers to give lectures and experiments. It goes on, however, in an extraordinary way, after such a practical suggestion, to give a page and a half of mixed science, poetry, and Scripture, apparently to prove that the walls of Jericho were probably overturned by pulsations in their substance generating an electrical current. It might be a good thing if these proposed simple lectures by first-rate men were published instead of such stuff, which could only serve to muddle working-men's ideas, if they knew nothing of the subject, or to look ridiculous in the eyes of those who did.

Taking the Cake.—A contemporary says: "No scientific body in the United States has so many millionaires as the American Institute of Electrical Engineers. At the top of the list is Alexander Graham Bell, whose profits on the telephone are represented by eight figures. Next comes Edison with a seven-figure fortune. Brush, of electric light fame, Elihu Thomson, and Edward Weston are more than millionaires. Frank J. Sprague was a junior officer in the United States navy six years ago. He is now living in the mansion which was built for the Grants. His company sold out to the Edison Company for £250,000, and half of it went to the inventor. Messrs. Bell, Thomson, and Weston are all of British birth. Most of these men were telegraph operators, and most of them began their experimenting and study without a dollar."

Trade Amenities.—At the Leeds Assizes a case was tried which is undoubtedly similar to what occurs too frequently in trade matters—viz., the representative of one firm making invidious remarks as to the capabilities of another firm in order to get his own more favourably noticed. It is a great pity that men in business cannot give and take. One firm cannot obtain all the orders, and must be prepared to see competitors now and again successful. According to the jury's finding, Mr. Scott, at Bradford, has been mulcted to the tune of £75, it being held that he made some disparaging remarks about the firm of Messrs. Andrews and Preece. It seems that both tendered for the same work, and, according to the evidence, when Mr. Scott was told that the work was not to be given to him he made the remarks complained about.

Change of Address.—Owing to the increase in their London business, Messrs. Walter T. Glover and Co. have removed from 10, Hatton-garden, to larger and more commodious offices at Albany-buildings, 39, Victoria-street, Westminster, where they hope for the continued support of their electrical friends. Considerable alterations and extensions having been made in their works and machinery at

Manchester, they are now prepared to give prompt delivery from stock of wires and cables for electrical purposes in vulcanised, pure indiarubber, and guttapercha insulations, silk and cotton covering, and their patent braiding, also armoured and lead-covered cables in all sizes, concentric cables, and their patent anti-induction and other telephone cables. Mr. Henry Edmunds desires us to call the attention of his friends to his change of address as above.

Anti-Magnetic Alloys.—M. Roussaille, president of the Syndical Chamber of Watchmakers of Lyons, in his paper upon "Watchmaking" at the Paris Exhibition, cites the following anti-magnetic alloys employed in the manufacture of watches: (1) "Mangor," an alloy of manganese and gold; (2) "Wolfor," composed of wolfram and gold; (3) "Woltine," formed by the union of platinum and gold; (4) "Cadmine," an alloy of which cadmium forms a large part—it is very hard and very elastic. To the alloys mentioned by M. Roussaille are added: (5) "Aror," composed of cadmium, gold, and manganese, and (6) "Manium," formed of manganese, platinum, bismuth, and copper. The anti-magnetic alloy best known in England—Hadfield's manganese steel, composed of a small percentage of manganese, added to ordinary steel—does not appear to have been mentioned.

Electric Light Fishing.—A fishing sloop left San Diego, recently, on a novel expedition, to last from one to three months. An electric plant has been put on board, and the fishing is to be done by the aid of incandescent lights and a net. Experiments in the bay proved that everything alive under the water is attracted by the glare of the light, and that thousands of fish of every description can be taken in a short time and with very little trouble. Four men were on board, and the boat has steered for the banks near San Clemente Island. The practical result of the first voyage will be watched with much interest, and if it is as successful in deep water as the experiments in the bay have been, the projectors of the enterprise are confident they will have solved the problem of supplying all Southern California with cheap fish. W. G. Riffenberg, a citizen of San Diego, is the inventor of the apparatus.

Helston.—At the last meeting of the Helston Town Town Council, Mr. J. E. Veale, of St. Austell, who has been consulted on the question of electric lighting, gave as his opinion that the proposed lighting is practicable, and that the disposition of the town lighting will adopt itself well to the electric light. Three plans are suggested for carrying out the work; the first is to utilise the water power available at Lower Town to transmit the electricity from thence to a centre near the market-house and distribute it through the various streets and buildings by about five miles of underground cables. The second plan is to use gas engines with gas obtained on the Dowson system, and the third is to use oil engines. The estimated cost of the plans is, respectively, £2,070, £1,724, and £1,590. The annual cost is estimated at: water power, £198. 10s.; gas, £192. 4s.; and oil, £185. 10s. Letters on the same subject were received from the Manchester Edison-Swan, and from Messrs. J. E. H. Gordon and Co.

Sims-Edison.—The following is from the *Times*: "There is to be a new application, of high importance, of the Sims-Edison invention for propelling and controlling torpedoes, which was exhibited in May last at Havre and described at length in the *Times*. The principle of control has been utilised in connection with lifeboats by the distinguished scientist Mr. Edison and the eminent engineer, his colleague. At present a boat, with sides necessarily low enough for rowing, is propelled through the surf by 10 to 12 men, who, at the risk of their lives, produce about 1 h.p. The idea in the minds of Mr. Edison and Mr. Sims has been to exchange this feeble force for the all but unlimited power of electricity. The boat they have designed could be sent through the surf for miles up and down the coast, if necessary, and out to a vessel in distress with a force of 32 h.p. Only two men are required to steer it, and the elaborate devices necessitated by the torpedo are not needed."

Taunton.—We regret that we cannot enter fully into a description of the electrical exhibition, but at present merely say that Field-Marshal Sir J. Lintorn Simmons on Saturday performed the opening ceremony. The exhibition (which is held at the Taunton Electric Lighting Company's central electric lighting depot) is not large, but it is comprehensive, and is intended to illustrate the various uses to which electrical power can be applied. For instance, an oil engine drives a Newton dynamo, which conveys the electric current to a large number of electric incandescent lamps of various artistic shapes. The same power also drives small motors attached to sewing machines, and also warms a patent lubricator, by means of which eggs are hatched by electricity, and works a churn. An electric launch has been placed on the Tone, in which short trips are taken up and down the river. At a luncheon at which Sir J. L. Simmons was entertained, the gallant Field-Marshal referred to the Sims-Edison torpedo as being an important step in naval warfare.

Edinburgh.—The Corporation of Edinburgh have now obtained the Royal assent to their electric lighting provisional order. In the Act confirming it, which is known as the Electric Lighting Orders Confirmation (No. 6) Act, 1891, Edinburgh and Paisley were bracketed together. At Tuesday's meeting of the Town Council, Mr. Auldjo Jamieson asked what was to be done with it. Since Tuesday, the committee which was in charge of the order while it was in Parliament sat to consider what they were to do, and came to the conclusion that in procuring the order they had exhausted their duties; and that they could only report the matter to the Council, and wait for further instructions. "This does not look," says the writer in the *Journal of Gas Lighting*, "as if there was much eagerness to take up electric lighting; and I believe this to be the fact. Had it not been to keep out speculative companies, the provisional order would never have been heard of. Mr. Jamieson's question must, however, be answered; and it will be interesting to watch how the Corporation set about the carrying out of the very unwelcome task which has been thrust upon them by the order."

Frankfort Exhibition.—The work of transmitting 300 h.p. at a distance of 120 miles upon the line Lauffen, Frankfort, which was begun about the middle of July, is progressing very favourably. On the line Frankfort-Jagsefeld, which is being built by the Imperial Government, eight gangs of workmen are busily engaged, whilst three gangs are working on the Wurtemberg side. The vast material necessary for the building of the line, consisting of specially constructed telegraph poles, cross-bars, and insulators, having arrived on the spot in good time, and aided by the practical and energetic measures of the employés engaged upon the work, nearly all the telegraph poles along the whole line are in their places, in spite of unusual difficulties connected with the mountainous nature of the soil having had to be surmounted. Thanks to the exertions of the firm of Hesse Söhne Heddernheim, who delivered the necessary quantity of above 1,200 miles of copper wire at the respective places within the space of a few days, the putting up of the wires will begin next week. Not less than 750 kilogrammes of oil will be

necessary to fill the insulators. There is now every reason to believe that the three wires of about 120 miles each will be fixed and in working order by the middle of August.

Canterbury.—At a meeting of the Canterbury Town Council on Tuesday, the town clerk read a letter from the Brush Electrical Engineering Company, saying that they were prepared to undertake the formation of a local company to take over the provisional order which the Corporation has obtained, and to refund the cost of the order, which they understood to be about £200, as soon as the necessary capital had been raised. Councillor Wells asked if the Brush Company were going to do it without any guarantee. The town clerk answered in the affirmative. Alderman Mount said he supposed if the Council accepted the offer it would be surrounded with safeguards in order to be on the safe side. The Mayor said at Dover they had advertised for tenders to take over the provisional order, but he did not know the result. Councillor Sanderson said he believed the tender of the Brush Company was accepted, and they were to form a company, and the Council would have the option of purchasing the undertaking at the end of 21 years. Alderman Mount said they had a better offer, with the option of buying at seven, 14, or 21 years. The Mayor proposed that their town clerk write to the town clerk of Dover asking him to send particulars of what had been done, and report at the next meeting, and this was agreed to by the members.

Lyons Electric Tramways.—The Lyons tramways seem to be run by a very enterprising company, and many experiments have recently been carried out to determine the most suitable method of mechanical traction. The fireless motors of the Frank and Lamm system, with superheated steam, were tried, then steam and petroleum engines, and, lastly, electric traction by means of cars carrying their own accumulators. The car is fitted with a motor by Alroth, of Basle, the current being supplied by 112 Faure-Sellon-Volckmar cells weighing 2¼ tons, the gearing being a Gall steel chain. The cells are placed under the seats and in two cupboards at the end, and the motor is placed beneath the car floor, so that nothing is seen but the switch handle alongside that of the brake. The total weight of the loaded car may be analysed thus (giving the weights in hundredweights): Car 104, motor 13½, switch and resistance 2, 40 passengers 53, battery 47; total about 11 tons. The accumulators can be connected in four different ways, corresponding with 50, 100, 100, and 200 volts for 80, 40, 20, and 20 amperes respectively. The various couplings are brought about by a set of brush contacts under the car, moved by a handle with dial and figures. At normal speed, 7½ miles an hour (12 kilometres) on the level, the current is used at 10 amperes, rising to 30 and 45 on gradients. The capacity of the battery is 150 ampere-hours, so that a minimum run of eight hours can be achieved without recharge. The lighting of the car is taken off the cells at 50 volts. So far the experiment appears to have been very successful, and M. Paplew, the managing director, seems strongly inclined to increase the number of electric cars on the Lyons tram lines.

Boat Race by Telephone.—Through the enterprise of the telephone company of New Haven, Connecticut, the stay-at-home people were able to follow the Yale-Harvard boat race from beginning to end. Three wires were stretched from the telephone building in New Haven, one of which was flagged off to represent the course, the miles being designated alternately by red and blue flags. From the other two wires were suspended miniature boats, the crew of one being painted blue to represent Yale and the other red for Harvard. As the race progressed and the telephone reports were received, these were drawn along the wires and the relative positions of the crews were shown, giving a very good idea of the contest. Five stations, equipped with a long-distance transmitter, were placed one at the start, and one opposite each of the mile flags. At the instant the word "go" was given by the referee it was telephoned to New Haven by the station at the start, and the miniature boats began their journey across the street, a cannon being fired from the top of the telephone building to call attention to the fact. By this time the street was blocked, and the crowd continually increasing. Meanwhile the Harvard boat was slowly creeping away from its rival in accordance with the reports received, and by the time the first mile flag was reached it was fully three lengths ahead; at the same time a large bulletin was displayed in the window, giving the time of both crews to that point, their strokes per minute, and the shape they were rowing in. When either of the crews spurted the sham boats gave evidence of the fact, and the crowd hardly breathed until the suspense was over. After the race was over the crowd quietly dispersed, all giving praise to the telephone company for representing the race. It is the sort of idea that might be taken up in Fleet-street and our own universities.

Frankfort Congress.—The International Electrical Congress will be held from September 7 to 12 at Frankfort. It is proposed to organise into sections, as was the case with former congresses, and to discuss the prominent electric topics of the day. Among the papers already promised are the following, together with their authors: Carhart: (1) "The Substitution of Dynamo Machines for Voltaic Batteries in Telegraphy"; (2) "Current Regulators for Dynamo Machine"; Dolbear: "Electrical Terminology"; Von Dolivo Dobrowolsky: "Electrical Transmission of Power by Alternating Currents"; Epstein: "Applicability of Electromagnetic Measuring Instruments—that is, those containing Iron, for Alternating Currents"; Feussner: "Material and Construction for Measuring Instruments"; Frölich: (1) "Objective Demonstration of Harmonic Curves, and Electro-Acoustic Experiments," (2) "Generation and Application of Ozone"; Holborn: "On the Magnetic Action of Different Iron Alloys;" Hummel: "Direct Determination of the Work of Magnetisation and the Currents in an Iron Ring"; Kahle: "The Permissible Limits of Error in Measuring Instruments, in Relation to Heat, Remanent Magnetism, etc."; Kareis: (1) "Prevention of Cross-Talk in Telephone Wires Strung on the Same Pole," (2) "Prevention of Disturbances in Telephone Circuits by Induction from Wires Carrying Heavy Currents," (3) "Improvements in the Conductivity of Telegraph Lines"; Kohlrausch: "What is the Best Course of Study for the Education of the Electrical Engineer?"; Löwenherz: "Introduction of Uniform Screws in Electrical Work and Instrument Making"; May: "Regulations for Electrical Conductors from the Standpoint of the Fire Insurance Companies"; Meissner: "Application of Lippmann's Capillary Electrometer to Cable Telegraphy;" Muller: "Arrangement of Storage Batteries for Light and for Heavy Work"; Peukert: "On Electric Meters"; Rothen: "Important Questions in the Domain of Telephony." Papers have also been promised by Dubois, Ferraris, Grawinkel, Quincke, Alioth, Arnold, Görges, Slaby, and others.

Marx Process of Storing Electric Energy.—Mention was made some months ago of a liquid "electroline," which comprised the active material of an accumulator or battery instead of the plates. Great expectations were formed of it, and we believe Mr. Kapp reported upon it, but nothing further has been lately heard of it. The following particulars from the *Elektrotechnischer Anzeiger*

will, however, be interesting: The apparatus in use hitherto for the storing of electric energy (accumulators) are based upon certain chemical reactions which occur only at the electrodes, so that with apparatus of this type the same electrodes are obliged to be used for both charge and discharge. This is not without its inconveniences, especially when the discharge is to take place at some other place than the charge. In the Marx process the electrical energy is stored, not at the electrodes, but in a liquid subjected, by means of a special charging apparatus by means of the electric current, to a determined chemical change. This liquid, charged, so to speak, by the electric current, has been termed "electroline." The electrodes of charge may be any conducting substance, such as carbon; the discharge electrodes may be of metal. An example will serve to make the process clearer. A glass vessel is filled with 450 grammes of chloride of iron, 900 grammes of water, and about 500 grammes of hydrochloric acid. After the salt is dissolved, two or three plates (in the latter case two positive and one negative) are placed within the bath without touching and correspondingly connected to the positive and negative poles of a dynamo. The passage of the current causes a decomposition of the liquid, which turns greenish, then yellow, and finally passes to a yellowish brown. When the liquid will not absorb further energy, the negative plates are removed and then the positive. While the present accumulators only return their charge with the same electrodes, the electroline requires a change of plates, one of metal and one of higher resistance, such as carbon. A plate of very porous carbon on one well pierced with holes is placed between two metal ones—zinc, copper, or iron. If now the circuit is completed an energetic current is given off, while the liquid decomposes, passing by the same series of colours in inverse order.

Cuba-Brazil Cables.—On the 31st ult. the engineer-in-charge, Mr. Theophilus Smith, telegraphed that the Cayenne-Viseo section of these cables was successfully laid. This completes the system of about 2,500 nautical miles which Mr. Sharpey Seaton, the acting partner (for this special purpose) of the Société Générale des Téléphones, undertook to lay for the Société Française des Télégraphes Sous-Marins under contracts made in July and August of last year. The programme of the first expedition was drawn up on the 17th September, 1890. It was to commence on the 15th October and to last 78 days, but subsequently 14 days' extra work were added to the programme, thus extending it to 92 days. The "Westmeath" passed Dover on the 17th October outward, and on the 17th January homeward bound (92 days). The programme of the second expedition was drawn up on 6th March, 1891. It was to commence about 20th April and to last 117 days. The "Westmeath" sailed on 22nd April, and completed her work on the 31st July (100 days). The voyage would occupy 17 or 18 days if the "Westmeath" came direct, but it has recently been decided to give the ship extra work in laying the spare cable between St. Pierre and Fort-de-France and elsewhere. The "Ludgate" was taken up for a minimum period of four months; she will be redelivered to her owners before its expiration. During these four months she has been fitted with cable tanks and gear, has laid 2,250 tons of cable between Surinam and Brazil, and she is now being dismantled for restoration to her owners. The first expedition was directed by Mr. Seaton in person; the second by Mr. Theophilus Smith, who is assisted by Messrs. Stallibrass, Page, Schischkar, Hall, Roussel, Fisher, Bevan, Sullivan, Spain, and other engineers and electricians, as well as by Captain Stonehouse and Mr. Dunn, the chief of the engine-room. The first message over the new cable was addressed to President Carnot by the Governor of Guayana and the President of the Council-General. Of the cables above mentioned, about 1,000 miles were manufactured by Messrs. Henley and Co., in London, the remainder by the Société Générale des Téléphones, at their newly-established works at Calais. There are altogether some nine or ten different types of cable, but the shore ends are principally about nine-ton, and the main cable about four-ton cables.

Bacup Town Council.—At the monthly meeting of this Council Mr. Heyworth (town clerk) read the following letter relating to the electric lighting of Bacup: "Royal Insurance-buildings, Newcastle-on-Tyne, July 7th, 1891. Dear Sir,—In reply to your esteemed favour of the 26th ult. *re* electric lighting, we beg to say we have carefully considered the matter, and would suggest an installation of 100 arc lamps as suitable for your town lighting. The cost of such an installation—consisting of engines, boilers, dynamos, a suitable engine house, 100 arc lamps each of 2,000 c.p. nominal, 100 iron lampposts, wooden poles to support overhead wires, insulated copper wire to fulfil Board of Trade requirements, and everything necessary to make a complete installation—would be about £9,000. The cost of working such an installation, if the authorities had it in their own hands and worked it themselves, would be as follows: Wages £4 per week, coal 4cwt. per hour, and carbons, etc., 2s. per hour, for the time all the lamps are burning. The light given by 100 arc lamps would be 100,000 c.p., whereas the light given by your present 632 gas lamps will, at best, not exceed 6,000 c.p. The annual rental, including purchase of plant, which we would charge for putting down, maintaining against all risks, and working the installation, under a guarantee to provide a constant and efficient light, would be about £25 per lamp per annum, plus the proportion of the cost agreed to be paid off annually, and 5 per cent. interest on the remainder. It would decidedly be to the advantage of the authorities for them to purchase the plant and work it themselves, and allow us to maintain it in good working order, at a very much reduced yearly charge. The current for incandescent lighting by private consumers could be generated at 2d. to 3d. per unit, which is equivalent to gas at from 1s. 2d. to 1s. 8d. per 1,000 cubic feet. The charge to private consumers in Newcastle is 6d. per unit, and in London 8d. per unit, so you will see that a fair profit could be derived from this source. Should your authorities think favourably of adopting the electric light we shall be glad to make a careful survey of the district, and give you a definite estimate, on payment of our representative's travelling expenses, and to give you any other information or advice in our power free of charge. Trusting the foregoing will be sufficient for your preliminary discussion, — We remain, yours obediently, Nicholson and Jennings. P.S. — Comparative cost of electric lighting and gas lighting:—British Museum: Electric light costs 6s. per hour, gas costs 15s. per hour; Albert Hall: Electric light costs £1. 10s. 6d. per night, gas costs £4. 7s. 6d. per night; South Kensington Museum: Electric light costs £1,224 per annum, gas costs £2,845 per annum. Thames Embankment: Electric light costs 5·66d. per 1,000 c.p. per hour, gas costs 1s. per 1,000 c.p. per hour. Dr. Cheadle, F.R.C.P., in a paper he recently read on 'The Progress of Hygiene,' says: 'The great injury inflicted by gas-polluted air is shown by the recent experience of the Great Western Railway Company. It is stated that since the electric light was introduced into their offices the percentage of absences from illness has fallen from 10 per cent. to 2 per cent. The introduction of the electric light will do much for the sanitation of houses, shops, and offices.'"

SIMS-EDISON TORPEDO.

From a note in another column it will be seen that the Sims-Edison electrical mechanism, as hitherto used for torpedoes, is to be applied to other boats, hence it may be as well to describe this mechanism a little more in detail. Fig. 1 represents diagrammatically the arrangement. It must be understood that the boat is regulated by an electric current generated at a fixed station, wires connecting the moving boat with the fixed station. Ordinarily at the station there is a steam engine of not less than 60 h.p., a dynamo, A, a key, B, an ammeter, a voltmeter, a battery, C, giving a current of 15 amperes at 20 volts, and a key, D. A cable connects the torpedo with the dynamo and battery. It consists of concentric conductors insulated from each other. The interior conductor has a section of 1·6 $mm.^2$ to carry the battery current. The external conductor has a section of 15 $mm.^2$ to carry the current of the dynamo. The whole is well insulated. The total diameter of the cable is 8·5 mm., and is tested under a current of 24,000 volts. One extremity is fixed at the station, the major portion of the cable at starting being rolled in a compartment of the torpedo, and is, of course, unrolled as required. This provides the means of guidance. It is unnecessary to enter into any detailed account of the torpedo itself, which is fairly well known. It contains several compartments, one of which is filled with the explosive material, which is supposed to contain about 250 kilogrammes of dynamite, or about 10 times the charge for the Whitehead torpedo—a sufficient charge to break up the most solidly constructed vessel at a distance of 50ft. The supplementary chamber, however, contains 400 kilogrammes of dynamite. The charge is fired by means of a detonator. A second compartment simply insulates the explosive charge from the rest of the torpedo. The third contains a cable wound in a hollow reel. It is so arranged as to permit the cable to be unrolled from the centre. The fourth compartment contains the propelling apparatus, and a supplementary arrangement for firing the charge. Here we find the series motor, Z, running at about 800 revolutions a minute, taking 28 amperes at 1,100 volts, giving 35 effective h.p. This motor actuates a screw. Besides rotating the screw, the motor also actuates a train of wheels shown at G H, Figs. 1 and 2, causing the projecting pieces shown at I to close the firing circuit. The firing apparatus is shown in M N P. The fifth chamber contains the governing apparatus shown in Fig. 4. It consists of two electromagnets, Q, placed symmetrically round the shaft of the screw. The armature, R, is connected through S to the rudder, T. Each of the electromagnets actuates a smaller armature, U, connected to a jointed lever, the extremity of which is connected through the terminal, v, to the terminal, W, whenever this extremity comes under the spring, x. The resistance, y, is interposed between the terminals, W, and f, and is equal to each of the magnets, Q. The governor is intended to vary the action of the rudder, and hence the direction of the torpedo. The rudder relay, or the relay governing the rudder, is shown in Fig. 3. It consists of an electromagnet, a, in the circuit of the battery, C, of a permanent magnet, B, and of two armatures, N N, which are prolonged in bronze pieces $d\ d^1$, Fig. 1. It is kept in ordinary position by springs $e\ e^1$, which are respectively connected with the terminals $f\ f^1$, and by these with the terminals, W W^1, of the apparatus governing the rudder. At the time of launching, the apparatus is as shown in the diagram, Fig. 1. The generating current comes by the terminal f to the motor, and can go to earth by three roads. First, by the resistance y, terminal W, lever U, wire g, armature d^1, terminal e^1, terminal f^1, motor, z, and to earth. The second road: terminal e, armature d, wire g, and then as by the first road. The third road is terminal e, electromagnet Q, wire g, and as before.

The diagram, Fig. 1, shows the method of propulsion, contact being made by the key B, so that the armature, P, of the firing relay is in contact with the left terminal, Fig. 1. The current goes principally by the second above-enumerated ways, which is that which offers the least resistance to the motor and without actuating the electromagnet, Q Q^1, acts upon the motor which puts in motion the screw of the torpedo, giving the torpedo a velocity of from 20 to 22 knots. This can be modified at the will of the operator, and the direction of the torpedo can be modified by actuating the relay and the rudder as previously described.

THE MIDGET ARC LAMP.

The great economy of arc as compared with incandescent lighting renders interesting any attempt to popularise the use of small arc lamps. For large shops or small lecture theatres something between the usual large arc and the ordinary incandescent lamp has long been wanted. It is absolutely necessary, not only that these small lamps should possess perfect steadiness, but also that they should be so simple in construction that they may be relied on for keeping in working order without constant skilled attention.

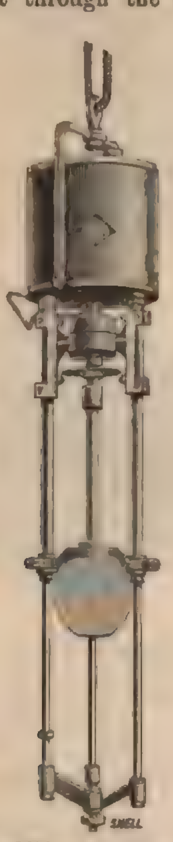
A lamp which fulfils these conditions is now being introduced by Messrs. Woodhouse and Rawson. It is called the "Midget," from its small size, and is made to give 250 c.p., using 5 amperes at an E.M.F. of 45 volts, so that even with this small size of lamp we obtain 1 c.p. of light for the expenditure of every "watt" of electrical energy used.

The illustration shows the general appearance of the lamp. The smallness of the globe prevents any depth of

shadow, and minimises any complaint which may be urged against the inequality of the distribution of the light.

The principle upon which the lamp works may almost be called simplicity itself. The upper part of the rods forming the frame of the lamp are hollow, and in these the lower portions slide quite easily. The bottom carbon is attached to the lower part of the frame, which is fastened to the upper portions of the lamp by a chain passing up the hollow pillar forming the upper portion of the lamp, round a pulley-wheel, whose motion is controlled by clockwork, and then to the upper carbon-holder, which acts as a counterpoise and slides freely between the hollow pillars forming the frame of the lamp.

The motion of the pulley is controlled by clockwork, which is started and stopped by a pivoted bar, on whose under surface a number of teeth are situated. These engage a pointer attached to the pendulum of the clock. This bar is pivoted in the centre, and attached each end to iron plungers which move inside the cores of electro-magnets actuated respectively by the main and shunt circuits. When, owing to the distance between the carbon points, the resistance of the main circuit increases, and consequently the current through the shunt increases, the



The Midget Arc Lamp.

plunger is drawn further into the core round which the shunt circuit passes and the pendulum is released; the clockwork moves the carbons nearer together until the main circuit increases so much as to draw the other plunger into the core round which it passes, and so overpowers the effect of the shunt circuit. The bar is drawn down, the teeth engage the pendulum of the clockwork, and the carbons are maintained apart until, owing to the burning away, the same action is repeated. This action is so delicate that no inconvenience at all is caused by the intermittent feed—indeed, it is scarcely noticed.

When the current is stopped the pendulum is released, owing to the action of a spring upon the bar, and the clockwork causes the carbons to remain together.

In the small box over the upper carbon-holder, the current, before passing to the carbon, magnetises an iron core, and lifts the upper carbon a small distance above the lower one, and thus forming the arc when the current is first put on the lamp. The carbon is held up in this manner all the time the current is passing through the lamp. The lamp in wound in three different ways—one suitable for parallel working, one for series, and one for use with alternating currents.

ELECTRIC LIGHT ON SHIPBOARD.*

SYSTEMS OF WIRING.

Electric light being now an absolute necessity on a large proportion of the mercantile as well as the fighting navies of the world, and a knowledge of the requirements connected with its use having hitherto been almost entirely confined to the specialists by whom it is installed, we have thought that shipowners would be glad of a short statement, given as far as possible in non-technical language, of the methods adopted for the wiring of their boats, and the precautions necessary to guard against the occurrence of fires. As a preliminary to this statement, however, it will be well to point out the place occupied by the wiring in regard to the whole installation. A system of electric lighting is not analogous to a system of gas lighting. In the latter case, the current of gas has to be conveyed from the source of supply to the illuminating flame, after leaving which, in a changed condition, it is generally left to poison the atmosphere and shift for itself. The electric current, on the other hand, is unchanged in both volume and nature after passing through the lamp, and has to be led back to the dynamo, to be, as it were, again put under pressure for further use. The electric circuit may, as a popular exposition of the subject, be likened to the flow of water round and round in an endless pipe. At one point the pipe is enlarged to receive a pump, and at other points is obstructed, say, by pieces of sponge or porous stone, to force the full body of water, through which great pressure has to be exerted by the pump. In the electric analogue the pump is represented by the dynamo, the pipe by an insulated metal conductor, and the obstructing sponges by the lamps. Certain practical considerations prevent the placing of the lamps all in a row, one after the other, or, as it is termed, "in series," on one circuit, or even on a considerable number of circuits. The arrangement of each circuit is as if two large water mains were carried along the ship, side by side, and connected to the pump, so that water is drawn from one main and delivered into the other. Instead of having their further ends joined together, so as to form one endless pipe, as in our previous supposition, the two mains are connected at intervals, as required, by branch pipes containing sponges. In each of these branch-connecting pipes a tap may be inserted for the purpose of turning the water on or off as required. With this arrangement the pump has to maintain a constant difference of pressure between the two mains, and each sponge passes the proper amount of water, however many or few are in action at once. A sponge in a water-pipe may not at first seem a good simile for a bright light, but on consideration it will be found not inapt. The incandescent or glow lamp (the lamp universally used on board ship, except for special purposes, such as powerful search-lights) owes its brightness to what may be called friction between the electric current and the thin thread of carbon, known as the "filament," along which it has to travel. In this case the conductor is so small and the current so comparatively large that the friction makes the conductor white hot. The light then is merely an incidental effect due to a thin strip of carbon being heated. Now, though the sponge in the water-pipe does not become white hot and give light, the difference in effect is only in degree; the sponges, water, and pipes do become warmed in proportion to the work done in forcing the water through its circuit, just as the lamp filament and conducting mains become warmed in proportion to the work done in forcing the electric current through them. In the former case a large mass of matter is heated to a small extent, while in the latter the effect is concentrated on a very small mass of matter, which, therefore, is intensely heated. The conducting wires may, we see now, be for practical purposes considered as acting the part of pipes, and the lamps as obstructions in them; for, more correctly, the indiarubber or other insulation surrounding the wire acts the part of the metal in the pipe, and the conductor in the centre acts as the hollow space inside the pipe. The nature of electric currents—if currents they really are—and why they can pass through a dense metal like copper six times as easily as through iron, or nine thousand million million

* From the *Liverpool Journal of Commerce*.

million times as easily as through indiarubber, are unsolved mysteries. The practical outcome of the foregoing considerations is that three methods of wiring on shipboard have been worked out. These are known respectively as "single," "double," and "concentric" wiring. In single wiring the hull of the ship forms the return conductor from the lamps to the dynamo; a conductor being led from every lamp to the ironwork of the hull. In double wiring the current is not allowed to enter the hull of the ship at all, but returns to the dynamo through an insulated main, being in all respects analogous to the hydraulic system sketched above. Concentric wiring is also a double wiring, but one conductor is throughout enclosed in the other, with the insulating indiarubber in between. With any of these systems good results so far as regards the lighting of the boat may be obtained. We would, however, most strongly urge that whatever system may be adopted, the work and materials must be of the highest class if a thoroughly good and lasting installation is to be had. If the work is well designed and carried out, little or no trouble should be experienced for years; whereas, if the materials are flimsy, or the workmanship hurried, continual cutting out and patching up will be required almost from the first, to say nothing of fire risks. The simple acceptance of the lowest tender for an installation, without some guarantee of high-class work, is very bad economy indeed. For some time now the single-wire system has been used very extensively, and it would probably have continued in favour but for the fact that Sir William Thomson has delivered its death-blow on account of its influence on compasses, as will be seen from the following extract from the *Electrical Review* of May 8 last: "In his lecture on 'Electric and Magnetic Screening,' at the Royal Institution, Sir William Thomson condemned the use of the 'single-wire' system of lighting ships by electricity on the ground that observation has shown it to produce an error in the ship's compass of 3deg. to 7deg., every care being taken . . . . the complete two-conductor system." Commenting on the last sentence of the above, Sir William Thomson, in the *Electrical Review* of another date, says: "We see, then, that on account of the compasses it is necessary that the dynamos shall not be capable of causing currents to flow through the hull of the ship at any considerable distance beyond the dynamo-room." The advantages pertaining to double wiring are that compasses are unaffected, and that a double thickness of insulation intervenes between the wires to prevent leakage or short circuits. The disadvantages are that there are two conductors to be provided and separately insulated and protected. The installation of the electric light on shipboard involves the overcoming of far greater difficulties than are met with under ordinary circumstances on shore; the great changes of temperature, the constant straining and vibration, the salt sea air, and the ever-present and insidious moisture—that great enemy of insulation—together form a vigilant body of foemen, ever ready to defeat the efforts of the electrician, if only he can be caught sleeping. How, then, are these special dangers to be best guarded against? In the first place, the insulation on the wires must be of a high class, and thoroughly protected from mechanical injury; then means should as far as possible be provided for preventing any strain from coming on the copper conductor inside, more particularly at the joints. Copper used for electric light leads is of a hard, springy nature, and far more easily broken by bending than the soft copper wire with which everyone is familiar. Joints should be as few in number as practicable, and great care must be exercised in making good where the insulating material has been cut away for the purpose of jointing, and in vulcanising the freshly applied indiarubber. Cut-outs must be introduced wherever a reduction in size of wire occurs. It is a good rule to have no wire smaller than No. 15 standard wire gauge (or a stranded conductor of No. 22 is better), and cut-outs are then required in the proportion of one to about every 12 lights. The connections with lamp fittings, switches, and cut-outs require special attention. These are generally made (the smaller sizes in particular) by clamping the bare ends of the conductors under the heads of ridiculously little *binding screws, which are left free to* shake loose or not, as fate may determine. Considering the large number of these connections, it is a pity that some more substantial and quickly-manipulated coupling is not used.

[We imagine that the coupling as described and illustrated in our description of the lighting of the "Scot" is just the one required.—Ed. *E.E.*]

EXPERIMENTS WITH ALTERNATE CURRENTS OF VERY HIGH FREQUENCY AND THEIR APPLICATION TO METHODS OF ARTIFICIAL ILLUMINATION.*

BY NIKOLA TESLA.

(Continued from page 113.)

By preventing completely the exchange of the air molecules, the local heating effect may be so exalted as to bring a body to incandescence. Thus, for instance, if a small button, or preferably a very thin wire or filament, be enclosed in an unexhausted globe and connected with the terminal of the coil, it may be rendered incandescent. The phenomenon is made much more interesting by the rapid spinning round in a circle of the top of the filament, thus presenting the appearance of a luminous funnel, Fig. 16, which widens when the potential is increased. When the potential is small the end of the filament may perform irregular motions, suddenly changing from one to the other, or it may describe an ellipse; but when the potential is very high it always spins in a circle; and so does generally

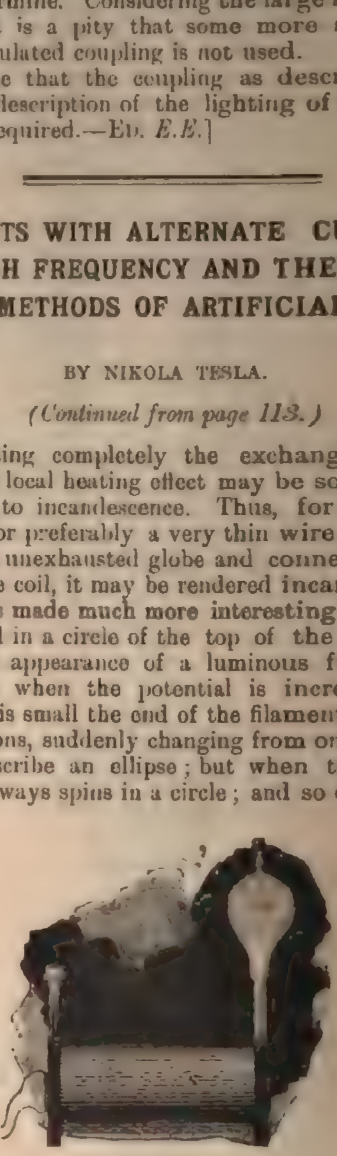


Fig. 16.

a thin straight wire attached freely to the terminal of the coil. These motions are, of course, due to the impact of the molecules, and the irregularity in the distribution of the potential, owing to the roughness and dissymmetry of the wire or filament. With a perfectly symmetrical and polished wire such motions would probably not occur. That the motion is not likely to be due to other causes is evident from the fact that it is not of a definite direction, and that in a very highly-exhausted globe it ceases altogether. The possibility of bringing a body to incandescence in an unexhausted globe, or even when not at all enclosed, would seem to afford a possible way of obtaining light effects which, in perfecting methods of producing rapidly alternating potentials, might be rendered available for useful purposes.

In employing a commercial coil, the production of very powerful brush effects is attended with considerable difficulties, for when these high frequencies and enormous potentials are used, the best insulation is apt to give way. Usually the coil is insulated well enough to stand the strain from convolution to convolution, since two double silk covered paraffined wires will withstand a pressure of several thousand volts; the difficulty lies principally in preventing the breaking through from the secondary to the primary, which is greatly facilitated by the streams issuing from the latter. In the coil, of course, the strain is greatest from section to section, but usually in a larger coil there are so many sections that the danger of a sudden giving way is not very great. No difficulty will generally be encountered in that direction, and, besides, the liability of injuring the coil internally is very much reduced by the

* Lecture delivered before the American Institute of Electrical Engineers at Columbia College, New York, May 20.

fact that the effect most likely to be produced is simply a gradual heating, which, when far enough advanced, could not fail to be observed. The principal necessity is then to prevent the streams between the primary and the tube, not only on account of the heating and possible injury, but also because the streams may diminish very considerably the potential difference available at the terminals. A few hints as to how this may be accomplished will probably be found useful in most of these experiments with the ordinary induction coil.

One of the ways is to wind a short primary, Fig. 17A, so that the difference of potential is not at that length great enough to cause the breaking forth of the streams through the insulating tube. The length of the primary should be determined by experiment. Both the ends of the coil should be brought out on one end through a plug of insulating material fitting in the tube as illustrated. In such a disposition one terminal of the secondary is attached to a body the surface of which is determined with the greatest care so as to produce the greatest rise in the potential. At the other terminal a powerful brush appears, which may be experimented upon.

The above plan necessitates the employment of a primary of comparatively small size, and it is apt to heat when powerful effects are desirable for a certain length of time. In such a case it is better to employ a larger coil, Fig. 17B, and introduce it from one side of the tube, until the streams begin to appear. In this case the nearest terminal of the secondary may be connected to the primary or to the ground, which is practically the same thing, if the primary is connected directly to the machine. In the case of ground connections it is well to determine experimentally the frequency which is best suited under the conditions of the test. Another way of obviating the streams, more or less, is to make the primary in sections and supply it from separate well-insulated sources.

FIG. 17A.

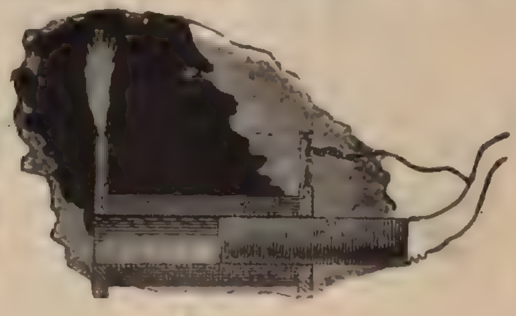

FIG. 17B

In many of these experiments, when powerful effects are wanted for a short time, it is advantageous to use iron cores with the primaries. In such case a very large primary coil may be wound and placed side by side with the secondary, and, the nearest terminal of the latter being connected to the primary, a laminated iron core is introduced through the primary into the secondary as far as the streams will permit. Under these conditions an excessively powerful brush, several inches long, which may be appropriately called "St. Elmo's hot fire," may be caused to appear at the other terminal of the secondary, producing striking effects. It is a most powerful ozoniser, so powerful, indeed, that only a few minutes are sufficient to fill the whole room with the smell of ozone, and it undoubtedly possesses the quality of exciting chemical affinities.

For the production of ozone, alternating currents of very high frequency are eminently suited, not only on account of the advantages they offer in the way of conversion but also because of the fact of the ozonising action of a discharge is dependent on the frequency as well as on the potential, this being undoubtedly confirmed by observation.

In these experiments if an iron core is used it should be carefully watched, as it is apt to get excessively hot in an incredibly short time. To give an idea of the rapidity of the heating, I will state that by passing a powerful current through a coil with many turns, the inserting within the same of a thin iron wire for no more than one second's time is sufficient to heat the wire to something like 100deg. C.

But this rapid heating does not need to discourage us in the use of iron cores in connection with rapidly alternating currents. I have for a long time been convinced that in the industrial distribution by means of transformers, some such plan as the following might be practicable. We may use a comparatively small iron core, subdivided, or perhaps not even subdivided. We may surround this core with a considerable thickness of material which is fireproof and conducts the heat poorly, and on top of that we may place the primary and secondary windings. By using either higher frequencies or greater magnetising forces, we may by hysteresis and eddy currents heat the iron core so far as to bring it nearly to its maximum permeability, which, as Hopkinson has shown, may be as much as 16 times greater than that at ordinary temperatures. If the iron core were perfectly enclosed it would not be deteriorated by the heat, and, if the enclosure of fireproof material would be sufficiently thick, only a limited amount of energy could be radiated in spite of the high temperature. Transformers have been constructed by me on that plan, but for lack of time no thorough tests have as yet been made.

Another way of adapting the iron core to rapid alternations, or, generally speaking, reducing the frictional losses, is to produce by continuous magnetisation a flow of something like 7,000 or 8,000 lines per square centimetre through the core, and then work with weak magnetising forces and preferably high frequencies around the point of greatest permeability. A higher efficiency of conversion and greater output are obtainable in this manner. I have also employed this principle in connection with machines in which there is no reversal of polarity. In these types of machines, as long as there are only few pole projections, there is no great gain, as the maxima and minima of magnetisation are far from the point of maximum permeability; but when the number of the pole projections is very great, the required rate of change may be obtained, without the magnetisation varying so far as to depart greatly from the point of maximum permeability, and the gain is considerable.

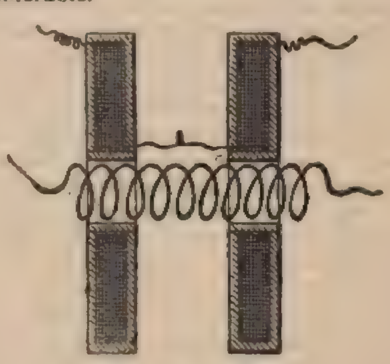

FIG. 18.

The above described arrangements refer only to the use of commercial coils as ordinarily constructed. If it is desired to construct a coil for the express purpose of performing with it such experiments as I have described, or, generally, rendering it capable of withstanding the greatest possible difference of potential, then a construction as indicated in Fig 18 will be found of advantage. The coil in this case is formed of two independent parts which are wound oppositely, the connection between both being made near the primary. The potential in the middle being zero,

there is not much tendency to jump to the primary, and not much insulation is required. In some cases the middle point may, however, be connected to the primary or to the ground. In such a coil the places of greatest difference of potential are far apart and the coil is capable of withstanding an enormous strain. The two parts may be movable so as to allow a slight adjustment of the capacity effect.

As to the manner of insulating the coil, it will be found convenient to proceed in the following way: First, the wire should be boiled in paraffin, until all the air is out; then the coil is wound by running the wire through melted paraffin, merely for the purpose of fixing the wire. The coil is then taken off from the spool, immersed in a cylindrical vessel filled with pure melted wax, and boiled for a long time until the bubbles cease to appear. The whole is then left to cool down thoroughly, and then the mass is taken out of the vessel and turned up in a lathe. A coil made in this manner and with care is capable of withstanding enormous potential differences.

It may be found convenient to immerse the coil in paraffin oil or some other kind of oil; it is a most effective way of insulating, principally on account of the perfect exclusion of air, but it may be found that, after all, a vessel filled with oil is not a very convenient thing to handle in a laboratory. If an ordinary coil can be dismounted, the primary may be taken out of the tube and the latter plugged up on one end, filled with oil, and the primary reinserted. This affords an excellent insulation, and prevents the formation of the streams.

Of all the experiments which may be performed with rapidly alternating currents, the most interesting are those which concern the production of a practical illuminant. It cannot be denied that the present methods, though they were brilliant advances, are very wasteful. Some better methods must be invented, some more perfect apparatus devised. Modern research has opened new possibilities for the production of an efficient source of light, and the attention of all has been turned in the direction indicated by able pioneers. Many have been carried away by the enthusiasm and passion to discover, but in their zeal to reach results, many have been misled. Starting with the idea of producing electromagnetic waves, they turned their attention, perhaps, too much to the study of electromagnetic effects, and neglected the study of electrostatic phenomena. Naturally, nearly every investigator availed himself of an apparatus similar to that used in earlier experiments. But in those forms of apparatus, while the electromagnetic inductive effects are enormous, the electrostatic effects are excessively small.

In the Hertz experiments, for instance, a high-tension induction coil is short-circuited by an arc, the resistance of which is very small, the smaller the more capacity is attached to the terminals; and the difference of potential at these is enormously diminished. On the other hand, when the discharge is not passing between the terminals, the static effects may be considerable, but only qualitatively so, not quantitatively, since their rise and fall is very sudden, and since their frequency is small. In neither case, therefore, are powerful electrostatic effects perceivable. Similar conditions exist when, as in some interesting experiments of Dr. Lodge, Leyden jars are discharged disruptively. It has been thought—and I believe asserted—that in such cases most of the energy is radiated into space. In the light of the experiments which I have described above, it will now not be thought so. I feel safe in asserting that in such cases most of the energy is partly taken up and converted into heat in the arc of the discharge and in the conducting and insulating material of the jar, some energy being, of course, given off by electrification of the air; but the amount of the directly radiated energy is very small.

When a high-tension induction coil, operated by currents alternating only 20,000 times a second, has its terminals closed through even a very small jar, practically all the energy passes through the dielectric of the jar, which is heated, and the electrostatic effects manifest themselves outwardly only to a very weak degree. Now the external circuit of a Leyden jar—that is, the arc and the connections of the coatings—may be looked upon as a circuit generating alternating currents of excessively high frequency and *fairly high potential*, which is closed through the coatings and the dielectric between them, and from the above it is evident that the external electrostatic effects must be very small, even if a recoil circuit be used. These conditions make it appear that with the apparatus usually at hand the observation of powerful electrostatic effects was impossible, and what experience has been gained in that direction is only due to the great ability of the investigators.

But powerful electrostatic effects are a *sine qua non* of light production on the lines indicated by theory. Electromagnetic effects are primarily unavailable, for the reason that to produce the required effects we would have to pass current impulses through a conductor which, long before the required frequency of the impulses could be reached, would cease to transmit them. On the other hand, electromagnetic waves many times longer than those of light, and producible by sudden discharges of a condenser, could not be utilised, it would seem, except we avail ourselves of their effect upon conductors as in the present methods, which are wasteful. We could not affect by means of such waves the static molecular or atomic charges of a gas, cause them to vibrate and to emit light. Long transverse waves cannot, apparently, produce such effects, since excessively small electromagnetic disturbances may pass readily through miles of air. Such dark waves, unless they are of the length of true light waves, cannot, it would seem, excite luminous radiation in a Geissler tube, and the luminous effects which are producible by induction in a tube devoid of electrodes, I am inclined to consider as being of an electrostatic nature.

To produce such luminous effects, straight electrostatic thrusts are required; these, whatever be their frequency, may disturb the molecular charges and produce light. Since current impulses of the required frequency cannot pass through a conductor of measurable dimensions, we must work with a gas, and then the production of powerful electrostatic effects becomes an imperative necessity.

It has occurred to me, however, that electrostatic effects are in many ways available for the production of light. For instance, we may place a body of some refractory material in a closed, and preferably more or less exhausted, globe, connect it to a source of high, rapidly alternating, potential causing the molecules of the gas to strike it many times a second at enormous speeds, and in this manner, with trillions of invisible hammers, pound it until it gets incandescent; or we may place a body in a very highly-exhausted globe, in a non-striking vacuum, and by employing very high frequencies and potentials transfer sufficient energy from it to other bodies in the vicinity, or in general to the surroundings, to maintain it at any degree of incandescence, or we may, by means of such rapidly alternating high potentials, disturb the ether carried by the molecules of a gas or their static charges, causing them to vibrate and to emit light. But, electrostatic effects being dependent upon the potential and frequency, to produce the most powerful action it is desirable to increase both as far as practicable. It may be possible to obtain quite fair results by keeping either of these factors small, provided the other is sufficiently great; but we are limited in both directions. My experience demonstrates that we cannot go below a certain frequency, for, first, the potential then becomes so great that it is dangerous; and, secondly, the light production is less efficient.

I have found that, by using the ordinary low frequencies, the physiological effect of the current required to maintain at a certain degree of brightness a tube 4ft. long, provided at the ends with outside and inside condenser coatings, is so powerful that, I think, it might produce serious injury to those not accustomed to such shocks; whereas, with 20,000 alternations per second, the tube may be maintained at the same degree of brightness without any effect being felt. This is due principally to the fact that a much smaller potential is required to produce the same light effect, and also to the higher efficiency in the light production. It is evident that the efficiency in such cases is the greater, the higher the frequency, for the quicker the process of charging and discharging the molecules, the less energy will be lost in the form of dark radiation. But, unfortunately, we cannot go beyond a certain frequency on account of the difficulty of producing and conveying the effects.

I have stated above that a body enclosed in an unexhausted bulb may be intensely heated by simply connecting

it with a source of rapidly alternating potential. The heating in such a case is, in all probability, due mostly to the bombardment of the molecules of the gas contained in the bulb. When the bulb is exhausted the heating of the body is much more rapid, and there is no difficulty whatever in bringing a wire or filament to any degree of incandescence by simply connecting it to one terminal of a coil of the proper dimensions. Thus, if the well-known apparatus of Prof. Crookes, consisting of a bent platinum wire with vanes mounted over it, Fig. 19, be connected to one terminal of the coil—either one or both ends of the platinum wire being connected—the wire is rendered almost instantly incandescent, and the mica vanes are rotated as though a current from a battery were used. A thin carbon filament, or preferably a button of some refractory material, Fig. 20, even if it be a comparatively poor conductor, enclosed in an exhausted globe, may be rendered highly incandescent; and in this manner a simple lamp capable of giving any desired candle-power is provided.

The success of lamps of this kind would depend largely on the selection of the light-giving bodies contained within the bulb. Since, under the conditions described, refractory bodies—which are very poor conductors and capable of withstanding for a long time excessively high degrees of temperature—may be used, such illuminating devices may be rendered successful.

It might be thought at first that if the bulb containing the filament or button of refractory material, be perfectly well exhausted—that is, as far as it can be done by the use of the best apparatus—the heating would be much less intense, and that in a perfect vacuum it could not occur at all. This is not confirmed by my experience; quite the contrary, the better the vacuum the more easily the bodies are brought to incandescence. This result is interesting for many reasons.

FIG. 19.

FIG. 20.

At the outset of this work, the idea presented itself to me whether two bodies of refractory material enclosed in a bulb exhausted to such a degree that the discharge of a large induction coil, operated in the usual manner, cannot pass through, could be rendered incandescent by mere condenser action. Obviously, to reach this result, enormous potential differences and very high frequencies are required, as is evident from a simple calculation.

But such a lamp would possess a vast advantage over an ordinary incandescent lamp in regard to efficiency. It is well known that the efficiency of a lamp is to some extent a function of the degree of incandescence, and that, could we but work a filament at many times higher degrees of incandescence, the efficiency would be much greater. In an ordinary lamp this is impracticable on account of the destruction of the filament, and it has been determined by experience how far it is advisable to push the incandescence. It is impossible to tell how much higher efficiency could be obtained if the filament could withstand indefinitely, as the investigation to this end obviously cannot be carried beyond a certain stage; but there are reasons for believing that it would be very considerably higher. An improvement might be made in the ordinary lamp by employing a short and thick carbon; but then the leading-in wires would have to be thick, and, besides, there are many other considerations which render such a modification entirely impracticable. But in a lamp as above described the leading-in wires may be very small, the incandescent refractory material may be in the shape of blocks offering a very small radiating surface, so that less energy would be required to keep them at the desired incandescence; and, in addition to this, the refractory material need not be carbon, but may be manufactured from mixtures of oxides, for instance, with carbon or other material, or may be selected from bodies which are practically non-conductors, and capable of withstanding enormous degrees of temperature.

All this would point to the possibility of obtaining a much higher efficiency with such a lamp than is obtainable in ordinary lamps. In my experience it has been demonstrated that the blocks are brought to high degrees of incandescence with much lower potentials than those determined by calculation, and the blocks may be set at greater distances from each other. We may freely assume, and it is probable, that the molecular bombardment is an important element in the heating, even if the globe be exhausted with the utmost care as I have done; for although the number of the molecules is, comparatively speaking, insignificant, yet on account of the mean free path being very great, there are fewer collisions, and the molecules may reach much higher speeds, so that the heating effect due to this cause may be considerable, as in the Crookes experiments with radiant matter.

But it is likewise possible that we have to deal here with an increased facility of losing the charge in very high vacuum, when the potential is rapidly alternating, in which case most of the heating would be directly due to the

FIG. 21.

FIG. 22.

surging of the charges in the heated bodies. Or else the observed fact may be largely attributable to the effect of the points which I have mentioned above, in consequence of which the blocks or filaments contained in the vacuum are equivalent to condensers of many times greater surface than that calculated from their geometrical dimensions. Scientific men still differ in opinion as to whether a charge should, or should not, be lost in a perfect vacuum, or, in other words, whether ether is, or is not, a conductor. If the former were the case, then a thin filament enclosed in a perfectly exhausted globe, and connected to a source of enormous, steady potential, would be brought to incandescence.

Various forms of lamps on the above-described principle, with the refractory bodies in the form of filaments, Fig. 21, or blocks, Fig. 22, have been constructed and operated by me, and investigations are being carried on in this line. There is no difficulty in reaching such high degrees of incandescence that ordinary carbon is to all appearance melted and volatilised. If the vacuum could be made absolutely perfect, such a lamp, although inoperative with apparatus ordinarily used, would, if operated with currents of the required character, afford an illuminant which would never be destroyed, and which would be far more efficient than an ordinary incandescent lamp. This perfection can, of course, never be reached, and a very slow destruction and gradual diminution of the size always occurs, as in incandescent lamps; but there is no possibility of a sudden and premature disabling which occurs in the latter by the breaking of the filament, especially when the incandescent bodies are in the shape of blocks.

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

PREVENTION BETTER THAN CURE.

The recent railway accident at Paris, in which one train telescoped another, and in which more persons probably were indirectly killed or injured than directly, has brought about a suggestion worthy of careful consideration by our railway authorities. In the accident referred to, the carriages were set on fire either by the coal from the engine fire, by the gas used for lighting, or by both. The danger from the coal of the engine is more remote in accidents of the kind than the danger from the gas. It has been pointed out that if trains were generally lighted by electricity, the chance of carriages catching fire in an accident would be very small. Certainly there would be less danger with electricity than with gas; but railway managers are only slowly realising the old axiom that prevention is better than cure. The railway era commenced with open trucks for passengers, with carriages built upon the plans of the old stage coach—stuffy and uncomfortable. Gradually the passengers were sheltered, and more and more care was taken with signalling apparatus—each move in advance in the latter direction being for the purpose of preventing accidents. The partial block gave way to the absolute block; interlocking points and signals, the abolition of facing points, were one and all moves in the direction of prevention. While improvement was being made in the permanent way, improvement was also going on in regard to the comfort of passengers. The strain upon the physical man during a journey to Antwerp by the Great Eastern Railway, to Edinburgh by the Great Northern, to Leeds by the Midland, to Holyhead by the London and North-Western, to Bristol by the Great Western, is hardly more, if it be as much, than the strain from any suburban retreat requiring three quarters of an hour's journey to the City. Prevention of accident, prevention of discomfort during long journeys, have been constantly moving views with the managers of most of our railway systems. The one weak link seems to have been suburban traffic, and this, especially on the southern lines, is a disgrace to civilisation. It may be asked, however, whether the greatest inducement in the eyes of the managers to improve permanent way and rolling-stock has not been that such improvement pays. The first and ruling passion of a manager is to make his line pay. The suggestion to light railway carriages with electrical apparatus is one we heartily support, in that we imagine it would be an improvement appreciated by the travelling public, would conduce to greater safety and comfort, and, above all, would pay. The *Lancet* has quite recently added its quota of evidence to the view that electricity in workshops and warehouses is healthy; we should like to have its opinion as to the evil effects of train lighting upon the eyes of constant travellers. It is absurd to preach a doctrine of do not read in a train. Business men must read, and travellers on pleasure bent will read. The best method to counteract the evil effect

of such reading is to provide plenty of light. Better a superabundance than a lack. It is, then, not so much on account of the less danger when an accident occurs that we advocate the use of electric train-lighting, because we believe the great object is primarily to prevent the accident; but we would have such lighting become general in order to prevent the evils arising from the present system, which consists simply in making darkness visible. What is there to prevent electrical train lighting? It is by no means a difficult problem, and we doubt if it is a more costly one than some of the systems at present in use of lighting by gas.

TRAMWAYS.

It may be remembered that exact figures as to the electrical working of tramways was in a measure promised by the chairman of the Birmingham Central Tramways. This promise has been fulfilled in the tables appended to the report of the directors, given elsewhere. Even these figures are delusive, and the electrical work does not show as well as it will in the future. Difficulties were encountered and had to be overcome, which increases the cost, but it is satisfactory to learn from the report that the profit earned is steadily improving. Care must be taken not to make invidious comparisons between tram lines. It cannot be taken that because a line at one place is satisfactorily worked, a similar line at another place would show similar results. The amount of possible traffic varies in different localities. However, the important point to decide is to find the minimum cost of working under given conditions. The tables referred to analyse the expenses showing the cost per mile run. The totals show cost per mile with steam to be 10·99d.; with horses, 9·79d.; with cables, 6·33d.; and with electricity, 9·90d. Here cable traction shows best, that of electricity and horses being almost the same, while steam is the most costly.

CORRESPONDENCE.

Justice needs that both be heard."

TOWNLEY'S DUPLEX ALARM.

SIR,—In answer to Mr. Townley's letter of to-day's issue *re* his duplex alarm, I have taken his advice and again taken the trouble to read carefully the description of his alarm given in your paper, and fail to see where the freedom from switches and complicated parts comes in.

If Mr. Townley will now do me the favour to also carefully read both his articles and my own, he will see that his arrangement comprises a bell with five moving parts. In mine there is one. His contacts, P and P^1, are liable to oxidise. With mercury cups bad contact is impossible. He trusts to plain contact in clock. In mine there is a *switch*, with a knife edge lever, which drops into a split pillar, actuated by a spiral spring with a rotary pressure of 2lb.; thus securing a powerful rubbing contact.

He has had his clock and alarm in use for 12 months; I have had mine in use full five years, therefore = five recommendations.

In conclusion, I still fail to see the novelty attached to Townley's duplex alarm.—Yours, etc.,

Norwood, S.E., July 31, 1891. A. MCMEEKIN.

EDISON DYNAMO AND MOTOR.*

It is one thing to make a dynamo or motor from explicit instructions and quite another thing to design a machine adapted to generate or be operated by a particular current. The former is purely mechanical and within the range of most machinists and amateurs, while the latter is entirely within the province of the electrical engineer or electrician. When the work of machine building proceeds simultaneously with the study of fundamental principles, real progress is made. For the benefit of those who proceed in this way, and in answer to many enquirers, we give a detailed description of an Edison ·25-kilowatt machine, designed for use as a dynamo for supplying a current for five Edison standard lamps, or for use on the Edison circuit as a $\frac{1}{4}$-h.p. motor.

Before beginning the description of the machine, it is but fair to say that it is thoroughly well made in every particular. The insulation in every part is very perfect, and the whole is so well made that any single machine built by a mechanic or amateur could but suffer by comparison with it; and, furthermore, we doubt if any maker of a single machine could even purchase the materials required for the price asked for the machine by the regular manufacturers. Therefore, if the machine is wanted, we advise a purchase. If experience is wanted, the making of the machine comes first in order, with a probable purchase to follow.

The engravings are one-sixth the actual size, linear measurement.

The base, which is of brass, is made hollow, as shown. It is 14in. long, $7\frac{3}{8}$in. wide, $1\frac{3}{4}$in. deep at the ends, with two $1\frac{1}{8}$in. elevations at the middle for receiving the cast-iron pole-pieces of the field magnet, which are each secured to the base by two small tap bolts extending upwardly through the base and into the pole-pieces.

The upper surfaces of the pole-pieces are truly faced for receiving the cylindrical field magnet cores, which are made of Swedish iron $2\frac{5}{8}$in. in diameter and $4\frac{1}{2}$in. long. These magnet cores are each held in position by a threaded stud screwed into the pole-piece and entering magnet core. Each core is provided with a vulcanised fibre collar at each end, which is $\frac{1}{2}$in. thick and $\frac{7}{8}$in. wide. Upon each core, and between the fibre collars, is wound $5\frac{1}{4}$lb. of No. 24 silk-covered copper wire, with a wrapping of thin varnished paper between the layers. The cores, before winding, are thoroughly insulated with the same material. The fibre collars are each held in place by three conical-headed screws entering the end of the core, with their heads projecting beyond the body of the core. To the inner and outer ends of the winding of each arm of the magnet are attached pieces of larger wire to avoid breakage, and the inner ends are led out through grooves in the fibre collars. The yoke, of Swedish iron, is $2\frac{5}{8}$in. wide, $2\frac{1}{8}$in. thick, and $7\frac{1}{2}$in. long. It is held in position on the cores by two $\frac{3}{8}$in. bronze studs, each threaded at the upper and lower ends, and furnished with a collar which fits into the counterbored part of the hole in the yoke. The studs are squared at the upper end to receive a wrench, and a nut is placed on each stud above the yoke for clamping it securely after adjustment. The machine is regulated or adapted to any work requiring less than its full power by raising the yoke more or less. The yoke is provided with an eye, by means of which the machine may be lifted.

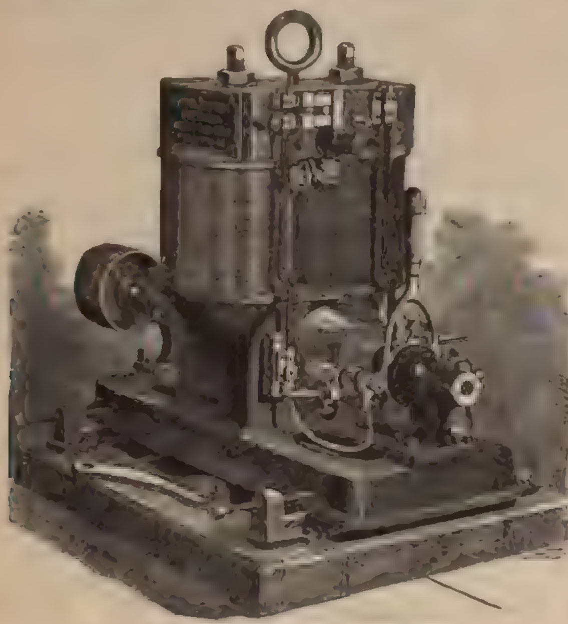
Front and rear boards of mahogany are arranged on opposite sides of the yoke, and held in place by brass plates at the ends.

The outside ends of the field magnet coils are connected with binding posts on the rear board.

A variable resistance of 10 or 15 ohms is inserted between these posts when the machine is used as a dynamo. In the front board, at the right-hand side, is secured a bronze casting, known as the right-hand motor head field magnet terminal. This is adapted to receive the line wire, also one of the leads, the upper end of which is screwed to the casting. The lower end of the lead is secured to a lead terminal attached to a block of wood secured to the right-

* From the *Scientific American*.

hand pole-piece. At the right-hand side of the machine a similar arrangement of the lead is found, but the upper lead terminal is made in two separate parts, one attached to the lead, the other being connected with the line; both being furnished with copper switch tongues. The switch arm turns on a stud projecting from the front board, and carries a loose triangular switch-plate of copper, having a knife-edge which readily enters between the switch tongues. The switch has a T handle of hard rubber, by means of which it is turned. A stop pin projecting from the front board limits the rearward movement of the switch arm.



Small Edison Dynamo or Motor.

The inside end of the right magnet coil is connected with the right-hand lead, and the inside end of the left-hand magnet coil is connected with the lower half of the left-hand lead terminal.

At opposite ends of the base there are plane surfaces, to which are secured the self-oiling bearings of the armature shaft. Each bearing has a hollow standard furnished with a cap which, together with a cross-piece in the hollow standard, forms a support for the spherical central portion of the bronze sleeve forming the journal box proper.

Side View of Field Magnet, Partly in Section.

This sleeve is shorter than the outer portion of the bearing, and is slotted across the top to allow two brass rings to ride upon the armature shaft. These rings dip in the oil in the hollow standard, and as they revolve carry oil to the shaft in quantities more than sufficient for the purpose of lubrication. The oil is distributed throughout the bearing by means of spiral grooves formed in the inner surface of the journal box. The surplus oil drops back into the hollow standard. A screw plug in the low[cut off] portion of the standard allows of the renewal of the [cut off] The bearings at opposite ends of the machine are [cut off]

Edison Switch.

except that the cast-iron support of the bronze journal b[cut off] at the commutator end of the armature, is turned on [cut off] inner end to receive the brush yoke.

(To be continued.)

THE ELECTRIC TRANSMISSION OF POWER.*

BY GISBERT KAPP.

LECTURE III.

As an example of a large modern transmission plant, I sele[cut off] for illustration, that erected a few months ago for the Sch[cut off] hausen Spinning Mills. This example is not only interest[cut off] on account of its magnitude, but because it has been pl[cut off] so to say, into the very stronghold of rope transmiss[cut off] namely, at the Falls of the Rhine, where the last generatio[cut off] Swiss engineers carried out such admirable work in teledyna[cut off] transmission that the present generation can only copy, [cut off] cannot improve upon it. And the grand example set [cut off] Redtenbacher, Amsler, and others, on the Rhine has, [cut off] matter of fact, been largely copied at other places. The[cut off] hardly a large engineering works in Switzerland or the South[cut off] Germany where rope transmission in some form or other [cut off] not be found, but the best days of this system are p[cut off] Till recently, rope transmission held the field absolutely, [cut off] because it was perfect, but because there was nothing be[cut off] Now, however, we have something better in electric trans[cut off] sion, and the flying ropes are being steadily replaced by [cut off] electric conductors. In the first place, the capacity of [cut off] dynamic transmission to deal with large powers is limi[cut off] During last year the Niagara Commission inspected a l[cut off] number of plants in Europe, and came to the conclusion [cut off] 330 h.p. is the very utmost which can be dealt with by a si[cut off] rope, so that above this power we must employ more ropes [cut off] a corresponding complication in the gear. I need hardly [cut off] that no such limit exists in electric transmission. But there [cut off] other difficulties in connection with ropes. They wear out [cut off] fast, their support at the translating stations on the line requ[cut off] the erection of very heavy and costly structures, and they [cut off] largely influenced by climatic changes, causing excessive str[cut off] at some times, and slipping at others. These considerati[cut off] have induced the managers of the Schaffhausen Spinning M[cut off] to adopt electric transmission in the very spot where [cut off] transmission, in years gone by, has received its most pe[cut off] development possible.

The situation of the works is shown on the diagram, Fig[cut off] The spinning mills are on one side, and the generating sta[cut off] is on the other side of the river, the distance between the [cut off] being about 750 yards. In the generating station there is [cut off] for five 350-h.p. turbines, of which four are now in place, [cut off] of these only two are as yet used in connection with the ele[cut off] power transmission I am about to describe. The power of th[cut off] turbines is sold to the Spinning Company at the rate of £2 [cut off] per annual horse-power taken off the rope pulleys, Fig. 2 [cut off] turbines are horizontal wheels, and their vertical axes [cut off] geared by bevel wheels with the rope pulleys, by which mo[cut off] is conveyed through cotton ropes to the two genera[cut off] dynamos. The latter are six-pole machines, each designed [cut off] an output of 330 amperes at 624 volts, and in regular w[cut off] these machines are coupled parallel. The machines, [cut off] in fact, the whole installation, with the exception of [cut off] hydraulic works, has been designed by Mr. Brown, to wh[cut off] I am indebted for the particulars I now bring before [cut off] The electrical part of the plant was made and erected by [cut off] Oerlikon Engineering Works. The line consists of four ca[cut off] (each having an area of ·437 of a square inch), and is [cut off] ported at four intermediate points, besides the supports [cut off] the terminuses. One of the intermediate supports is the [cut off] turbine-house, which in former times was used in connect[cut off] with the wire rope transmission; the others are towers of [cut off]

* Cantor lectures delivered before the Society of Arts.

ework, 46ft. high, one of which is shown to a larger scale 'ig. 1. The span where the line crosses the river is 330ft., where it passes along the shore of the river the span is t.

joint; whilst, at the same time, the strain is divided between all the wires in the most even way possible. The inner box is surrounded by an outer box, and the intervening space is cast out with sulphur, which is an excellent insulating material, and

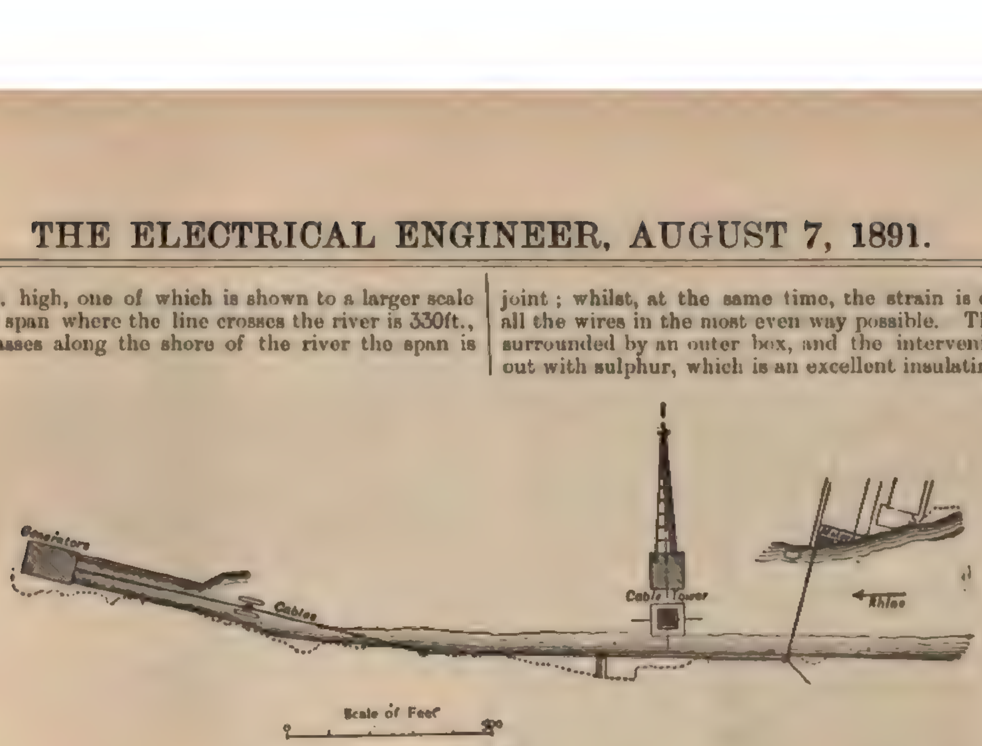


Fig. 1.

'ou may imagine that the proper support and insulation of :es of that size, and with so long a span, is a matter of con- rable difficulty. The use of glass or earthenware insulators on alk, as employed for the support of telegraph lines and other

applied in this way, of sufficient mechanical strength to resist the large forces involved in the supporting of these heavy cables.

In mountainous countries, where thunderstorms are frequent and violent, the protection of lines from lightning strokes is a

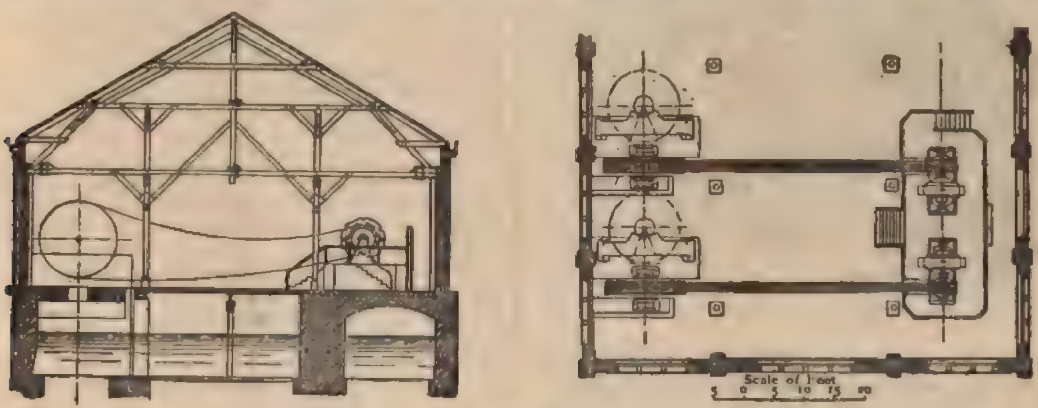

Fig. 2.

t wires, is, of course, out of the question. We must have some- ig very much more substantial, and this has been provided he manner shown, Fig. 5. Near the top of each post there bolted to the iron framework four of the boxes shown on

matter that must not be overlooked. The line I am describing is protected in a twofold manner. In the first place, there is stretched over the four electric cables a steel wire rope, passing right over the supports, and in good electric connection with

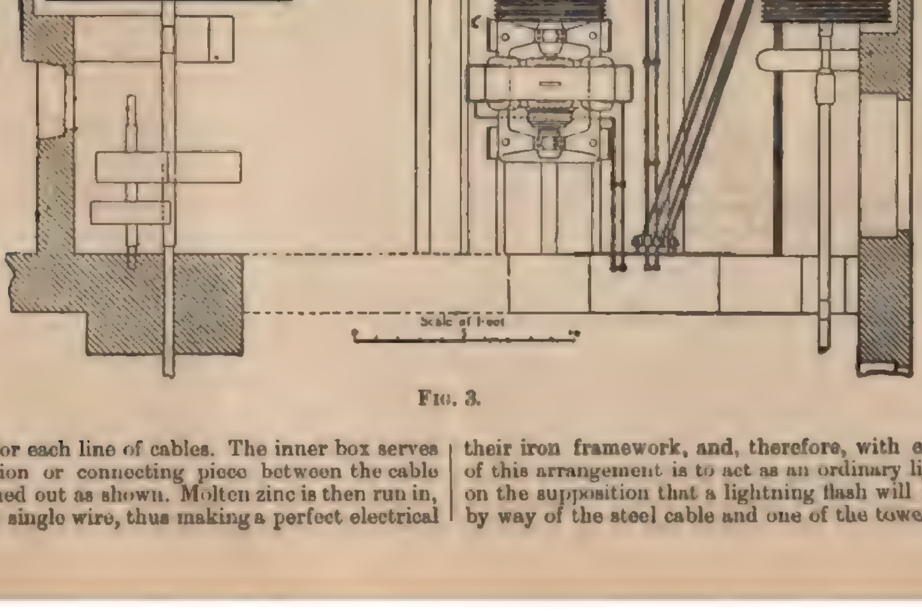

Fig. 3.

diagram; one for each line of cables. The inner box serves kind of junction or connecting piece between the cable , which are opened out as shown. Molten zinc is then run in, surrounds every single wire, thus making a perfect electrical

their iron framework, and, therefore, with earth. The object of this arrangement is to act as an ordinary lightning protector, on the supposition that a lightning flash will rather go to earth by way of the steel cable and one of the towers that run along

the electric line. But lightning flashes are sometimes very erratic, as was shown experimentally in this very room, in the admirable "Mann Lectures" which Prof. Lodge delivered before this society in 1888. It is, therefore, also necessary to make provision for flashes which will, for some reason or other, stray away from the direct path provided for them. And this has been done in the Schaffhausen installation by the employment of lightning arresters at both terminal stations. At each station there are four lightning arresters, one for each cable. They consist of a pair of toothed plates, of which, however, only one is fixed, the other being movable. When a flash strikes one cable only, it goes to earth by the corresponding plates, and no further damage is done. Should, however, both a positive and a negative cable be struck at the same time, then the arc set up between the plates by the passage of the lightning flash provides an easy path for the power current also; in other words, the generator will be short-circuited. The object of making one of the plates movable is to cut off the short-circuit current before any harm is done to the machinery. The movable plate of the lightning protector is connected to the core of a solenoid, through which the short-circuited current must flow. Immediately this current is started, the core is sucked in, and the movable plate falls away from the fixed plate, thus acting the part of an automatic switch.

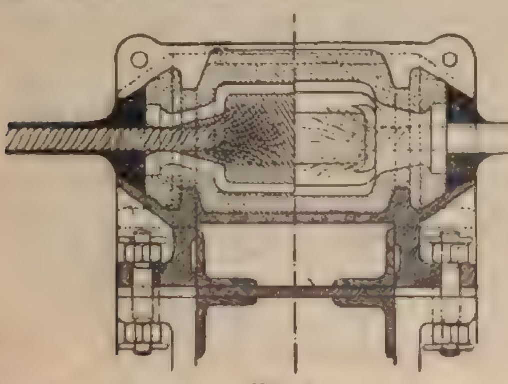

Fig. 5.

Returning now to the Schaffhausen plant, the generating station contains two 300-h.p. dynamos, which are over-compounded, so as to produce a constant pressure of 600 volts at the motor station, the loss in the line being with full current 24 volts. These machines have series-wound drum armatures, running at 200 revolutions per minute. Their more important electrical data, as well as those referring to the motors, are given in the following table:

Schaffhausen Transmission Plant.

	Generators.	Twin motor.	Small motors.
Number of machines	2	1	2
Normal horse-power	300	380	60
Number of poles in magnet field	6	6	2
Revolutions per minute	300	300	350
Terminal voltage	624	600	600
Normal current, amperes	330	500	81
Diameter of armature, inches	47½	42½	23¾
Length of armature core, inches	20	20¾	22½
Radial depth of armature core, inches	8	7	4¾
Section of armature conductor, square inches	·103	·078	·0287
Number of armature conductors	316	316	540
Number of commutator segments	153	153	90
Loss in armature resistance per cent.	1·46	1·52	2·7
Induction in armature C.G.S. measure	7,500	7,000	15,800
Shunt resistance ohms	140	143	295
Loss in shunt excitation per cent.	1·35	1·08	—
Main turns per magnet	6	4	—
Loss in main excitation per cent.	3	2	—
Type of armature	Drum	Drum	Cylinder

Fig. 3 shows the twin motor, which receives the bulk of the power at the spinning mills, whilst the remainder is taken up by a couple of two-pole motors, placed in other parts of the mills. These are not shown on the diagrams, as they are of the ordinary design, with which you are already familar. The twin motor is rated at 380, and each of the single motors at 60 h.p., making in all 500 net brake horse-power delivered to the mill shafting. The coupling between the motors and the mill shafting is by cotton ropes, as shown in Fig. 3, the arrangement chosen having the advantage that very little side strain is thrown upon the motor bearings, owing to the ropes pulling opposite ways.

An interesting and novel feature of the plant is the arrangement adopted for starting gradually, and yet without the use of resistance. In my experiments last week I used current delivered at constant pressure; and to start the motor gradually and prevent sparking at the commutator, I was obliged to use into the armature circuit a variable resistance, which was withdrawn after the motor had gathered enough speed to make it safe. There is no inconvenience in using such a resistance when we are dealing with small currents; but when it is a question of several hundred amperes and the absorption of as many horse-power, the resistance becomes a very cumbersome and unwieldy appliance. To get over this difficulty, Mr. Brown has devised a very ingenious method of coupling between the large machines, the essential features of which are shown in Fig. 6. As I have already mentioned, there are four main cables—two positive and two negative. Three of these cables contain no switches which need be used for starting, although, of course, they contain the switches and fuses which may be required for testing purposes and as safety devices, but these not being essential to the explanation of the starting arrangement I have not shown in the diagram. Call the two outer cables

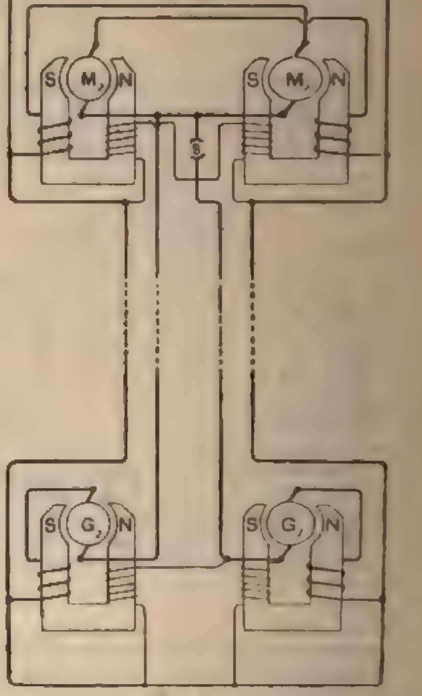

Fig. 6.

positive, and the two inner cables negative. The positive cables are looped at both terminuses, and the inner cables are also looped in this way, but a switch is inserted in the right-hand cable at the motor station. Now imagine all the machines at rest, and this switch to be open. To start the plant, the turbine-driven generator, G_1, is set in motion, and the speed run up till this machine excites itself by its own shunt. If you follow the connections you will find that the shunts of the other three machines will at the same time also become excited. The motors have now made their fields, and if we start the second generator, G_2, slowly, a power current of gradually increasing strength will be sent through both motors, and the latter will gradually start. As they gather speed, the counter E.M.F., which is indicated by a voltmeter at the motor station, gradually rises; and if it has become equal to the E.M.F. indicated by a second voltmeter in connection with the current from the first generator, G_1, the attendant closes the switch, and the operation of starting is completed. It should be noted that on closing this switch there is no sudden rush of current, since the pressure on both sides of the switch is approximately equal.

Originally, the motors were intended to be pure shunt machines; but it was soon found that, owing to the very small armature resistance and armature reaction, it was very difficult to get the load equally divided between them. Mr. Brown, to overcome this difficulty, hit upon the ingenious device of making the machines mutually control each other by putting on demagnetising main coils, and crossing the connections between armatures and fields, so that the machine which might at any moment develop a tendency to take more than its fair share of current would have its field strengthened by the deficiency of current passing through its main turns to the other armature, and would thus immediately raise its counter E.M.F., and check the excess of current, whilst the other machine which was not taking enough current would have its field weakened, and would thus be forced to take more current. It is clear that by this cross-connection even a neglect on the part of the attendant to set the brushes properly cannot materially influence the even division of current and load between the two machines. At the same time the demagnetising

influence of the main coils has the same effect as if the armature reaction were increased, and ensures thus constancy of speed, as I have shown you experimentally last week. In the diagram, Fig. 6, the machines are represented as if they had only two poles each. This I have done to make the diagram as simple as possible, and for the same reason I have shown the shunt and main coils on separate magnet limbs, but you will have no difficulty in translating in your own mind this principle of circuit connections to multipolar machines.

It may interest you to have a few details of a commercial nature regarding this transmission plant. The manufacturers have guaranteed a commercial efficiency at ordinary full load of 78 per cent., also that the machines must be capable of transmitting an excess of 20 per cent. over their normal power for one hour and a half without damage. The wear of one set of brushes to be not less than 2,000 hours, and the life of a commutator not less than 20,000 hours. The variation of speed of the motors between running idle and under full load not to exceed 3 per cent. The total cost of the electrical part of the plant, including cable towers and erection, was £6,800, or £13. 12s. per net horse-power delivered.

I have occupied some time in putting before you this transmission plant, because exact information about successful engineering work is of great value to practical men; and the Schaffhausen plant is certainly one of the best and most successful examples I could have chosen. The power transmitted is certainly large, according to our present ideas, but there is good reason to believe that—in point of magnitude, at any rate—this transmission will very soon be eclipsed by other work of this kind. There are projects afloat for utilising the power of the Rhine, near Bâle, to the tune of tens of thousands of horse-power, and at Niagara, as you all know, a total of 125,000 h.p., or a little over 3½ per cent. of the total power of Niagara, is to be taken from the Falls and transmitted to various distances, the longest distance being some 20 miles. I am not in a position to give you details of any of the schemes which have been submitted to the Niagara Commission, since these are the property of the Cataract Company, but by the courtesy of several members of the Commission, notably Dr. Coleman Sellers, I am able to give you a general outline of the schemes. My object in applying to the Niagara Commission for information of this kind was to obtain some indication of the opinions which leading modern engineers entertain of electric power transmission, and to put the result of my enquiry before you. Lest the general condition of the Niagara scheme may not be quite familiar to all of you, I shall now throw upon the screen a picture of the Falls, and give you very briefly an outline of the objects for which the Cataract Company has been established.

Of the immense power represented by the descent of the river from its upper to its lower level over the Falls (about 3½ million horse-power), there is utilised at present an aggregate of only about 5,000 h.p. in the mills you see on the left of the picture. The water is brought to these mills by a surface canal from the upper reaches of the river, and, after passing through turbines, is discharged into the open air about half-way between the level of the ground and the level of the river below the tail races, forming a number of miniature waterfalls. Only about half the available head is therefore utilised. If the system adopted hitherto could be followed in future, there would be little difficulty in establishing a station for the generation of any amount of power in this locality, but there is a strong tide of public opinion against the establishment of any more hydraulic works on the river bank, to say nothing of the difficulty of finding room for them and the open-air canal which would be required. The Cataract Company have therefore resolved to carry out their operations, to a great extent, underground; and at the present moment are driving a tunnel 30ft. high by 20ft. wide, and about 6,700ft. long, which is to serve as a tail race for the water coming away from their power station. This tunnel is shown on the picture by two dotted lines, and its mouth is partly submerged under the level of the lower river. The total fall between the upper and lower river is 200ft., and the net fall available for the turbines is 140ft. The fact that the tail race is a tunnel, necessitates the turbines being placed at least 110ft. underground, since the suction tube of a turbine cannot be made longer than the column of water which can be balanced by atmospheric pressure, and this increases very materially the engineering difficulties of the work.

Last summer the Cataract Company invited a limited number of engineers to send in projects for the creation and transmission of power, and instituted a commission, under the presidency of Sir William Thomson, to investigate and report on the projects. There were in all 20 competitors, but of these only 14 complied with the programme drawn up by the commission, and were therefore held to be qualified to have their projects examined. Of these 14, eight competitors sent in combined projects for the creation and transmission of power, four referred only to the creation, and two only to the transmission of the power. The point of interest to us is what methods were suggested by the 10 qualified competitors in transmission. The question is somewhat complicated by the fact that some competitors have suggested mixed systems of transmission, and that in classifying the schemes into electrical, pneumatic, and hydraulic, we must count some competitors twice over. On this basis I find that the following represents the transmission projects: Electrical seven, pneumatic six, hydraulic two. It is certainly remarkable that the balance in favour of electric transmission should be so small. And it is equally remarkable that there should have been as many as six competitors who either wholly or partly advocated pneumatic transmission. The experience of colliery managers goes to show that even over the comparatively short distances over which they use pneumatic transmission, the total efficiency lies generally between 20 and 30 per cent., and does certainly not exceed 40 per cent. We cannot suppose that engineers who have sent in pneumatic projects are ignorant of this fact, or at any rate we must suppose that the majority of them are quite aware that high efficiency cannot be expected from compressed air transmission. If, nevertheless, they have adopted compressed air in preference to electricity, it must be for one of two reasons. Either they have no confidence in the capabilities of electric transmission, or they consider the cost so high that the interest on the extra capital and the greater depreciation of the plant will more than counterbalance the advantage of high efficiency. It cannot be denied that in the present state of our knowledge of electric transmission, there is some ground for both these views. The Niagara problem is unique both in magnitude and distance, and I am bound to confess that we electrical engineers are at the present moment not quite prepared to face it. At the same time I must say that I feel convinced that in a few years from now there will be not one, but a dozen men ready to face this problem with a very good chance of successfully solving it. As a matter of fact, we are at present on the threshold of a new system of electric power transmission. The old system of using continuous currents and ordinary dynamos has been perfected to a point which leaves little to be desired, but it has its limits, and, unfortunately, the Niagara problem, or at least a part of it, is just a little beyond these limits. Hence we find that only about half of the competitors have had the courage to propose electric transmission. Of these, only two suggested the use of alternating currents at voltages of 5,000 and 10,000 respectively; the others followed the old lines of continuous-current transmission at voltages varying between 1,600 and 4,500 volts.

This brings me to the consideration of a subject which is of great importance not only in regard to the Niagara problem, but to long-distance transmission generally—namely, the limits of distance up to which the usual system of transmission is practicable. If you will refer to the table giving the cost of transmission plants, given in my last lecture, you will find that, for large powers at any rate, an increase of distance up to four or five miles does not make the cost prohibitive, and you will conclude from these figures that, within a five-mile limit, the old system of electric transmission is certainly feasible. How much farther you might go is a matter for theoretical consideration; the table does not help you much, as the only example of a very long-distance transmission is one where the power is small, and is therefore, in a certain sense, misleading. I have given you a formula by which you can calculate the most economical voltage for any distance; and if you do this for many cases, taking, for instance, 500 h.p. as your unit of power, you will find that as the distance increases beyond about five miles, the economical voltage begins to grow beyond the limit which might be considered practicable for one machine. It is quite impossible to lay down hard and fast rules. Under certain conditions, especially if you have to transmit cheap water power, you may possibly reach a distance of 10 miles before getting to the limit of voltage; but whatever may be the special conditions of the problem, there is a limit of distance beyond which a single machine will not reach. "Very well, then," you might say, "if a single machine cannot be made to give the required pressure, let us put two or three machines in series." To correctly appreciate such a suggestion, let us first of all see what limits the voltage of a machine. Two things limit it, the commutator and the general insulation. Practical dynamo makers will tell you that in large machines they are quite prepared to put 1,000 volts on the usual Pacinotti commutator—if necessary, they will go to 2,000 volts, but with some misgiving; and if you ask them to make a machine for 3,000 volts, they will, as likely as not, refuse. I do not refer to the Thomson-Houston or Brush machines, which have special commutators, but to large machines giving an even current and a high efficiency, such as we require in the transmission of power. We may thus conclude that 2,000, or, at the outside, 3,000 volts, is the limit of voltage to be obtained from a single commutator. But the general insulation of the machine must also stand this pressure, and where, as in dynamos and motors, the insulation consists of cotton, paper, fibre, varnish, and like materials, which are subjected not only to electrical, but also to mechanical strains, 3,000 volts is quite high enough for safe working. The commutator difficulty can of course be got

over by putting several machines in series and insulating their frames from earth. The difficulty of general insulation can, however, not be met so easily. This you will see by referring to Fig. 7, which shows diagrammatically three 2,000-volt machines placed in series. Shunt excitation at the high pressure of 2,000 volts is, of course, out of the question; series excitation introduces complication and certain difficulties, especially at the motor station; and separate excitation, although simple and easily worked, has the disadvantage of throwing great electrical strains upon the insulation between the exciting coils and the frames of the machines. Imagine, for instance, that there is a weak place at A, between the exciting coil and the frame of the first machine, then the strain between the exciting coil and the frame of the third machine at B will be about 6,000 volts, even if all the machines are perfectly insulated from earth. With series self-exciting machines, the strain would of course be limited to 2,000 volts, but there still remains the difficulty that all the armatures would have to be mechanically connected by insulated couplings, and there would also be great danger in touching even the iron frame of any machine. You see the use of several machines in series is not such an easy matter as it may look at the first glance, and this method has, as far as I know, only been adopted in cases where the total voltage was under 2,000.

The net result of our investigation may be stated by saying that the electric transmission of power by continuous currents is economical and safe up to distances for which the most economical voltage does not exceed 2,000, or, at the outside, 3,000 volts, but that beyond these distances some other system must be applied. That this other system must also be electrical is evident, for we know perfectly well that distances beyond the reach of our present electric transmission systems are hopelessly beyond the reach of lines of shafting, flying ropes, air, or water. Now, what is this new electrical system which shall enable us to carry power over 10 or 20, or perhaps 100 miles.

In attempting to answer this question I must perforce leave the safeground of solid facts and engineering practice, and enter into the domain of speculation. Yet speculation based upon experimental results which, in themselves, are as reliable as were those experimental results which have led to the practical development of electric power transmission as we know it now.

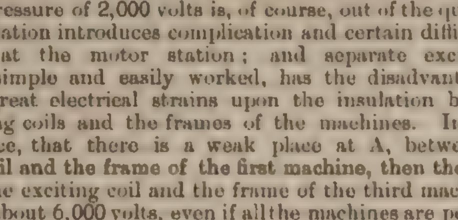

Fig. 7.

The starting point in the theory which I have now to bring before you is the well-known disc of Arago. If a copper disc be rapidly revolved under a compass needle, the latter is also set into rotation. I am able to show you this experiment, by the kindness of the Science and Art Department, who have lent me the apparatus you see before you. Between the copper disc and the compass needle is placed a sheet of glass so as to prevent air currents from affecting the needle. If I set the disc in motion you see that the magnet very soon follows. To make the motion of the latter better visible, coloured pieces of paper are attached to the poles. Now the fact that the magnet revolves is evidently due to there acting upon it some mechanical force. The explanation is perfectly simple. The disc, in passing under the poles of the magnet, becomes the seat of a very complex system of E.M.F.'s, which produce an equally complex system of currents. Some of these currents cross the path of the lines of force emanating from the magnet, and thus mechanical forces are set up between the disc and the magnet, causing the latter to rotate. It is as though there existed between the disc and the magnet a kind of electro-magnetic friction by which the magnet is dragged after the disc. Since all motion is relative, it is perfectly clear that we might regard the magnet as revolving, and then the disc will be dragged after it. With the apparatus before you this experiment would not succeed, since the magnet is small and the disc is heavy; but if we were to employ a very strong magnet, and revolve it rapidly enough, there would be no difficulty in setting the disc in rotation, and even obtaining power from it. I have said a moment ago that the system of currents set up in the disc is very complex, and you will easily see that only those currents which are more or less radial, and of these only their radial components, are instrumental in exerting mechanical force, whilst all the other currents represent simply so much waste power. To make an efficient machine we must, therefore, not employ a continuous disc, but a system of conductors, so arranged as to force the currents to flow as much as possible in a radial sense, and only in those places which are immediately under the influence of the magnetic field. Or, better still, we may abandon the disc shape of conductors altogether, and substitute an armature with a laminated iron core of the drum type, seen end on in Fig. 8, and use, instead of a straight magnet, a horseshoe magnet, so shaped as to bring its poles N S, to opposite sides of the drum, and wind the latter with a number of coils closed in themselves. If we now revolve the magnet, strong currents will be generated in each coil successively, and a very strong torque will be exerted on the armature. The torque will, in fact, be comparable to that required to revolve an ordinary continuous-current drum armature in a strong field if we short-circuit the brushes. Here, you see, we have, by applying a few very obvious improvements to the Arago disc, at once obtained a machine of very considerable power.

Fig. 8.

Imagine both the magnet and the armature mounted on independent spindles (not shown in the diagram, but passing here at right angles through the centre of the figure), then it is perfectly clear that power given to the magnet spindle is transmitted by electromagnetic induction to the armature, and a large portion of it may therefore be obtained again from the armature spindle. Here we have, certainly, transmission of power, but not of the kind we require, since the distance of transmission is nothing. Now, what we want to do is to alter our machine so as to separate the two parts. We want the magnet in one place and the armature in another, miles away. If, in this case, we succeed in transmitting power from the magnet to the armature, then we shall have solved the problem. This problem has been solved by an Italian electrician, Prof. Galileo Ferraris, of Turin, who, early in 1888, communicated to the Turin Academy the results of an investigation on rotating magnetic fields produced by alternating currents. To clearly see the bearing which Ferraris's investigation has on our problem, let us enquire what it is we want at the motor station. We want there an armature, as shown in Fig. 8, and a magnetic field, the lines of which shall pass through the armature, and shall revolve round its centre. Whether the field is due to a real magnet, or is produced by any other means, is immaterial; and it is the merit of Ferraris to have shown us how to produce such a revolving field without the use of a real magnet, but simply by the use of two distinct alternating currents passing through fixed coils.

As the subject is new, and will not be found in any of the numerous text-books dealing with electrical engineering, you will perhaps not think it out of place if I put it before you in rather an elementary manner, beginning with the simplest possible case, and passing gradually to the more complicated cases. Assume, then, a combination of apparatus, as shown in Fig. 9. Here you have on the left an annular iron core wound with two coils which are connected in series, and to a pair of line wires going to a similar coil on the right, which may be at any distance. Into the circular space enclosed by the first coil we put a straight bar magnet, N S, which can revolve round its centre. As the poles sweep past the wire turns and E.M.F. is induced, and a current is caused to flow, the direction of which changes twice in every revolution. We

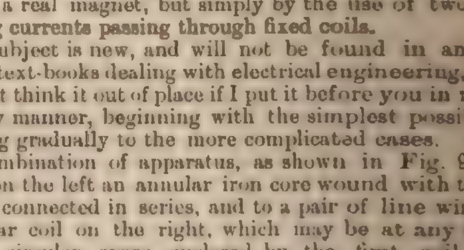

Fig. 9.

have here, in fact, an ordinary alternate-current generator with stationary armature and revolving field magnet. By suitably proportioning and placing the various parts of the apparatus, we can make the E.M.F. and the current curve of a true sine character; and, in order to simplify the treatment, I shall assume that in this, and in the cases which follow, the design is such that all the E.M.F. and current waves follow the sine law. The alternating current, in passing through the coils on the right, magnetise the iron core, so as to develop north and south polarity in the line M_1, M_1. The effect is the same as if we placed into the ring a vertical magnet which is collapsible, the two poles shrinking into a point at the moment that the current strength is zero, and coming apart vertically as the current increases.

(*To be continued.*)

OSBO-PREMIER PRIMARY BATTERY.

attery has been designed under the above name for supplying o small installations up to 30 lamps or so. The cell is of gle-fluid type, of carbon and zinc, and contains, in addition, idising apparatus for reoxidising the depolariser, which es reduced in the course of working by the nascent gen. Besides the outer vessel and the elements, the cell ns a porous tube with perforated bottom. This tube is y packed with the depolariser, and only requires renewal six to nine months. In the upper part of the porous pot ass tube (with side tube and glass stopper), the side tube down into the depolariser itself. When it is to be used, a ising bag is put in the tube with the addition of a little , and the tube closed. A chemical action is thereby set up, results in the liberation of oxygen, which flows through the nto the depolariser, hence reoxidising that which has been d.

reoxidising bag consists of a special mixture of chloride of with a few crystals of nitrate of nickel; this, when upon by water or moisture, disengages oxygen, more ally if warmed. The battery solution provides for this, as sequence of the chemical action it is always slightly above mperature of the surrounding air. There is no action on circuit with this solution, as the zincs are heavily amated; nor is there smell or fumes. If it were or the formation of zinc salts in the working of the the same solution might be used indefinitely. The y solution has to be changed, not because the depolariser austed, but because the solution becomes finally clogged he zinc salts. Theoretically, the battery may be said to run nsumption of zinc and chloride of lime. The 12-cell battery ed to run 30 hours, yielding a constant output of 14 amperes volts, and using 30lb. of zinc at 2¼d., 2¼lb. of depolariser at nd two dozen reoxidising bags at 2½d. per dozen. The cost s given as $14 \times 24 \times 30 = 10{,}080$ watts, or 10 B.T.U. for a cost The labour of changing is small. The battery seems an sting departure, and we are informed that an installation hortly be exhibited in London showing the battery in tion.

LEGAL INTELLIGENCE.

IPTON AND CO., LIMITED, v. PHILLIPS.—PHILLIPS v. CROMPTON AND CO.

The Lighting of Chelmsford.

Court of Appeal (Lords Justices Lindley, Bowen, and Kay) red judgment on Wednesday in this case. It was an appeal y of motion for a new trial from the decision of Mr. Justice nd a special jury in an action brought in the Queen's Bench on by Messrs. Crompton and Co. to recover damages for loss ned by reason of defective wire supplied to them by Messrs. ps Bros. for the lighting of the town of Chelmsford, the t being given for the plaintiffs.

Finlay, Q.C., and Mr. R. W. Wallace were for the appel- and Mr. Moulton, Q.C., and Mr. J. C. Graham for the ndents.

d Justice Lindley said the matter was of nterest, not only to arties, but to persons interested in electric lighting. The tiffs were contracting to light Chelmsford, and applied to the dants, who were well-known manufacturers, for wire. A was therefore written by the plaintiffs to the defendants g they would require 4,000 yards of wire, and the letter said, ase quote for B and C qualities; your terms must be special." defendants replied, "We have much pleasure in quoting l prices for B and C qualities." Then an order was given ,000 yards of "C quality, to be at least ·012 thickness of r when vulcanised." The defendants supplied a large tity of the wire, which the plaintiffs put up in the open air nprotected. The wire proved unsatisfactory, and they had ke it down. The plaintiffs paid for the wire, and brought ction against the defendants to recover damages. Mr. ce Day from the beginning to the end had directed the jury that nly question they had to consider was whether the defendants supplied the plaintiffs with C quality wire—merchantable C ty wire. He told them distinctly that there was no guarantee e letters, but it must be merchantable C quality wire. In to ascertain what this was it was necessary to look outside ocuments, and it was admitted that C quality wire was not a of wire generally known in the trade, but a quality of wire and sold by the defendants. It was a term used by them to e a particular article. Looking outside the letters, they were ght to the question—to his mind a cardinal question—and the question they were discussing, did C quality mean covered or insulated wire? If it meant covered wire the defendants' performed their contract, and if insulated was meant, they ot performed their contract. Evidence of this kind was to tained partly from what occurred, partly from the defendants' nce, partly from a telegram which referred to the question of tion, and partly from a letter from the defendants, and putting together, it appeared to him impossible to say that there was idence which warranted the jury in finding that C quality t wire, and not covered wire. If they once got to the starting point that the order was for insulated wire, the evidence was overwhelming that this was not insulated wire, and it was impossible to disturb the verdict. It had been argued with very great force by Mr. Finlay and Mr. Wallace that the failure which had arisen was attributable entirely to the fact that the plaintiffs applied the wire to a purpose for which it was utterly unsuited. That was perfectly true, but how it came to be so applied? The answer was that the plaintiffs assumed, and had a right to assume, that it was merchantable C quality wire—in other words, insulated, as distinguished from simply covered wire. It was no answer to say that this covered wire was amply sufficient for all indoor purposes. Uncovered wire, with proper protection where it came into contact with conducting surfaces, would be sufficient for indoor purposes, but the moment the jury found themselves entitled to treat the wire as insulated, the case for the defendants failed. The verdict was a curious one. Mr. Justice Day had placed great stress from first to last upon the point that the only matter the jury had to consider was whether the wire supplied was C quality, and the reason he did that was that attempts were made to bring in other topics—for example, that the wire ought not to have been applied to outdoor purposes. Mr. Justice Day had set himself resolutely against that. The verdict was, "We find for the plaintiffs, but we feel that Messrs. Crompton have been guilty of contributory negligence in not examining the goods, which were an exceptionally bad article." It was said by Mr. Finlay and Mr. Wallace that exceptionally bad meant exceptionally bad for the purpose to which it was applied; that it ought never to have been applied to an outdoor line, for then it was exceptionally bad. But the defendants said they had never meant it for that purpose. He (Lord Justice Lindley) thought, however, that it was susceptible of the meaning that it was an insulated wire, and that it was an exceptionally bad article of the kind as an insulated wire. What the jury meant by the expression "contributory negligence," was an intimation that when the jury came to consider the question of damages they were not going to give the plaintiffs the cost of putting up and taking down the wire, because they ought to have examined it. As it appeared, the question of damages never went to the jury, because the damages were referred, and he supposed the gentleman who had to deal with the question would take the same view. It appeared to him (Lord Justice Lindley) that it would be utterly unreasonable and wrong to give the plaintiffs all the cost of putting up and taking down the wire, because they could have discovered without the slightest trouble that the wire was unfit for the purpose. It was impossible to say that the verdict was against the weight of evidence, or that there had been such a miscarriage of justice as would warrant a new trial. He attributed the unfortunate misunderstanding which had arisen entirely to the ambiguity of the words used. If the defendants had sold this as covered wire, there would have been no difficulty.

Lord Justice Bowen said he entirely agreed.

Lord Justice Kay said he also entirely agreed. It appeared that the defendants made several qualities of wire, and on their cards they used the words "Electric Light Leads" and "Manufacturers of Telegraph Wires of any Specification." There could be no doubt, looking at the card, that their wires were meant for electric lighting. On the card, C quality was described as "vulcanised indiarubber insulation"; D, of a higher quality, was described as "vulcanised indiarubber higher insulation." Therefore, the card represented C as a wire insulated, it being covered with vulcanised indiarubber. It was plain that the person who wrote the first time did so with the defendants' card before him, and that he was ordering insulated wire. Of that there could be no kind of doubt. Then if he ordered insulated wire, the defendants sold this C wire as they described as insulated wire. During the progress of fixing the wire at Chelmsford the plaintiffs were anxious to know what was the resistance of this insulation, and they got an answer from the defendants that the approximate resistance of No. 14, C quality, was 250 ohms per unit; 250 ohms per unit they were told would carry an enormous current of electricity, and be a very perfect insulation indeed. Counsel in the Court below had admitted that the proper mode of testing the wire was by placing it in water and passing a current through it, and he (Lord Justice Kay) found in the shorthand notes that one of the plaintiffs' witnesses, Mr. Kemp, had said this was the proper method of testing, and counsel for the defendants had concurred. And evidence was given by Prof. Jamieson, which was quite uncontradicted, with reference to a report which was made by someone else, and had been approved by him, to the effect that the report contained a statement that the installation of the wire was so bad that the electricity ran through it so quickly that it would give no practical insulation whatever; and in answer to Mr. Justice Day, Prof. Jamieson had said that the insulation was so leaky the current was all drawn away, and at the further end they could not get a current at all. So that in some specimens of the wire the whole of the current escaped, from the imperfections of the insulating covering. If that wire was sold as insulated wire, and bought as insulated wire, the question was, Was it in fact insulated wire? The test of insulation showed that some parts of the wire were so bad that no current would go through, and other parts were proved to be exceedingly defective. Upon this evidence the jury might well find that, whatever C quality meant, it meant at least that the wire was insulated, and this wire was either not insulated at all or it was insulated so imperfectly as not to deserve to be called insulated wire. He did not say whether they were right or wrong, but there was ample evidence to go to the jury to justify their finding that this wire was not the wire which the plaintiffs contracted to buy; that being so, it seemed to him quite impossible that the Court could in any way disturb the verdict.

Motion refused accordingly.

NEW COMPANIES REGISTERED.

Electrical Assets Purchase Company, Limited.—Registered by Robinson and Stannard, 19, Eastcheap, E.C., with a capital of £1,000 in £1 shares. Object: to acquire the undertaking of the Liepmann Carbon Company, Limited, including certain patents relating to improvements in the manufacture of carbon for electric lighting, and to work the same, in accordance with an agreement, made July 13, between the Liepman Carbon Company, Limited, of the one part, and C. E. H. Hoskins of the other part. With slight modifications, the regulations contained in Table A apply.

Epstein Electric Accumulator Company, Limited.—Registered by A. L. Foley, 2, Maisemore-mansions, South Hampstead, with a capital of £101,000 in £1 shares. Object: To acquire certain patents and patent rights relating to improvements in the manufacture and use of secondary or storage batteries, and to carry on the business of an electric light and power company in all its branches, on the Continent of Europe or elsewhere. The first subscribers are:

	Shares.
Sir J. D. Mackenzie, Bart., Worcester Park, Surrey	1
H. G. Rawson, 6, Pump-court, Temple	1
L. Epstein, 5, Cambridge-villas, East Twickenham	1
J. Maier, Ph.D., 23, Melrose-gardens, W.	1
G. T. Broadbridge, 55, Doddington grove, Kennington Park, S.E.	1
F. Harland, 69, Lavender-sweep, Clapham Common	1
J. Davies, 46, Derby-road, Croydon	1

There shall not be less than three nor more than 12 Directors; the first shall be elected by the subscribers to the memorandum of association. Qualification, holding shares. Remuneration to be determined in general meeting.

Morecambe Electric Light and Power Company, Limited.—Registered by T. R. Hargreaves, 9, Bridge-street, Westminster, with a capital of £15,000 in £1 shares. Object: to acquire the undertaking of the Morecambe Electric Light and Power Company now carried on by T. R. Andrews and T. Preece, in accordance with an agreement made June 27 between the said T. R. Andrews and T. Preece of the one part, and J. Jowett on behalf of the Company of the other part, and to carry on in all its branches the business of electricians, electrical and mechanical engineers, etc. Registered without articles of association.

COMPANIES' MEETINGS.

ANGLO-AMERICAN TELEGRAPH COMPANY, LIMITED.

The half-yearly general meeting of this Company was held on Friday last at Winchester House, the Marquis of Tweeddale presiding.

The **Chairman**, in moving the adoption of the report, stated that the dividend of 12s. per cent. on the ordinary stock was a little disappointing to the Directors, but he did not think that anyone who was acquainted with the state of affairs, more especially in the commercial world, during the period under review, would be surprised at this result. Owing to the interruption on the west coast of South America their traffic had been reduced by £10,000. He was glad to say that the interruption which had so long existed was now removed, and that their traffic in that quarter was resuming its normal condition. He was quite satisfied that they had not suffered in any degree more than their competitors in the Atlantic. They had provided a through wire from Paris to Brest and Havre, and had thus placed themselves on an equality with their competitors in that country. At their last meeting one of their largest shareholders and customers complained that the Company's lines were subject to interruptions in the winter which greatly interfered with his business. He was glad to say with respect to this matter that the Western Union Company had shown themselves alive to the necessity and importance of placing the communications under their control in a far more satisfactory condition. The able general manager of that company had written them a letter in which he stated that, even with a repetition of the unparalleled weather of last winter, the precautions they had taken would prevent any unappreciable delay in the business on this company's side. The Directors had also determined to take steps to connect Sydney and Canso by cable, and in this way they would have direct communication by submarine cable between England and France and New York, which they had never hitherto had. The short line known as the North Placentia cable had given them a great deal of trouble, and would require some additional cable in order to make it as efficient as it should be. The renewal fund had reached the handsome sum of £990,000, and at current prices was worth about £29,000 more. It might interest them to know that during the last $4\frac{1}{2}$ years they had charged the renewal fund with repairs and renewals, costing about £120,000, being at the rate of about £27,000 a year, while the income from the renewal fund was about £32,000. He then referred to the suit between the Company and the Paris and New York Telegraph Company, and said that on the 1st of May the Council of State set aside the order of the Court of Prefecture of the Seine, and determined that the letter of M. Granet of the 30th of December, 1886, had not the effect of an order compelling the French company to break the contracts, but that it only amounted to an invitation to the French company to take immediate steps to put itself right according to the conditions of its concession. Since the date of that judgment there had been a correspondence between the French company and its Government, from which it appeared that the present Government would not sanction the joint purse agreements. The case would now go back to the Court of Appeal, which would decide—and, he hoped, finally—the amount of damages to which this Company was entitled through the unjustifiable conduct of the French company. There was no doubt that a gross breach of agreement was committed; but whether the French Court would see fit to give the Anglo-American Company considerable damages on this account or not, he would not venture to predict.

Mr. Francis A. Bevan (the deputy chairman) having seconded the motion,

Mr. Thomas Smith (York) proposed an amendment in favour of the payment of a higher dividend and rejecting the report. He contended that the expenses incurred by the opening of new offices ought to have been charged to capital and not to revenue, and that, if necessary, the dividend should be supplemented out of the renewal fund.

Mr. Brandon seconded the amendment, and complained that the deferred stockholders had received no dividend for seven years.

Mr. Wreford and **Mr. Jackson** endorsed the views of Mr. Smith.

The **Chairman**, in reply, said that the amendment was out of order. He maintained that the cost of the new offices could not have been debited to the renewal fund, and that rent could only be charged to maintenance. They could only pay a dividend out of net receipts; and he repeated what he stated at the last meeting with regard to the renewal fund—that it had always been recognised that £1,000,000 was the very least that they should have to their credit, having regard to the age and condition of the cables, and the necessity some day of renewing them. It would be idle to suppose that at the present time they could realise at the existing middle quotations, the investments forming the renewal fund.

The resolution was eventually carried by 13 to six.

COMPANIES' REPORTS.

BIRMINGHAM CENTRAL TRAMWAYS COMPANY, LIMITED.

Directors: Joseph Ebbsmith, Esq. (chairman), M. J. Sant, Esq., William Neale, Esq., W. J. Carruthers-Wain, Esq., A.M.I.C.E (managing director).

Report of the Directors, to be submitted to the shareholders at the tenth ordinary general meeting, to be held at the Queen's Hotel, Stephenson-place, Birmingham, on Tuesday, the 11th inst., at 12.30 p.m.:

The traffic of the Company continues to show a satisfactory increase, but the working expenses of the year have been excessive. The unsettled conditions of the fuel market has severely affected profits, especially those of the steam lines. Corporation charges for maintenance of the permanent way have far exceeded the estimates based upon previous experience. The rearrangement of working hours and wages has secured the goodwill and contentment of the servants of the Company, but has materially increased working expenses. Taken as a whole, however, the shareholders may view the year's working with satisfaction. The cable lines have more than maintained their earning capacity, and the electric lines, which in the first half of the year were suffering from exceptional difficulties of construction and maintenance, have apparently overcome those difficulties, and show a substantial profit, which is steadily improving. The comparative statement of traffic and profit is subjoined (Table A). The revenue account shows a balance of £25,657. 16s. 9d., to which has to be added the sum of £6,124. 7s., brought forward from last year's accounts, making together £31,782. 3s. 9d. Your Directors recommend: 1. That the sum of £10,000 be placed to reserve account against depreciation. 2. That the payment of the dividend upon

GERMAN CONTINENTAL GAS COMPANY.

The *Journal of Gas Lighting* gives an abstract of the report of this Company, from which the following extracts are taken:

"The Company have sought unremittingly to encourage the introduction of gas for heating and the production of motive power, not only by the manufacture of suitable appliances, but also by reducing the cost of installations to the consumers. The construction of large gas engines has commenced successfully. During the past year this work extended to the production of twin motors of 140 h.p., built in England on the 'Otto' system; whereas during the erection of the Company's electrical station at Dessau, in 1886, the largest gas engines known were twin motors of 60 h.p., and gas motors of 100 h.p., with four cylinders, were introduced for the first time in 1889. All experience and theoretical considerations up to the present justify the assumption that the sphere of usefulness of gas engines is by no means limited to small motors; but that, in fact, it will continually extend in the direction of power producers of great magnitude, inasmuch as, under such circumstances, there is simultaneously a substantial reduction in the consumption of gas per horse-power. This progress in the construction of gas engines is, moreover, of importance for the production of electric light in large centres; since even at the present time the Company are in a position, by means of a single 140-h.p. twin engine, in conjunction with adequate accumulators, to feed 4,000 incandescent lamps burning simultaneously, which corresponds to an installation of 5,000 lamps. Three such motors placed side by side, like steam engines are at the present time, could keep going an installation of 15,000 16-c.p. glow lamps, which would be sufficiently extensive for very many towns. But then all predictions indicate that the construction of gas engines will not remain long at 140 h.p.; and the combination of electrical concerns with the present gas institutions, besides showing a reduced cost of management, offers, when compared with a steam engine installation, the advantage that the supply station may be placed in the very centre of a town, in the heart of the electric light system, which, moreover, would diminish the cost of cable laying without fear of trouble from smoke or explosions, with smaller requirements as regards ground, and consequently lower rent. The competition of the electric light has, up to the present time, not impeded anywhere, within the range of the Company's activity, the natural increment in the output of gas; in fact, the latter, as formerly, is influenced primarily by the commercial position of industrial matters and general business activity. The statistics relating to the different stations of the Company show that all of them augmented their production of gas, as well as recording increments in the number of lights. The largest proportional increase was at the Hagen-Herdecke-Haspe station; the increase being 18·69 per cent. on the previous year's production, and 13·73 per cent. on the number of lights. The growth of the gas supply from this station has within the past three years made the Company attain a supply approximating to that which they had immediately before the opening of the competing municipal gas works in 1888. The reduction in the consumption of gas at the Hagen railway station since the 1st of January will, therefore, presumedly soon again be counterbalanced; and, in fact, the sale of gas at a better price will help this. But the success of the Company was considerably prejudiced by the assessment for the communal rates, about which contradictory decisions have been expressed by the higher administrative body, which will necessitate an appeal to the superior Courts. The lowest proportional advance is recorded from the Warsaw Praga station, with 2·19 per cent. increase of production, and only 0·57 per cent. lights above the number for 1889. This is wholly attributed to the bad state of commerce and industry. Intermediate betwen these come the stations at Frankfort-on-the-Oder, Potsdam-Neuendorf, Luckenwalde, Minchen-Gladbach-Rheydt-Odenkirchen, Nordhausen, Lemberg, Gotha, Herbesthal, and Ruhrort. At the last station, Herr F. Hannibal was appointed manager in place of Herr Wagner, who was transferred to the Dessau station, where the production was 10 per cent., and the number of lights 9·51 per cent., more than in the previous year; while the electrical department showed, in comparison with 1889, the following increments: Production in ampere-hours, 33·754, or 10 per cent.; number of arc lights, 5, or 9·26 per cent.; number of incandescent lamps, 141, or 4·61 per cent. The total illuminating power of these additions, reduced to 16 candles, was 124, or 3·46 per cent. The completion of the new battery of accumulators mentioned in last year's report has increased the supplying capacity as well as diminished the working expenses of this station, so that the average consumption of gas per horse-power was 0·750 cubic metre, as compared with 0·953 cubic metre in 1889. The average efficiency of these accumulators for the year amounted to 78·9 per cent.—highly satisfactory figures when one takes into consideration how very unfavourable the extremely small summer demand is for the utilisation of the accumulators. The financial results of this station—opened Sept. 13, 1886, and, next to that in Berlin, the oldest central station in Germany—were for the first time to a certain extent gratifying, for though the average age of the lamps for the year was only 180 instead of 500 hours, and their profitableness depends on their hour-burning capacity, there has been some recompense in improvements in the construction of motors, dynamos, etc., and in the general acces-

NOTES.

Personal.—Mr. W. M. Mordey has been on a visit to the United States.

Electric Culture.—A farmer, outside Madrid, drives his ploughs by electric motors.

Wath.—The question of electric lighting recently discussed at Wath (Yorks.) has been abandoned.

Morley.—A new town hall is to be erected at Morley, near Leeds. Someone ought to put in the electric light.

Cologne.—A large and important central station for supplying 18,000 lamps in Cologne is expected to be ready to start within the next month.

Utilising the Rhine Falls.—Capital to the extent of over £600,000 has already been subscribed to the scheme for utilising 16,000 h.p. from the Rhine to Rheinfelden.

Manchester Electrical School.—The electrical department of the Manchester Technical School, for the practical training of electrical engineers, will be ready for opening this winter.

Eastleigh.—The lighting of Eastleigh, Southampton, is to be carried out by 64 lamps. The gas company have the matter in hand, but the local electrical men might give the matter their attention.

Submarine Cables.—On the 27th August will be awarded at Paris (103, Rue de Grenelle) the public contract for the establishment of submarine cables (1) between Marseilles and Oran, and (2) between Marseilles and Tunis.

Nelson (Lancs.).—The Nelson Corporation have decided that should 100 tradespeople and others give a guarantee to take the electric light for three years, a scheme for electric lighting will be introduced under the provisional order of 1883.

Sale.—As will be seen elsewhere, a sale "by tender" will take place on August 19th and 20th of a bankrupt stock of electrical appliances, including lamps, wires, switches, instruments, and tools, by Mr. Fredk. Miller, 2, Serle-street, Lincoln's-inn-fields.

Cork.—The Cork Gas Consumers' Company recommend a dividend of 8 per cent., taking £813 from the reserve, which now stands at £11,638, or £578 less than last year. The directors contemplate seeking powers to supply electric light as well as gas.

Rochester Station.—The new works of the Rochester and Chatham Electric Lighting Company are satisfactorily proceeding. New boilers have been fixed, and the engine which was used in supplying the electric current to the Edinburgh Exhibition has been purchased.

River Lights.—The committee reported at the last meeting of the Southampton Town Council that the iron column for high light had been erected, and that the daily lighting and extinguishing of these lights would in future be attended to by the harbour master at a remuneration of £5 per annum.

Dover-Boulogne Cable.—The telegraph cable between Dover and Boulogne is to be relaid and a change made in the course it takes across the Channel, it having been deemed advisable, in consequence of the injury so frequently done to the cable at the base of the Shakespeare Cliff, to take the cable on to Folkestone.

Maidstone.—At a private meeting of the Maidstone Local Board, on Tuesday morning, the question of supplying the town by electricity was considered, and it was resolved to apply to the Board of Trade for a provisional order, and also if possible to put their rights into the hands of an electric lighting company.

Richmond.—The works for the weir and footbridge are now actively begun at Isleworth. If anything is to be done with the idea recently mentioned, of utilising the waters thus dammed back for the generation of electric power, no time should be lost in putting the subject before the Thames Conservancy in a practical form.

Llangollen.—A letter was read from Mr. Graesser, Argoed Hall, at the meeting of the Llangollen Highway Board, asking permission to place up electric wires over the road in Vroncysylltau. The Board agreed to the application on condition that the regulations of the Board of Trade in reference to such matters be complied with.

Beanfeast.—Messrs. Swinburne and Co.'s staff, workmen, and employés had their first annual beanfeast on Friday. They went in a steam launch from Staines to Windsor, where they had dinner. They then came down to Savoy's Weir for tea, and returned to Teddington in the evening, spending a pleasant day in spite of occasional showers.

Electric Woollen Mills.—An interesting item of news comes from Siebnen in Switzerland, where 1,000 h.p. is to be utilised from the River Aar. Of this 400 h.p. is to be utilised in Siebnen, and a new woollen factory to be driven electrically is to be erected by Messrs. Sulzer-Escher, of Zurich. The factory will give employment to 600 workmen.

East African Cables.—The German Government has decided to establish telegraph lines along the whole of the German East-African Coast. Three officials have left Berlin for Bagamoya, where they will, immediately after their arrival, commence the preliminary work in connection with the new lines. Bagamoya and Saadani will be first connected by wire.

More Exhibitions.—Exhibitionists are going to have a wide experience of the world in the next few years. This year Germany, next Palermo, then Chicago. After that Buda Pesth, for we see that it has been decided that an International Exhibition shall be held at Buda Pesth in 1895, the thousandth anniversary of the creation of Hungary as an independent state.

Blackpool.—Some of the Town Council of Blackpool want the electric light at once, others wish to see the scheme kept back six or eight months. The committee who have the matter in hand complained there was so much to do that electric lighting must wait, and was dubbed the "farce committee" for its pains. The report was sent back for reconsideration by a large majority.

Electric Pumps.—The Thomson-Houston Company make electric pumps for supply of water in buildings with motor and force pump, the motor having an automatic arrangement for stopping when the tank is full and starting just before it gets empty. Gould triplex pumps are used with a capacity of 100 gallons an hour, raised 30ft. high, run with a ½ h.p. motor off the town electric mains.

Barnsley.—The Park and Lighting Committee of the Barnsley Town Council reported on Tuesday that the borough surveyor laid before the committee a scheme and plan prepared by him for the supply of electricity to a smaller area than the one referred to in the Barnsley Electric Lighting Order, and the committee adjourned the consideration thereof until their next meeting.

Holborn.—A letter was read at the last meeting of the Holborn District Board from the City of London Electric Lighting Company, stating that they intended to apply to

the Board of Trade next December for a provisional order for lighting the Holborn district, and asking for an opportunity to discuss the matter with a committee of the Board. On the suggestion of the clerk, the matter was referred to the Committee of Works.

Old Students' Party.—A garden party of the Old Students' Association will take place in the grounds of Glebe Lodge, Champion-hill, on Saturday afternoon, September 5, from 3 to 7 p.m. Tickets (2s. 6d.) are to be had on application to the Hon. Sec., 88, Queen Victoria-street, and early application is requested. The meeting will be enlivened with tennis and music, and an enjoyable afternoon is to be expected.

New Cable to Germany.—The laying of a new cable between England and Germany has been completed. The cable was laid between Bacton (a town to the north of Lowestoft), in England, and Emden, in Germany. Herr von Stephan, Minister of Posts and Telegraphs, left Berlin for the latter town in order to attend the arrival of the English cableship "Faraday." The cable is 450 kilometres long, and will cost 2,000,000 marks (£100,000). This is the 12th cable connecting England and Germany.

Electric Heater.—Neat little pamphlets are issued of the Burton electric heater by the Burton Electric Company of Richmond, Virginia, and the Electric Merchandise Company, 11, Adams-street, Chicago. The heaters are now in use in a considerable number of cars at Joplin, Springfield, Indianapolis. The normal current is three amperes, and the extra cost of fuel is inappreciable at the station. The heaters are being applied on steam railways, and a large block of buildings has been fitted with them in the private apartments.

Electrical Standards.—Before the rising of Parliament last week a report was presented by the committee appointed by the Board of Trade to consider and report whether any, and, if so, what action should be taken by the Board under section 6 of the Weights and Measures Act, 1889, with the view of causing new denominations of standards for the measurement of electricity for use for trade to be made and duly verified. The report was accompanied by the minutes of proceedings and evidence, and appendices.

Dublin.—At the meeting of the Dublin Corporation last week, the Lord Mayor moved "that a meeting of the Council be held on the 14th September to consider and take action in reference to making application to the Board of Trade for a provisional order to replace the licence of 3rd May, 1889, empowering the Corporation to supply electricity for public purposes, and that of 24th June, 1890, to supply for private purposes, and to embrace both these licenses and their objects. The motion was seconded by Mr. Healy and adopted.

Newcastle.—Street lighting by electricity is making progress in Newcastle. One after another, our larger open spaces, says the *Newcastle Daily Chronicle*, are being illuminated by means of the arc light. The latest extension in this line is the illumination of the space at the top of Westgate Hill. The arc light fixed there has a brilliant effect on its surroundings. It caused quite a sensation on its first appearance last Saturday night. As compared with the electric light, gas is clearly out of the running as far as the lighting of large areas is concerned.

Transmission of Power in Scotland.—Electric transmission of power is growing—slowly, it is true; but the fact demonstrated and the utility felt, the practice will not linger long before becoming an everyday affair. We are pleased to notice an instance of the kind in Scotland. The Caledonian Mineral Oil Company, at the Lanark Town Council, submitted a proposal to erect across the White Lees, and asked for the Council's permission for the transmission of electric motors to drive a pumping engine at the loch. The permission was granted.

Electric Transmission Hand-book.—Mr. F. B. Badt has already issued several practical hand-books on electrical subjects, and the latest to hand is on electric transmission. Mr. Badt gives a considerable amount of information in a small space on the problems of transmission of power, calculating fall of voltage, efficiency, power of water, and kindred practical problems which the electrical engineer has to face. The hand-book has numerous illustrations and carefully compiled tables. It is published (price one dollar) by the Electrician Publishing Company, of Chicago.

Foretelling Storms.—The telephone, it is stated, can be used with great satisfaction for foretelling storms. By placing two iron bars at seven or eight yards distance from each other, and then connecting them on one side by a copper wire covered with rubber, and on the other side with a telephone, a storm can, so it is stated, be predicted at least 12 hours ahead through a sound heard in the receiver. As the storm advances the sound resembles the beating of hailstones against glass. Every flash of lightning produces a shock similar to that of a stone cast against the diaphragm of the telephone.

Ships' Compasses.—In reply to the remarks in Sir William Thomson's recent letter relating to concentric systems of wiring, Messrs. J. D. F. Andrews and Co. write "to respectfully state that Sir William has not been fully informed regarding our method of wiring, and we would state that we completely fulfil the conditions desired by Sir William by effectively insulating the outer conductor of our wire from the ship's hull in all parts where the compasses are at all likely to be influenced." They add that a more detailed description of their method of insulating the outer conductor was published the week following Sir William Thomson's letter.

York.—At the meeting of the York City Council on Monday, Alderman Agar moved the confirmation of the minutes of the Streets and Building Committee, which stated that the committee had taken into consideration the report of Mr. R. E. Crompton upon the proposed lighting of the city by electricity, which had been printed. The committee resolved that the Electric Lighting Sub-Committee be requested to visit places where the high and low tension system of lighting is in use, and report upon the working of the same. Considerable discussion ensued relating to various street improvements mentioned in the report, and ultimately the minutes were confirmed.

Sims' Electric Torpedo Boat.—A successful exhibition took place on Wednesday at Willeto Point, New York, of a new electric torpedo boat just completed for the Government. The requirements of the Government were a speed of 18 miles an hour, with a cable of 11,000ft. These were, however, exceeded, the boat making a speed of 20 miles an hour, and travelling 12,000ft. in six minutes and carrying a cable 2½ miles long. Mr. Sims, the inventor, conducted the test experiment, under the direction of the military and naval officers, and in presence of a number of invited guests representing foreign governments, all of whom declared the boat to be a complete success.

Bradford.—At the Bradford Town Council meeting on Tuesday, the minutes of the Finance Committee were adopted, including a resolution for the providing and fixing of apparatus for lighting the rooms of the Town Hall by

Alderman F. Priestman, chairman of the Gas ...icity Supply Committee, presented a statement ...he receipts and expenditure on the gas works during the half-year ending June 30 last. He said profits amounted to £6,249, against £6,010 for the ...ne period of last year. There had been an average increase in the price of coal of 1s. 5d. The gas sales had increased by £5,270. The total capital expended on the works was £582,871.

Medical Transformer.—An interesting application of transformers to medical practice is illustrated in the *Lancet* for August 8th. This consists of an apparatus for connection to the ordinary 100-volt alternating-current town mains, constructed by Mr. Schall, of 55, Wigmore-street, W. An 8-c.p. lamp burns over the transformer. Terminals are supplied to the coils, which transform down to six volts, giving a maximum current for cautery of 20 amperes, and a mimimum current of two amperes, and ½ volt can be obtained. Other terminals are supplied for surgical lamps, the power of which can be varied in the same way. The apparatus forms a neat and useful addition to advanced medical practice.

Ulverston.—The Board of Trade have written to the Ulverston Local Board intimating that they proposed to revoke the electric lighting order. The letter, said Mr. Tosh, had caused him extreme disappointment and almost pain. The Board took the trouble seven years ago to obtain a provisional order for electric lighting, and they had since done their best to keep their powers alive, but now they were curtly told by the Board of Trade that they intended to revoke the order. That meant that after spending £150 in getting the order seven years ago they now lost their powers because they had not used them. It was agreed to ask the Board of Trade to wait two months before deciding to revoke the order.

Fatal Fall of an Arc Lamp.—A little girl, Kate Wilkins, aged five years, the child of parents residing at St. John-street-road, Clerkenwell, was the victim of a peculiar accident on the 21st of July, and died last Saturday night at St. Bartholomew's Hospital. A large electric lamp, weighing 28lb., had been suspended outside the Agricultural Hall to advertise "Arcadia," and this, though held by a 38-strand wire, suddenly snapped and fell on the child, who happened to be passing with an elder sister. The child was struck down, and was taken at once in the ambulance waggon to the hospital, where it was found her skull was fractured. The operation of trepanning was performed, but with no good results.

Electric Mountain Railway.—The waterpower at Buochs, which is used by means of electric transmission of power to drive the funicular railway up the Burgenstock, is to be also made to supply an electric railway at Stauserhorn. This line is just begun, and will form a new rival to those up the Righi and Mont Pilatus. A force of 120 h.p. will be available from the dynamo and will be transmitted three miles. The line, which is two miles long, is divided into three sections of equal length, each section acting as a separate line with a motor of 50 h.p. available. The work is to be carried out similarly to the Burgenstock railway. MM. Bucher et Durrer, who are also the engineers to the new railway, have entrusted the electrical part of the work to Messrs. Cuénod, Sauetter, et Cie., of Geneva.

Cables v. Electric Tramcars.—Mr. John Paterson, Chairman of the Edinburgh Northern Tramways Company, speaking on Saturday at the half-yearly meeting, said it was interesting to note that the Birmingham Tramway Company, whose report was just published, stated that the expenditure on the part of their system worked by cables was 50 per cent. of the gross receipts, while the Electric Railway in London, which was originally intended to be worked as a cable system, showed that it was worked at a cost of 77 per cent. on the gross receipts. It was his opinion that the directors of the Electric Railway would regret that they had changed their original intention, and substituted electricity for cables. To give such a judgment within the first year is rash, to say the least of it. "He laughs best who laughs last," and cables are not carrying everything before them.

Crystal Palace Electrical Exhibition. — The directors of the Crystal Palace, in deference to the wish of the Electrical Trade Section of the London Chamber of Commerce, have decided to postpone the opening of the Electrical Exhibition from November, 1891, till the 1st of January, 1892, on which date the exhibition will be formally opened. We understand that the Chamber of Commerce proposed a further postponement, but the directors, anxious as they were to meet their views, could not agree to a later date than the 1st January without breaking faith with a large number of exhibitors who have applied for space, and who are now preparing their exhibits. It will be gratifying to intending exhibitors to learn that, with the view of promoting the success of the exhibition, the Chamber of Commerce have agreed to appoint a large technical committee to act with the directors of the Crystal Palace Company.

The Liverpool Overhead Railway.—The report of the directors states that considerable progress has been made with the works during the past half-year. The main structure is erected as far as the Collingwood Dock; the important opening bridge at the Stanley Dock is completed; and the accommodation works on the northern section are now in an advanced condition. The negotiations with the Corporation of Liverpool for the necessary deviations of the southern section have been concluded, and the directors have pleasure in acknowledging the liberal manner in which their proposals have been met. Sir W. Forwood, presiding at the annual meeting, stated that a contract for the equipment and working of the line by electricity had been made with the Electric Construction Corporation, Limited, of London and Wolverhampton. Two miles of the line have been completed within the last six months, and the railway will probably be opened next spring.

Aberdeen.—The question of utilising tidal power for electric light has again been raised, this time in Aberdeen, by a gentleman of the name of Mr. Evelyn Liardet. The proposal originated in a rather curious manner. The Duchess of Roxburgh, one of the ladies-in-waiting upon Her Majesty the Queen, seems, during her visits to Balmoral, to have gleaned that the Aberdeen authorities have been considering the question of introducing the electric light into the city, and, knowing this gentleman to be interested in such matters, she communicated to him the name of Lord Provost Stewart, and suggested that he might lay his electric lighting scheme before him. Accordingly Mr. Liardet forwarded a pamphlet to the Lord Provost, in which he described his scheme. He asked permission to examine the river Dee with the view of ascertaining whether or not it would be possible to drive electric machinery from the flow of water in the river. A discussion of the problem is arranged.

Southwark.—At the fortnightly meeting of the St. Saviour's Board of Works, held at the Board room, Emerson-street, Southwark, under the presidency of Mr. Baxter, the electric lighting question came under notice. The Paving and General Purposes Committee reported that they had considered the application of the Brush Electrical Engineering Company, Limited, for the consent of the Board to the transfer, pursuant to Section 61 of the

Southwark Electric Lighting Order, 1891, of that undertaking to a company to be formed under the title of the City of London Electric Lighting Company. The Committee now recommended that the Board's consent should be given unconditionally to the transfer of the undertaking, and also to the transfer to the new company of the wayleave agreement between the Board and the Brush Company and the memorandum thereto, dated respectively November 7, 1890, and April 27, 1891. The recommendation of the Committee was unanimously adopted.

Electric Boring.—A vast engineering work is being quietly carried on underneath the streets of Manchester in the reconstruction of the main drainage system. An interesting fact in relation to this scheme is that in the workings a new kind of boring machine has been introduced. This electric borer is the invention of Mr. Kellett, the contractor, and is said to mark a great advance upon other machines of the same kind. It is calculated to bore into the sandstone rock beneath Deansgate at the rate of ¼in. per minute, or 20ft. a day. It will be worked by electricity, with a dynamo of 12-h.p. The machine will consist of a drill and four arms for boring. Each arm is studded with ugly-looking teeth, all of which do their work in tearing and grinding up the rock. As the machine goes forward with its work, the material excavated falls into a bucket ready for removal. It is hoped that the machine will soon be in regular working order; and if it is as successful as is anticipated, similar machines will be placed in other places on the section.

British Association.—The following additional particulars are given of papers promised in Section A, besides the discussion on "Units and the Nomenclature": Prof. Ramsey, "On the Surface-tension of Ether at Different Temperatures"; Prof. W. Stroud, "Some Revolutionary Suggestions on the Nomenclature of Electrical and Mechanical Units"; Mr. W. H. Preece, "Further Researches on the Magnetic Quality of Different Steels on the Modes of Tempering"; Prof. S. P. Thompson (1), "On some Points connected with the Measurement of Lenses"; (2) "On some Experiments with Standard Cells"; Mr. G. H. Bryan, "Report on Researches Relative to the Second Law of Thermodynamics"; Dr. Johnstone Stoney, "On the Cause of Double Lines and of Equi-distant Satellites in the Spectra of Gases"; Prof. G. Forbes, "On the Secondary Compensation of Thermometers"; Mr. J. Swinburne, "The Causes of Variation of Standard Cells"; Mr. F. T. Trenton, "Magnetic Experiments Made in Connection with the Determination of the Rate of Propagation of Magnetisation in Iron."

Electric Trams for Handsworth.—A meeting of the Handsworth Local Board was held on Wednesday, under the presidency of Mr. David Rose. Mr. J. J. Hughes presented the Highway Committee's report, which recommended the Board to sanction the use of steam by the Central Tramways Company for a further period of 12 months on the Birchfield route. Mr. H. Hossell, in seconding the report, said he hoped it was the last time they would have to sanction the use of steam. The company had electric power on the Bristol-road route, and he considered they should insist on the same system being adopted on the Birchfield line. Mr. Hughes said there was no doubt the company had a very serious knock back by the telephone company. He hoped, however, the tram company would speedily surmount the difficulty. Mr. Hossell was of opinion that in the interest of the parish they should take the matter up strongly. The property on the Birchfield route had deteriorated in value 25 per cent. through the abominal [illegible] e of steam trams. They shoul[illegible] their p[illegible] ctricity or some other motive power, in order to do away with the nuisance. The report was adopted.

Manchester.—The Electric Lighting Sub-Committee appointed by the Gas Committee of the City Council, we learn from the Manchester papers, have had under their consideration the reports of several consulting engineers as to the proposed installation of the electric light in Manchester. They have decided to recommend the appointment of an electrical engineer, who will advise as to the best system of lighting to be adopted, and will also superintend the operations of the contractor whose tender may be accepted for the work. This gentleman will receive a commission on the cost of the scheme, as is customary in the case of architects. The sub-committee recommend that the "low pressure" shall be adopted, but further details of the scheme will be arrived at after the engineer has been appointed. It is proposed to confine the operations of the committee entirely to a street installation. No apparatus in the interior of houses will be supplied, and those who desire to take advantage of the installation will have to execute their own connections. In this respect the committee's scheme differs materially from the ordinary commercial operations of electric lighting companies.

Reduction in Telephone Rentals.—The Western Counties and South Wales Telephone Company announce important reductions in rentals and an increase of area at the reduced rates for connections to their local telephone exchange systems commencing September 1. Each business or professional connection for lines within one mile radius of the Company's exchange will be charged the following rates: £9 per annum on seven years' agreement; £10 per annum on four years, and £11 for a yearly agreement. Private residences, without business or professional practice, may now be connected to the exchange at rentals varying from £5 to £8 per annum according to distance, not exceeding one mile, from the nearest exchange. Another important feature in connection with the company's rates is that there will be in future no further liability on the part of the renter, as the charges are inclusive of the cost of construction of the lines, erection of instruments, and maintenance of the whole in proper working condition. The directors are prepared to convert the unexpired period of existing subscribers' agreements to the new rates for either of the three periods, provided that the period is not less than that remaining unexpired on the existing contract.

Electric Motors in France.—At Vitry, in France, is a series of wine cellars belonging to the Compagnie L'Orléans. In this are a number of machines requiring power to drive, and the company recently decided to institute a distribution of power by electricity. A Rechniewski compound machine was installed, driven by the works engine. It gives a current of 82·5 amperes at 170 volts for 1,200 revolutions, used partly for power and partly for the entire lighting of the works. The current is received by two motors furnished with resistance stands. The rest of the apparatus is so arranged that whether the motors work or not there is no influence upon the regularity of the light. The lighting is produced by seven arc lamps for eight amperes in the courtyards, and three arcs of six amperes inside; also 10 incandescent lamps of 200-c.p. and 50 of 16-c.p. in the workrooms and stores. Besides this, the same company has installed a complete system of distribution of power in their works at Paris, where it is also used to drive a large drum for washing linen. The power is taken from the engine used to drive a sawmill. An Edison dynamo, 20 amperes and 110 volts compound wound drives a motor with special winding; this is used with gearing to turn the machinery at 75 revolutions a minute, constant speed, notwith-

anding what power is required. The conductor used copper wire of 10 square millimetres, insulated and in in casing where it passes into the interior.

Belfast.—The report of the Gas and Electric Lighting Committee was before the quarterly meeting of the Belfast Corporation last week. The Mayor said the council had appointed a committee some time ago to visit London for the purpose of visiting the installations of the electric light there, not for the purpose of deciding between gas and electric lighting, but to investigate the subject as to the best means of applying the electric light to the district to be lighted in the City of Belfast under the provisional order for the purpose. Following that up, their committee went to a number of stations: Paddington, the Great Western Railway Company's station in the same district, Kensington (High-street), Notting Hill, Brompton, Charterhouse-square, Deptford, and the Westinghouse Company's installation. They would see, therefore, that the committee had not been neglecting their duty. There were some difficulties in the way of that committee reporting fully at present. It was true that they found that the electric light was in practical operation in London, but, at the same time, they were not able to get proper data as to the cost in order to lay a full report before them. Further enquiries were being made in order to complete the report, which would be laid in a few days before them. There was a tendency in the public mind to imagine that because they were going to light a small district of Belfast by electricity that, therefore, all progress in the gas works should be stopped. No greater mistake could be made. The experience of large cities such as Manchester, Leeds, and other places, was that, although they had the electric light in full operation, the consumption of gas was actually increasing every day. He thought it was well for the citizens of Belfast that they should get it out of their minds that for the present at least the electric light was likely to be a successful rival of gas. On the contrary, there existed an urgent necessity for the extension of their present gas works, and they would have to take into consideration, at an early day, how they were going to extend those gas works. He thought they ran a great risk in going through another winter without increase of light. The report, which stated the committee hoped to report further in August, was adopted.

Birmingham Tramways.—At the annual meeting of the Birmingham Central Tramways Company on Tuesday, the chairman (Mr Joseph Ebb Smith) made the following references to electric traction: They were bound, he said, to look forward to the future, and they knew that the abolition of steam traffic was but a question of time. It was useless to blink the fact that in future another form of traction would very probably obtain. But during the whole tenure of his office he had most scrupulously abstained from anything approaching to prophecy, and he bade them take this comfort home with them—that, having regard to the character of the main lines of the city, and having regard to the accounts of the cable department which were now before them, when the time arrived for the reconstruction of the form of traction haulage of the company the present shareholders need not fear or doubt their own position. He did not advocate any rash or sudden change. They had had a period of strain in the past; they asked for the consideration of the local authority and those in power during the period of rest and experiment, and during which they might obtain something like certainty with regard to the results of working any other systems. Whenever it did come, it would be, in his opinion, an advance from solidity of position to prosperity, and not a case of injury to the ordinary shareholder, by reason of the transformation. As to the cost of fuel during the past year, he said it would not be without interest to them if he quoted the comparative increases in the cost of the fuel during the last four years. The fuel which cost 10s. 5d. per ton in 1887 had risen step by step to more than 17s. in 1890-91. Fortunately for them the increase in the cost of fuel had been commensurate with prosperity, increased traffic, and increased profits. In answer to Mr. Whitfield as to the cost of the electric tramway in Bristol-road, the Chairman replied that, roughly speaking, the cost was about £30,000. Mr. Whitfield: What did the cable tramway cost? The Chairman said that, roughly speaking, the cost was about 50 or 60 per cent. more than the electric tramway. Mr. Whitfield: That is about £50,000. The Chairman said he was speaking of the cost of construction, but they must bear in mind the question of working, which was a more intricate subject. The motion for the adoption of the report (which we gave last week) was carried unanimously.

Gaiety Theatre, Dublin.—Ireland possesses in the Gaiety Theatre at Dublin what is described as one of the best appointed theatres in the three kingdoms. Mr. Michael Gunn has recently determined to carry out a very extensive series of improvements, amongst which the complete fitting of the electric light stood foremost. This has been very successfully carried out within four weeks' time, under the supervision of Mr. Harry South, who was engaged by Mr. Gunn for that purpose, and several of his special stage appliances were introduced. The interior is hung with handsome electroliers, fitted with delicately tinted glass flower bulbs. The construction of the entire and complex plant was entrusted to the Electrical Engineering Company of Ireland, and was carried out under their chief engineer, Mr. Porte. Behind the stage entrance is the engine-house, where two Otto gas engines (14-h.p. each) have been erected by Messrs. Crossley and Co., of Manchester. These engines have been specially designed for electric lighting purposes, and are the first of their kind that have been sent to Ireland. They drive two compound wound dynamos built by Messrs. Laurence and Scott, of Norwich. Both engines and dynamos were specially constructed for this contract, and either set is capable of lighting all the lamps that will be in use at one time. The dynamos are driven by cotton ropes. The engine-house also contains very complete switching arrangements, which enable the load to be thrown at an instant's notice from one engine and dynamo to the other without a break, not a flicker being apparent in the 250 lamps of the installation. The roof above presents a curious appearance. It is covered by a network of wires communicating with a switch-board at the side of the stage, which is provided with a series of levers governing the entire lighting system of the house, and with indicators which show the pressure and quantity of the current. From this point the lights employed for all stage effects are controlled. Resistances have been arranged so that it is possible to lower the lamps in different degrees from full power to a mere glow, and the turn of a handle upon a circular plate reduces the number of footlights, so that any conceivable quality of illumination is producible at will. To this part of the installation Mr. Gunn, who is himself an electrician of some experience in connection with the lighting of the Savoy, has given particular attention, and the system is considered as perfect as it is possible for modern scientific skill to render it. The whole of the work reflects the highest credit upon those engaged in it. The machinery had to be built, the switching arrangements designed and made, and the entire plant perfectly fitted in three weeks after the order was received. All hands worked night and day and no labour was spared. The trial on Saturday was a great success.

ON A TEST OF EWING AND MACGREGOR'S METHOD OF MEASURING THE ELECTRICAL RESISTANCE OF ELECTROLYTES.*

BY PROF. J. G. MACGREGOR, D.SC., DALHOUSIE COLLEGE, HALIFAX, N.S.

Some time ago Prof. Ewing and I published a paper† on the electrical conductivity of certain saline solutions, in which we gave the results of observations of the resistance of electrolytes by a very simple method, requiring no elaborate apparatus, and capable, therefore, of being applied at a moment's notice in any laboratory provided with the usual outfit of galvanometers and resistance coils. Shortly after the publication of our paper it was sharply criticised by Prof. Beetz,‡ who endeavoured to show that the method was defective and the results untrustworthy. In reply,§ I showed that he had completely misunderstood our method, and that the data on which he based his condemnation of our results were insufficient. Subsequently, Prof. F. Kohlrausch ‖ subjected our method to criticism, expressing the opinion that the kind of galvanometer which it demanded was incapable of construction, and pointing out that his results differed from ours, in cases in which we had experimented with the same salts, by various amounts ranging from 0 to 12 per cent. I have not the slightest doubt that Prof. Kohlrausch's results are far more accurate than ours. For apart from the undoubted trustworthiness of his method, he is an experimenter whose ability and experience have long ago been placed beyond question, whereas at the time of the publication of our paper Prof. Ewing and I were both students, and possessed little of the power of avoiding errors which only experience can develop. But while it may be regarded as practically certain that our results were by no means exact, it has always seemed to me to be doubtful if Prof. Kohlrausch's opinion, that a galvanometer such as our method requires was incapable of construction, was well based. And as our method is simple, and if trustworthy would be very convenient for ordinary laboratory work, I have thought it well to test it.

As the method refered to has been apparently misunderstood and certainly inaccurately described even by such exact authors as Prof. G. Wiedemann¶ and Prof. Chrystal**, it seems probable that our description of it must have been defective. It may therefore be well for me to describe it anew before referring to the test which I have recently applied to it.

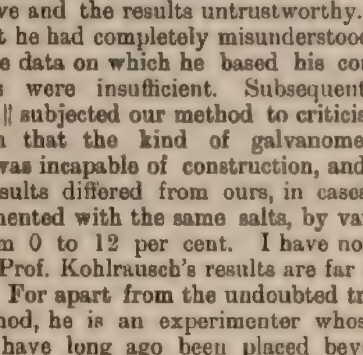

Fig. 1.

Let A B, B C, C D, D A, B D, and A C, Fig. 1, be six metallic conductors with similarly named ends connected, of which A C contains a voltaic cell or battery of E.M.F., E, so inserted as to send a current, say, from A to C through B and D. Then, as is well known, it may be shown by means of Kirchhoff's equations that if G is the strength of the current flowing in B D, and r_1, r_2, r_3, r_4, g and b the resistances of A B, B C, C D, D A, B D, and A C (including that of the battery), respectively, we have

$$G = E(r_2 r_1 - r_1 r_3) / bg(r_1 + r_2 + r_3 + r_4) + b(r_1 + \ldots (r_2 + r_3) + g(r_1 + r_2)(r_3 + r_4) + r_1 r_3 (r_2 + r_4) + r_3 r_4 (r_1 + \ldots$$

It follows that G and $r_2 r_4 - r_1 r_3$ must vanish together, upon this result the measurment of the resistance of metallic conductors by means of Wheatstone's bridge depends. A key is inserted in A C so that the current may be allowed to flow through the system of conductors as often as may be desired. A galvanoscope is inserted in B D so as to indicate whether or not a current is flowing through that branch. The conductor whose resistance is to be determined is made one of the "arms" of the bridge, A B, B C, C D, or D A, and the resistances of one or more of the other arms are then adjusted until on sending a current through the system, the galvanoscope gives no indication. Since in that case $r_2 r_4 - r_1 r_3 = 0$, and three of these four quantities are known, the fourth may at once be determined.

The determination of the resistance of an electrolyte is not in general so simple, because it can be connected with the other conductors as one of the arms of the bridge, only by means of electrodes. These electrodes must be of a substance on which the electrolyte has no chemical action, and in most cases should therefore be of platinum. But no sooner does the current pass through an electrolytic cell with platinum electrodes than they become polarised, and the electrolytic cell becomes in fact a voltaic cell, with an E.M.F. which increases from the value zero to a certain maximum value, and which tends to send a current in the direction opposite to that of the polarising current.

In one very important case, that of an electrolytic cell containing solution of zinc sulphate of proper strength with amalgamated zinc electrodes, a current produces no polarisation, and as my experiments* have shown that there is also in this case no appreciable transition resistance, the resistance of solutions of this salt may be determined as exactly and as simply, and by the same method, as that of metallic conductors.

In general, however, platinum electrodes must be used, and if an electrolytic cell with these electrodes be inserted in one of the arms (say C D) of the bridge, we have, as soon as the current begins to flow, an opposing E.M.F. in C D, and therefore the expression for G given above no longer applies. Let e be the value of this opposing E.M.F. due to polarisation, at any given instant after the current has begun to flow, r_3 being the resistance of the electrolytic cell and the wires by which it is connected to C and D. Then it is easy, by writing down Kirchoff's equations, to show that

$$G = E(r_2 r_4 - r_1 r_3) - e[b(r_1 + r_4) + r_4(r_1 + r_2)] / bg(r_1 + r_2 + r_3 + r_4) + b(r_1 + r_4)(r_2 + r_3) + g(r_1 + r_2)(r_3 + r_4) + r_1 r_3 (r_2 + r_4) + r_2 r_4 (r_1 + r_3).$$

The second factor of the second term of the numerator and the denominator, of this expression, are essentially positive quantities, and E and e change sign together. Suppose now that the resistances of the arms of the bridge are so adjusted that $r_2 r_4 - r_1 r_3$ has a finite positive value, then at the instant at which the current begins to flow through the system, e being zero, G has a positive or negative value according to the sign of E. As time goes on e increases, and therefore G diminishes numerically. After a certain time, provided that the resistances of the arms and the maximum value of e are such that we may have

$$e[b(r_1 + r_4) + r_4(r_1 + r_2)] > E(r_2 r_4 - r_1 r_3),$$

G becomes zero, and ever after that G will be negative if it was positive before, and positive if it was negative before. In short, provided $r_2 r_4 - r_1 r_3$ has a positive value, the current through B D flows first in one direction with gradually diminishing strength, and then in the opposite direction.

With a battery of given E.M.F., the greater the value of $r_2 r_4 - r_1 r_3$—*i.e.*, the farther the arms of the bridge are from the adjustment, which, for $e = 0$, would give no current in B D, the longer is the time in which G has the same sign as at the instant at which the current begins to flow. If this value be made small, that time becomes small; and if the resistances be so adjusted that $r_2 r_4 - r_1 r_3 = 0$, the

through B D flows at the outset in the same on as subsequently.

ow we had a galvanoscope which would respond aneously to any change in the current flowing h it, so that at any instant it would indicate the on of the current flowing through it at that instant, t were inserted in B D, it would be possible to make et determination of the resistance, r_3, of the electro- ell. It would only be necessary first to get the ces of the arms so adjusted that on passing the the galvanoscope would give a double deflection ing a current first in one direction and then in the and next to change step by step the adjustment of istances of the arms until on passing the current the on would just cease to be double. For the adjust- f resistances with which the deflection of such an nent would just cease to be double is, as we have ach that $r_2 r_4 - r_1 r_3 = 0$. A galvanometer of the y form, but with a mirror and magnet of indefinitely moment of inertia, hung by a fibre offering no resist- torsion would form an instrument of the kind d. But such a galvanometer is, of course, ideal.

an actual galvanometer in the bridge, having a and mirror with finite moment of inertia, no able motion of the magnet can be produced until rent has acted for a certain time. Obviously, there- we start with such an adjustment of the resistances arms, that this instrument gives, on the passing of rent, a double deflection, and if we gradually change justment until the double deflection just vanishes, be sure that $r_2 r_4 - r_1 r_3$ has still a positive value. magnet of small moment of inertia it may be small, will still have a value. And if the vanishing of the ness of the deflection were the only observation could be made, it might not be possible with any and mirror yet manufactured to make this value nough to be neglected. But it will be obvious that, resistances of the arms have been so adjusted that sing the current the deflection has just ceased to ble, then during the time which elapses before an able motion of the magnet occurs, it has first received pulse in one direction and subsequently another e in the other direction, and the motion in this on is due to the resultant of these. Hence the magnet t begin to move immediately after the current begins , but for a certain time remains at rest. And this the case so long as $r_2 r_4 - r_1 r_3$ has a positive value. even an ordinary galvanometer which, when $r_1 r_3$ is small, is not sensitive enough to give a double on, will exhibit a hesitation at the beginning of its deflection. As the value of this quantity becomes and smaller the hesitation diminishes, and the diffi- f observing it of course increases. But, obviously, if ust the resistances until there is not only no double on but also no hesitation, we get $r_2 r_4 - r_1 r_3$ more equal to zero.

ther or not with any given galvanometer we are d in assuming $r_2 r_4 - r_1 r_3$ to be practically zero when justment of resistances is such that the hesitation referred to can just not be observed, can only be ined by experiment. The mirror (with magnet) of strument which Ewing and I used weighed 0·03 e, and its diameter was 8 mm. Its moment of therefore, was exceedingly small, so small that we ered ourselves justified in making this assumption.

ill be obvious from the above, that it is not necessary, lying the method under consideration, that the ts, which are passed through the cell to test the nent of the resistances in the arms of the bridge, be momentary. So far as any one observation is ned the current may be allowed to pass for any of time. But as the next succeeding observation be made until the polarisation produced by the has died away, and as the passage of the current s the constitution of the liquid in the cell, it is for easons desirable that the current should be allowed for as short times as possible.

h regard to the practical working of the method it e noted that it is difficult to obtain platinum plates when used as electrodes, do not themselves constitute a voltaic cell. In the experiments which I have recently made I found it quite impossible. My electrolytic cells were in all cases found to be voltaic cells of small and practically (apart from polarisation) constant E.M.F. If we call e' the E.M.F. of the electrolytic cell due to the electrical difference of the electrodes, it is easy to show that we have for the strength of current through the galvanometer,

$$G = E\,(r_2 r_4 - r_1 r_3) - (e \pm e')\,[b\,(r_1 + r_4) + r_4\,(r_1 + r_2)] \,/\, b\,g\,(r_1 + r_2 + r_3 + r_4) + b\,(r_1 + r_4)\,(r_2 + r_3) + g\,(r_1 + r_2)\,(r_3 + r_4) + r_1 r_3\,(r_2 + r_4) + r_2 r_4\,(r_1 + r_3).$$

If now $r_2 r_4 - r_1 r_3 = 0$, then, at the instant at which the current begins to flow, e being zero, we have, if for the denominator of the above expression we write d,

$$G = \pm \frac{e'[b\,(r_1 + r_4) + r_4\,(r_1 + r_3)]}{d},$$

$$= \pm \frac{e' r_1}{g\,(r_1 + r_2) + r_2\,(r_1 + r_4)},$$

which is independent both of E and of b. If, therefore, we had a galvanometer with a mirror of indefinitely small moment of inertia, we might proceed exactly as we would if e' had the value zero. With an actual galvanometer, however, it is obvious that the adjustment of the arms which will just give no double deflection, or no hesitation at the beginning of the single deflection, will not be exactly the same as it would if the electrolytic cell were not behaving as a voltaic cell, for the first appreciable motion is due to the integral effect of the superposed currents due to three sources of E.M.F. In such cases, however, it is comparatively easy (though it increases the time necessary to make a determination of resistance) to produce, before each step in the adjustment of the arms, a polarisation in the cell, whose E.M.F. is equal to e' and of opposite sign. For this purpose a current is sent through the cell in the proper direction long enough to produce more than the required polarisation. As this polarisation slowly dies away, there will be a short time during which the E.M.F. due to the polarisation will just neutralise e', and in that short time the adjustment of the arms may be tested without error due to e'.

It is obviously desirable that in applying this method, the E.M.F. due to the polarisation of the electrodes should be as small as possible; and the satisfaction of this condition requires (1) that the electrodes should be as large, and (2) that the current through the electrolyte should be as weak as possible.

The size of the electrodes will in general be determined by the cell to be used. If we wish to determine the specific resistance of a liquid, of which we have a large quantity, we may take them as large as we please. But, if we wish to determine the resistance of a given electrolytic cell, their area may require to be small. In that case it may be necessary to platinise them after the manner of Kohlrausch* and Grotrian. Whether or not platinising may be necessary depends upon the sensitiveness of the galvanometer at our disposal, and can be determined only by experiment.

If the polarisation produced in the electrolytic cell be found to be too great to give good results, the current through it may, of course, be weakened either by diminishing the E.M.F. or increasing the resistance of the battery used, or by proper adjustment of the resistances in the arms of the bridge.

The adoption of any of these means of reducing the polarisation, however, will, in general, diminish the sensitiveness of the bridge; and thus a happy mean must be struck between the conditions which must be satisfied to keep down polarisation, and those which must be satisfied to keep up sensitiveness. This happy mean can be selected in any given case only by experiment. We can recognise the fact that we have hit it by the degree of facility with which we can distinguish between the adjustment of the arms giving an obvious hesitation at the beginning of the single deflection, and the adjustment giving obviously no hesitation. If it requires a considerable change in the adjustment of the arms to produce the change from obvious hesitation to obviously no hesitation, the current

* "Pogg. Ann.," Bd. cliv (1875) s. 7.

through the cell may be known to be too strong, and must be reduced in such a way as to diminish the sensitiveness of the bridge as little as possible. I have found more difficulty in securing sufficiently low polarisation in the electrolytic cell when its resistance was low than when it was high. But this was obviously due to the fact that my box of coils was a very small one and admitted of but very slight change in the resistances of two of the arms of the bridge. With adequate appliances I see no reason why the method should not be as readily applicable to cells of low as to cells of high resistance.*

It will be obvious that the resistances given by this method must be too high, for when hesitation can no longer be observed we have the arms so adjusted that

$$r_2 r_4 - r_1 r_3 = k,$$

where k, though small, is a positive quantity. Hence, the resistance of the cell,

$$r_3 = \frac{r_2 r_4 - k}{r_1},$$

and is therefore really less than it seems to be when we assume k to be zero.

(To be continued.)

IS "EARTH" OF ANY VALUE AS THE TERMINATION OF A LIGHTNING CONDUCTOR?

BY SYDNEY F. WALKER.

Students of Dr. Lodge's researches and lectures on the subject of lightning and its efficient discharge will remember that one of the great points he first made in his able attack upon the old methods was, that "earth" was of no value whatever. The utmost that he would allow after the discussion at the B.A. meeting at Bath was that "earth" might not be a bad thing. In one of his first lectures on the subject he pithily summed up the argument thus: "Why need lightning make any trouble over a few feet or a few yards of earth, when it has already come through several miles of air." It must be confessed that, put in this way, the argument looks convincing. It has been the writer's opinion, however, from the first that "earth" played a very important part indeed in the matter of the effective discharge of a thundercloud, but that the whole thing turned upon the question what is "earth" for a lightning flash? In a previous article he has endeavoured to show that proper "earth" is by no means a simple matter, even when we know to a very much larger extent what we are dealing with than we do in the case of a highly-charged cloud discharging to the buildings or other objects below it. For the first time in his 17 years' experience the writer has felt our pressing want of knowledge of what electricity is. When we are sending an electric current from London to Manchester to work a telegraph apparatus there we know that, whatever that current may be, and whether the conductor be a metallic wire, as we view it, or an elongated elastic bag, as Dr. Lodge's latest theory of electricity would picture it, some path having the same properties as the wire by which the current went to Manchester must be provided to bring the same current back to London, or the apparatus at Manchester will not work. The current may go round by Glasgow, Douglas, even New York, or by any route that nature provides, but come back it must, subject only to the conditions of Ohm's law. But with a thundercloud apparently there is no such necessary connection. We see the cloud, dark and ominous—in this country, at any rate—gathering overhead; we see the flash, we hear the roar, and sometimes we find that some chimney has been struck and thrown down; sometimes a monarch of the forest has been riven in two, leaving a blackened trunk in place of the previously healthy tree; sometimes, again, an innocent sheep, or an ox, or even a man receives the flash and may fall dead. Apparently there is no connection here with "earth" or "ground" as we understand it in connection with the distribu[illegible] electrical currents for useful purposes. The vaga[illegible]ng—how it strips a man's fo[illegible]g the [illegible] it prefers to [illegible] *through* [illegible] no wa[illegible] own the c[illegible]

ductor provided for it, etc.—will be fully dealt [illegible] another place. The question now proposed to be discu[illegible] merely this one of what effect "earth" has on the dis[illegible] Seeing the apparently uniform behaviour of lightning [illegible] idea of the earlier electricians that all that was required [illegible] to provide a safe path to a safe earth, is hardly [illegible] wondered at. Apparently the lightning flash always [illegible] "earth," though it may be by way of the body of an [illegible] or the mass of a building, so that all that should be [illegible] should be to give it plenty of room in transit and a [illegible] able bed on its arrival. As the writer pointed out [illegible] discussion on the subject at Bath, the problem invol[illegible] the safe discharge of a thundercloud is closely an[illegible] to that involved in dealing with the huge reservoirs [illegible] supply our large towns with water. If the wat[illegible] allowed to overcome its dam, it pours down the [illegible] carrying all before it. If it is made to dribble [illegible] it not only does no harm, but is useful. A light[illegible] conductor may be said to fill the same office that a ch[illegible] made for the water leading directly to the sea wou[illegible] it were possible and so arranged that the whole of [illegible] water in the reservoir could be allowed to run harml[illegible] down this channel immediately there were signs of [illegible] dam being likely to give way.

The idea of discharging a thundercloud is taken en[illegible] from the old idea mentioned in the previous article on [illegible] subject—viz., that Mother Earth is a reservoir of in[illegible] capacity for electricity, just as she is for water. Imm[illegible]diately this idea is given up the apparent use of "earth" [illegible] gone. So far as can be seen, there is no return [illegible] necessary when a discharge from a cloud kills a ma[illegible] shatters a chimney. Lightning surely knows its [illegible] way about, and if it does not require "earth" in [illegible] case, why provide "earth" at all? Further, Dr. Lo[illegible] professes to have discovered cases in which buildings [illegible] been struck which were properly protected by light[illegible] conductors of the most approved modern type. On [illegible] point, however, there is a difference between Dr. L[illegible] and those who uphold the old form of lightning condu[illegible] At the Bath meeting Dr. Lodge was challenged to giv[illegible] instance where a building had been struck when fitted [illegible] a conductor properly fixed, properly pointed, and prope[illegible] "earthed."

In his reply, Dr. Lodge palpably begged the que[illegible] "Whenever a building was struck," he said, "elec[illegible] engineers always declared that the conductor, if it had [illegible] was not a proper one, or was not properly 'earthe[illegible]' Though this answer practically admits defeat on [illegible] professor's part, it is hardly satisfactory to allow [illegible] matter to rest there. We want to know why these ca[illegible] occur, and though Dr. Lodge may not be able logically [illegible] defend his position, we are still very much obliged to h[illegible] for raising the whole question, and for throwing the li[illegible] he has upon it. This action has taken the whole thing [illegible] of the old rut in which it had laid for so long. Th[illegible] question comes back then to this, what office are we to [illegible] that earth now fills with our enlightened views of [illegible]ductors, and of the part that earth plays as a conductor[illegible] Is it correct, as Dr. Lodge asserts, that it performs [illegible] useful office; that it, perhaps, leads the lightning discha[illegible] into places where it may do real damage that wou[illegible] otherwise be avoided? Unfortunately, the conduct[illegible] and even its earth terminal, do lead lightning curre[illegible] often into places where damage results. In th[illegible] writer's opinion, however, earth does perform a usef[illegible] office in connection with the discharge of lightning, even [illegible] view of our advanced knowledge of the subject; and h[illegible] believes that the solution of the apparent paradox will b[illegible] found to be the same as that of "Tam's" difficulty with h[illegible] frictional machine, that was referred to in the previous artic[illegible] It will be remembered that, according to the writer's vie[illegible] "Tam's" failure was due to the exceedingly dry state [illegible] the atmosphere, during that particular season, having [illegible] increased the resistance of the connection between one p[illegible] of his frictional machine, the earthed pole, and the oth[illegible] side of the inductive circuit—viz., the walls of the room, etc. But if this is correct—and if it is not, the writer would be very glad to hear other views on the matter—does it not apply equally to a thundercloud? What is [illegible] [illegible]undercloud but a huge generator of electricity? [illegible]

nal or hydro-electrical machine on an enormous scale? the reason, too, that no discharges take place under e conditions, while they are frequent under other ions, merely that the resistance of the circuit in the se is so great that no discharge can take place, while other it has been reduced to within such limits that k can pass at some point? Consider the conditions e closer. When do lightning discharges usually occur? not when the atmosphere is full of moisture, drawn the ground below by the intense heat of summer? oes not the same cause tend to reduce the resistance ther way—viz., by lessening the distance between the and the earth, the heavy mass of vapour tending to pull n? Next consider what happens when a cloud becomes ed. The writer is afraid that, with all due respect Lodge, he must leave the elastic bags to take care of elves, and revert to the reasoning that is common in branches of electrical science. If a cloud becomes ed then, work is done upon it. It is capable of doing in return, and will do that work if favourable condi- arise. Further, if a cloud, or one part of a cloud, nes charged, say positively, it is implied that a nega- harge exists elsewhere. Would it not be better to is fact in the practical form in which electrical engi- are accustomed to deal with phenomena comprising the on or the expenditure of electrical energy, and say that M.F. is created between certain parts of the cloud and objects; probably other portions of its own mass being led in the phenomena. If the E.M.F. existing between t in the cloud and any point in surrounding objects be ent to overcome the electrical resistance opposed to it, current passes, varying in form according to the con- s present; such, for instance, as the rate at which the ing resistance is lowered, etc. Probably minute, ess, possibly health-giving electric currents are always g between cloud and cloud, and from individual to the earth. But in order that a current shall pass, ow that the whole resistance of the circuit must be s will allow of its passage, not that of one small n. It is well known that a shock of high voltage e taken from a frictional or induction machine without r, where the same voltage applied to the body from a no used for electric lighting would cause instant death. xplanation is, that though the resistance of the body same in the two cases, or nearly so, that of the other ns of the circuit—in particular the internal resistance machine itself—is enormously greater in the one case in the other, so great, in fact, as to absorb or use up a portion of the E.M.F. generated before any current s the external circuit. Electrical engineers know what it to have a dynamo or a battery whose internal resistance of proportion to that of the apparatus to be worked. for instance, a battery of 10 cells, each having an al resistance of 10 ohms, while that of the line and atus outside is only one ohm. As we know, we prac- get no current from such a combination; and we d get none from it if we had 100 or 1,000 similar And so it is with the Holtz machine, and with the ercloud.

t what is the circuit which governs the discharge of undercloud? It is assumed that the cloud acts only e plate of a condenser or Leyden jar, the earth ng the other; that the cloud, once charged, may be d upon as cut off—just as one may charge a Leyden d have done with it. Obviously, this is an incorrect iption; and it is only fair to Dr. Lodge to mention in his experiments he does not appear to take this It is evident, of course, that a charged cloud fills ame, or nearly the same, position with regard to nding objects that a frictional machine does. It is erator, and at the same time it forms one side of the nser, of which the earth and other clouds form the But it must not be forgotten that while there is *luctive* connection—if it may be so termed—between oud and surrounding bodies, there is also a *conductive* ction, and that the office of the inductive connection y to determine the positions of strains, or of E.M.F's. nsider, again, what happens when a charged cloud over a particular portion of the earth's surface. bly, during its motion, its charge is being increased by friction with the atmosphere. We know, also, that assuming one extremity of the cloud to be charged positively, the earth and other objects near will be charged negatively. At any rate, there is an E.M.F. existent between them, similar to that existing, say, between the terminals of a dynamo; and if we examine surrounding objects, we shall find that they display characteristics which we associate with a charge of a certain name, opposite in character to that of the inducing body, the cloud. But, assuming this to be correct, how did the charge reach the objects named? We know, for instance, that the nearer objects will be more highly charged than those more remote, and we know that this charge means—unfortunately this is where we want a little more light. At any rate, we do know that the induced charge, whether positive or negative, has only been allowed by conduction from surrounding objects. That is to say, when, in obedience to the inducing force exercised by a highly-charged thundercloud, the top of a factory chimney, say, becomes positively electrified, or there appears a difference of potential between it and not only the cloud, but surrounding bodies on its own side of the condenser dielectric, this state has been arrived at by means of electric currents passing from these surrounding bodies, and possibly from the cloud itself, to the chimney-top. When also, owing either to the departure of the cloud, or to its whole or partial discharge, the strain is relieved at that particular point—in other words, the difference of potential is lowered, and a redistribution takes place—this also will be by means of currents of electricity, as we understand them. Further, when a discharge between a thundercloud and an object attached to earth takes place, be that object a mill chimney, a Royal palace, an oak, or an animal, the discharge, be it harmless or disastrous, must be by means of one or more electric currents, taking the term in the sense in which we now understand it.

The point whether a Leyden jar discharge, or a lightning discharge, be by continuous or oscillatory currents, in the writer's opinion hardly affects the question. If the discharge is oscillatory, it will be so because under certain conditions, an opposing E.M.F. is created in the process of first discharge, which in turn delivers its current along the path or paths open to it. Nor can the question whether a conductor of large sectional area offers the resistance that Ohm's law would dictate, or offers a higher apparent resistance owing to induction within itself, affect the argument. It may at once be acknowledged that a copper rod, or rope, or tape may be considered for the purpose of the passage of an electric current through its mass, as composed of a bundle of rods of infinitely small sectional area, and it is obvious that if this is so, and there is no reason to question the premise, the current passing in each of these rods or wires acts inductively upon those passing in all the others, and in such a manner as will resist their passage; because, as we know, each current creates around it a series of circles of magnetisation within which the others would be enclosed, and these resent, so to speak, the entrance into them of another current creating magnetic fields of a similar name. Further, we know, by the laws of magneto-electric induction, that these effects, giving rise to apparent resistance, are proportional to the current strength, other things being the same. We know also that in all these cases the current strength depends upon the E.M.F. available, and inversely upon the resistance of the circuit. In other words, the whole thing depends upon the difference of potential between the cloud and the top of the conductor, and inversely upon the resistance of the path or paths chosen, *nolens volens* by the discharging current, so that we come right back to our initial question—What is the path of the discharging current? and what part does "earth" play in the discharge? The apparent increase of the ohmic resistance of any lightning conductor, owing to magneto-electric induction within itself, would really appear to be too small a matter, considering the magnitude of the figures involved, to have any serious bearing upon the question. Here it may be well to state another problem for solution. It is the problem of which the question, "What part does 'earth' play in a lightning discharge" forms a part. It is, what is necessary to protect buildings, electrical instruments, such as telephones and dynamos, or trees and

animals from being struck by dangerous lightning discharges. The answer is, in the writer's opinion, that the E.M.F. available for driving a current through the body to be protected must be reduced below the dangerous point, or below that at which either a dangerously powerful heating or shocking current, or a dangerously powerful spark, can be delivered through the circuit of which the body to be protected forms a part.

It is obvious that this end may be accomplished in two ways only—viz., by interposing in the circuit which it is designed to protect a high resistance, or by shunting the circuit by means of a conductor of such low resistance that the shunted current lowers the E.M.F. at the terminals of the body or instrument to be protected below the danger point. Possibly an example taken from practical electrical engineering work will make this clear.

Suppose that you have an electrical pumping plant which is being worked at an E.M.F. in the mains of 300 volts or thereabouts, and you wish to run incandescent lamps on the same circuit; you have only 100-volt lamps, and the problem is therefore to use these lamps without overheating them. The problem, of course, is a very simple one. You either use three of the lamps in series, or where you cannot use three lamps together within any reasonable distance, you introduce an artificial resistance between one main and one terminal of the lamp. In either case you use up the surplus 200 volts by introducing the additional resistance, reducing the E.M.F. at the terminals of the lamp to the figure you require, 100 volts, thereby only allowing the proper current to pass through it. But you might also have accomplished the object by causing a large current to pass through the mains and through another branch circuit, the current passing being of sufficient magnitude to reduce the voltage at the terminals of the lamp to the same figure as before—viz., 100 volts—by reason of the charge made upon the initial E.M.F. present for the passage of this current through the mains, in opposition to their electrical resistance.

Take the resistance of the mains between the terminals of the dynamo and those of the motor at one ohm, and the normal working current as 20 amperes; the E.M.F. at the terminals of the dynamo being 320 volts, giving 300 volts at the terminals of the lamp. Now bridge across the mains at a point near where you require the lamp with a shunt, having a resistance of 1·5 ohms, which will allow of the passage of a current of 200 amperes. Making use of the usual formula $E = CR$, we find that the passage of this current through the mains absorbs 200 volts, and the E.M.F. at the point where the shunt is connected, while the shunt current is passing, will be only 100 volts.

The above is, of course, only a hypothetical case, though it might occur under such conditions as the waste of power in the mains being of no consideration even when of the large magnitude described, and the shunt circuit might be represented by a motor using that current. Such a case might also arise from defective engineering. The example, whether hypothetical or practical illustrates the two methods that rule for protecting life and property from the current of a high-tension supply, or from lightning.

The first method, the introduction of an artificial resistance into the circuit, is that usually adopted by attendants upon high-tension dynamos, when they place a piece of dry wood near the machine to stand upon while they are oiling, etc., when the machine is running. The second plan is the one that has hitherto been adopted almost universally in the matter of lightning conductors, but which, as the writer understands the matter, Dr. Oliver Lodge says is wrong.

The first plan is also obviously one that could be adopted in case of being caught in a thunderstorm. If one knew where to stand upon a piece of close rock, which itself stood upon ground that did not hold moisture readily, one would have accomplished the object sought after—viz., by introducing an artificial resistance into the circuit, lessened the chances of a dangerous [illegible] passing through one.

It will be evident, h[illegible] whichever plan is chosen [illegible] path [illegible] considerable im-porta[illegible] ample t[illegible] sen the re[illegible] path [illegible] r cond[illegible] question [illegible] arise b[illegible] ath [illegible] se of lig[illegible] *ning*? [illegible] tains [illegible] quires

path for redistribution of its charge, for the expend[illegible] of its stored energy, just as much as either an [illegible] light supply system requires one, or a frictional elec[illegible] machine does. But consider, first, what would [illegible] effect of having a return path of high resistance [illegible] case where you propose to take off a powerful [illegible] current for any purpose. Your high-resistance [illegible] path will prevent your doing it, because you [illegible] unable to get the necessary strength of current throug[illegible]

It must be remembered that in dealing with protec[illegible] from lightning the two classes of cases must be kept [illegible] distinct. If an object is already protected, by the [illegible] from its position a high resistance is offered to any cu[illegible] that can be sent through it from a thundercloud, it re[illegible] no other. But, on the other hand, if the object to be [illegible] tected stands in such a position that the natural resist[illegible] offered to the current that would be sent through it [illegible] a thundercloud is not sufficient to protect it under [illegible] circumstances, and it becomes necessary to protect it [illegible] the other plan, then the high resistance of the return pa[illegible] is an obstacle in the way of accomplishing this. And [illegible] here that the necessity for good, very good earth, appe[illegible] to the writer to come in.

What is the return path, or, if it be preferred, the [illegible] for redistribution of the charge on a thundercloud? [illegible] charge would, as already stated, probably be formed in [illegible] process of the formation of the cloud itself, and by fric[illegible] with the atmosphere as it sailed over the earth. Whence [illegible] this charge come? Evidently principally from [illegible] moisture in the surrounding atmosphere, a little from the air itself. But the fact of a charge of electricity h[illegible] been taken from the atmosphere between the cloud and the earth would cause a current from the earth, and [illegible] buildings, animals, chimneys, etc., producing the phenom[illegible] we know to exist—viz., the charge of an opposite nam[illegible] those portions of the earth's surface, and the objects [illegible] it, immediately under the cloud. When a redistri[illegible] takes place it can only be by means of currents pass[illegible] through the conductors present. The method of re[illegible] bution will, of course, depend upon the conditions [illegible] at the time. Thus the effect of the discharge of one [illegible] might be neutralised by the presence of another, and [illegible] discharge of the cloud might take place not to any obje[illegible] upon the earth, but to another cloud, in which case [illegible] a different set of conditions would be set up. Again, [illegible] cloud might not discharge at all in the neighbourhood where it was generated, and where it acquired the ma[illegible] portion of its charge.

In any case, however, whatever the cause of the redis-tribution, it could only take place by *conduction*. Now, consider, if this true, what it means. It does not m[illegible] that only metals, or the inside of chimney shafts, or [illegible] trees, or animals will take part in the redistribution, b[illegible] that these and every other body which lies in the path [illegible] the E.M.F. present will take its proportion of curr[illegible] according to Ohm's law—*i.e.*, in inverse proportion to the resistances. It should be mentioned here that there [illegible] probably be electromagnetic induction between differ[illegible] portions of the discharging or redistributing current, [illegible] passing through earth, rocks, trees, or any other body, j[illegible] as there will be between the different portions pass[illegible] through a lightning rod. There will also be electroly[illegible] up at different points, both giving rise to counter E.M.F. [illegible] and the current passing in any path will be ruled by the [illegible] E.M.F. available for overcoming the resistance of that pa[illegible] after allowing for these counter E.M.F.'s, just as the curre[illegible] passing in an electric motor would.

Now it will be evident that as the mass of the earth['s] crust takes part very largely in this redistribution or dis-charge, whichever it is called, the current passing in a[illegible] part of that crust will depend upon two things only—the formation of the crust at that particular point, and the surface contact between the principal conductor contain[illegible] in it and the conductor leading to the ground.

Take, for instance, a broad, deep river, such as the Thames or the Mersey; the resistance offered by the river to the discharging or redistributing current must be sma[illegible] [illegible]vided the contact made between it and, say, the end [illegible] [illegible]ctor leading to it is large. On the other hand, t[illegible] [illegible] offered by a hard, impervious rock will be ligh[illegible]

But, as is well known, if the contact with the river is very small, the resistance offered to the current may be high; while even in the case of a hard rock, if we could obtain a large enough surface contact, the resistance might be reduced to moderate dimensions.

But how does this affect the question of the lightning discharge? In the writer's opinion the question is affected by these matters, because in all cases of discharge or redistribution, it is along these paths that the current which carries out the redistribution must flow.

There is a difference of potential between one end of the cloud and one part of the earth, but there is also, by reason of that difference of potential, a further tension between the same part of the earth and neighbouring portions, and no matter how the result may come—either by sparking from the cloud to some object on the earth's surface, by sparking from cloud to cloud, by silent discharge between cloud and surrounding objects, or by the cloud moving on—whenever a redistribution does take place it necessitates currents passing between the parts of the earth, or the objects on it, that are at different potentials, and these currents must pass through the earth's crust, the objects on it, and through the surrounding atmosphere in accordance with the laws already stated.

Now examine the case of a lightning conductor attached to a high building or to a mill chimney. What position does it occupy with reference to the charged cloud overhead?

It is perhaps as well to explode the old idea that the conductor is able to attract all the charge to itself. The lightning-rod forms merely one of many paths open to the discharging or redistributing current. Each of the chimneys of the building, with their soot linings, forms another part. The stone or brickwork of which the building or chimney is composed forms other paths, mainly on account of the moisture held in them.

If the lightning conductor is able to protect the building to which it is attached, it will be because the additional path formed by it for the discharging current has reduced the E.M.F. available below the point at which it can do other mischief.

But if it is to do that, obviously it must be arranged to carry the largest possible current away. Obviously, also, the only way in which this can be accomplished is by making the conductor form a portion of a path of low resistance; and how is this to be done except by connecting it by means of a large surface contact with the mass of the best conductors to be found in the earth's crust where the conductor joints it—in other words, by making *good earth* as electrical engineers understand the term.

The lightning current will not mind ploughing up a few yards of earth when it reaches ground, but there is no reason that it should be allowed to do so if it can be avoided, as it can by making a good earth connection.

A *good earth* would, of course, mean, if available, the bed of a river, wide and deep, connection being made to the water by means of a large metal plate. But, it is replied, if good earth, as you call it, will do the trick, why are buildings struck where the conductors have good earth? Why is a poor sheep struck in the open, standing upon wet ground? Surely he is making good earth. What about side flashes also? Where does good earth come in there? The answer is, and it had better be faced at once, that unless the number of conductors is much multiplied, in the case of large buildings, each conductor making good earth, and, if possible, a separate earth, unless the bed of a large river is available, it is impossible to absolutely ensure protection from lightning. But while it is impossible to ensure absolute protection from lightning, just as it is impossible to ensure immunity from many other things, the one thing that will tend, and the only thing that will tend to protect from lightning is the multiplication before described, all the conductors being *well earthed*.

It is obvious, of course, that where good earth is obtainable fewer conductors are necessary than where it is not. The reason why this is the only plan available is that which has been already mentioned—viz., that the conductor only forms one path of many open to the discharging current, and that it only protects if it is able to reduce the E.M.F. present between the cloud, or the conductor when struck, and surrounding objects below danger point. In the case of a large square building, it might very possibly happen that portions of its roof would be at different potentials, from the very fact of the existence of a conductor on one side; and though one side might be efficiently protected by the conductor placed there, there might be a dangerous E.M.F. still existing after discharge between another part of the cloud and some other part of the building. The remedy is obviously, multiply conductors and *earth them all* separately. The same reasoning applies to side flashes. They are due to the existence of an E.M.F. between the conductor while carrying out its office of discharging or redistributing, and the object to which the flash passes, which the conductor has not been able to kill.

It should be noted, however, that side flashes cannot take place except to objects which form part of a circuit of such resistance that a current can pass through this path, including the air space over which the flash passes. Gas brackets and pipes are the most usual recipients of side flashes, the reason being that they, being in connection with the large mass of main pipes lying in the ground, forming good earth, affords such a path as has been described. The remedy is, as before, multiply the lightning conductors, and apply the high resistance method to the gas-pipes and other possible recipients. Place them as far from the path of discharge as you can.

The case of animals and trees being struck in the open field arises from the fact that there is no discharging path near, and therefore a dangerous E.M.F. is present, the actual path of the discharge being determined by special conditions in each case.

The remedy would be here, as in other cases, to fix a number of conductors about a field where animals grazed during thunder weather, always getting as good earth as possible. A similar plan would probably protect valuable plantations of forest trees.

In conclusion, the writer would point, in confirmation of his views, to the comparative immunity of towns from the effect of lightning discharges, and he attributes this immunity to the fact that so many paths are open for the discharge of the thundercloud. Most of them have a high resistance, and do not make good earth, but their infinite multiplication gives the same result, even to the *good earth*, in another form. Suppose, for instance, the resistance of the column of smoky hot air, soot-lined chimney, fire-grate, and foundation together amount to 1,000 ohms, a thousand such paths will bring the resistance to only one ohm; while in the case of a very large city, the combined resistance of all the paths open to the discharging current would be very small indeed.

The writer would also point to the fact that though lightning has frequently been seen in the workings of a mine, and has often pulled down colliery chimneys, and done damage at the pit bottom, no damage has ever been done by it in the mine itself, the coal, rails, etc., acting as conductors to distribute the charge, and the damage done at the pit bottom being due to the sudden break from a conductor of low resistance to one of high resistance, without good surface contact—without, in fact, a good connection to earth.

The writer has not touched upon the static side of the question, but it is obvious that most of the remarks given above apply equally, whether the matter be looked at from the electrostatic or electro-dynamic point of view. Each conductor, each body that will or does conduct, not only does so, but it dissipates a portion of the charge from the electrostatic capacity of the condenser or condensers, of which it forms a part; and this is surely an argument for getting the conducting surface to which the discharging current is conveyed as large as possible. That is getting *good earth*.

It should perhaps be noted that the office of *good* "earth" would be very well filled by the congregation together of a number of large masses of metal, in more or less good connection, electrically speaking, such as a large town built entirely of iron—a thing which may perhaps one day come to pass. Failing this, however, our next best substitute is the earth's crust, solely on account of its large proportions, and this is only available where we can get good connection to the principal conductor in it, the moisture that is always present.

future? We are acting as if our conclusions
infallible; whereas half a century hence may
them to have been as far from the truth as
conclusions of the Greeks in astronomy. Di
units by all means; but not through a formal
informal meeting of sections, but by means
well-organised committee.

CITY AND SOUTH LONDON RAILWAY.

"I hope that the future profits of the line wil
on steadily increasing, and that it will not be so
long before I may have the pleasure of standing
and feeling that we have earned a substantial
dend. But that rests with the future, and I do
like to prophesy on these points." Thus
chairman of the City and South London Rail
Company at the half-yearly meeting held on Tue
last. Everything was going on very well.
Board could affirm that their system of electric
motion would work, and could go even furt
and say that it had worked satisfactorily. B
would it pay? Well, the future must ans
that question. They hoped and believed it wo
At present, however, the company have
just managed to pay the interest on their de
tures, £4,137, and to carry forward a s
balance of £555. And unless the weekly recei
which we have published regularly in our
Notes, show some signs of expansion, it does
look as if a much better financial statement aw
the shareholders next winter. The Board are d
their best to fill up the trains during the middle

de Ville; (9) 31, Rue des Bourdonnais. These two circuits have double cables, and each constitute two parallel circuits, including or neglecting the batteries of certain stations in which these are cut out by a switch. The object of this arrangement is to balance the different sub stations during normal periods, and to allow of provisional grouping in case of accidents.

The third charging circuit fed from the Rue Dieu has a single cable, and includes the following sub-stations—viz., (1) 83, Rue Turbigo; (2) 9, Rue Bourg l'Abbé; (3) Passage Lemoine; (4) 4, Rue d'Hauteville; (5) 13, Boulevard Voltaire.

Finally, there is a fourth station working by means of steam in the Boulevard Richard-Lenoir, having two charging circuits, one of which feeds sub-stations at 6, Rue Malher and 20, Rue de la Verrerie, and the other, sub-stations at 70, Boulevard Beaumarchais and 6, Rue de Franche-Comté. These four circuits are completely separate and autonomous; at the same time there are localities where auxiliary cables, called dead cables, afford connections between neighbouring circuits, which in regular working are cut out, but which, in case of accident on any of these circuits, enable it to be supplied by one of the others. The charging current is maintained constant at 200 amperes; the pressure varies directly as the number of accumulators under charge, and may rise to 2,400 volts. There are two batteries of accumulators in each sub-station in order that the permanence of the discharge on the secondary circuit supplying customers may be assured.

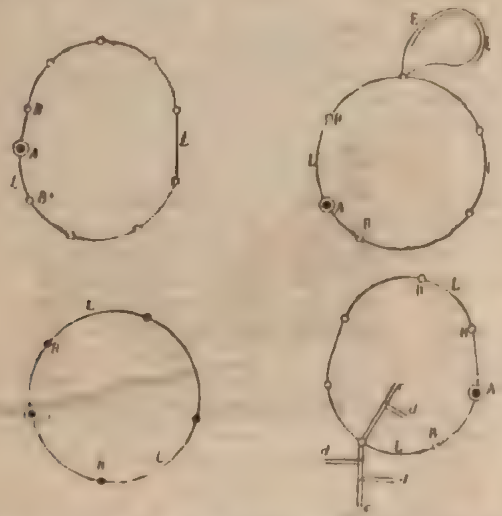

Fig. 1.—A A A A. Charging stations. B B B. Sub-stations in series. c c. Radiating circuit. d d. Customers' leads. E E. Lamp circuits. L L L. Charging circuits.

The secondary circuit is laid in two different ways. In the central parts of the city it consists of circuits radiating round the sub-station, about 250 metres in length, on which are placed special installations; the excess charge in the houses of the customers nearest to the station is absorbed by rheostats on their premises. All the sub-stations of the Retiro circuit, of the Bourse de Commerce, and of the Turbigo, Rue Bourg l'Abbé, and Passage Lemoine circuits, are arranged on this principle. All the other stations near the peripheral districts feed loop circuits, the two conductors, both positive and negative, returning under the footway on the opposite side of the street, so as to serve both sides. The conductors are of bare wire, placed in troughs and mounted on porcelain insulators. The charging cables, as well as those of the radiating circuits, are insulated by a coating of indiarubber, covered with a protecting envelope of lead and hemp. The first are very highly insulated; their cost reaching to 20,000f. per kilometre; the second mentioned, which are not so costly, work out to 16,000f. per kilometre.

The distributing arrangements adopted, and those which proceed therefrom, are graphically summed up in Fig. 1. The general idea has been worked out from the suggestions of M. Solignac. The mention of his name reminds us that we have to complete the exposition of the economy of the sector. It was a question of working with alternate-current transformers side by side with accumulators. How was this done? By means of an apparatus called "the undu[lator]" devised by M. Solignac, the object of which was to e[nable] transformers on continuous current circuits. We s[aw] apparatus working at the Centenary Exhibition of 18[88] fed Jablochkoff candles by Gaulard and Gibbs transfo[rmers] with a current obtained from a continuous-current dy[namo]. If our memory does not deceive us, the ruling princ[iple] of this device consists in placing two transformers in th[e] stations, putting an "undulator" in shunt with each [trans]former, and in the transformer branch a current re[...]

Fig. 2.

The "undulator" is a kind of rotating commutator, [which] places in circuit with the first transformer a seri[es of] resistances so arranged that at the moment of the circuit, indicated at a in Fig. 2, no current passes [in the] corresponding transformer, whilst the whole current [passes] in the second transformer and in the line.

As the "undulator" rotates, so the resistances b, c, d, are inserted in shunt with the transformer; the [...] increases in the latter as shown by the curve a b, [...] up to the point of complete opening of the circuit, [when] it receives all the current, that is at the point b. Con[tinued] working of the apparatus again successively cuts [out]

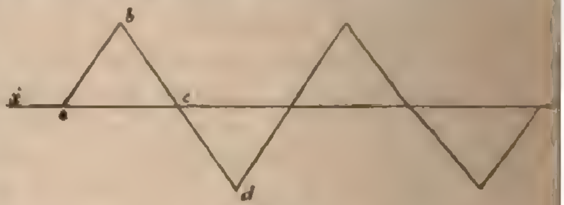

Fig. 3.

resistances g, f, e, d, c, b, up to the moment wh[en the] transformer is short circuited. This point is util[ised to] reverse the poles of the transformer, and, as a conseq[uence] a new curve, c d, is described below the axis, x x'. [The] undulator is always in duplicate, so that when one [trans]former is short circuited the other is not, the objec[t being] to equalise the work on the machine.

(To be continued.)

A NON-INDUCTIVE WATTMETER.

Great difficulty has always been felt in measuring [power] with alternate currents. The ordinary wattmeter, [...] accurate with direct currents when a correction is ma[de for] the power taken by the instrument itself, is of little [use] for use with alternate currents, as the time-constant [of the] fine wire circuit is appreciable. If the pressure and c[urrent] are in step, as is the case when an alternate press[ure is] applied to a resistance, such a wattmeter reads to[o low]. If a pressure is applied to an inductive circuit, on the [other] hand, the reading may be much too high.

Messrs. Swinburne and Co. have brought out a [watt]meter specially designed to avoid these errors. The m[oving] coil contains but few turns, and these are wound on [a] mica former. The coil is held by top and bottom str[etched] wires. External resistances are supplied, wound wi[th] alternate layers right and left handed. The time-co[nstant] of the fine wire circuit is thus made sensibly equal to [...]. Readings are taken by means of a torsion head in the [usual] way, but for measurements of minute powers, su[ch as] hundredths of a watt, a mirror is used. These watt[meters] are wound to suit any range from 3,000 volts, and fr[om ...] amperes downwards.

hey are stated by the makers to read accurately on non ictive resistances, and on inductive circuits in which the luct of the pressure and current is 50 times the real er.

he wattmeter has the advantage over electrometer hods, that it does not involve the very serious troubles resistances. Mr. Swinburne recently described an trometer which reads power directly, which, though it the work of the three voltmeters discussed by Messrs. ton, Sumpner, and Swinburne soon after, unfortunately

ires resistances. Dr. Fleming has enormously improved three-instrument method by substituting amperemeters, we thus have unimpeachable means of verifying the meter. If this wattmeter does what the makers claim t, it will be exceedingly valuable to alternating-current neers.

'ERIMENTS WITH ALTERNATE CURRENTS OF ERY HIGH FREQUENCY AND THEIR APPLICA- ON TO METHODS OF ARTIFICIAL ILLUMINA- ON.*

BY NIKOLA TESLA.

(Continued from page 131.)

ith these rapidly alternating potentials there is, how- no necessity of enclosing two blocks in a globe, but a e block, as in Fig. 20, or filament, Fig. 23, may be used. potential in this case must of course be higher, but easily obtainable, and besides it is not necessarily erous.

ie facility with which the button or filament in such a is brought to incandescence, other things being equal,

FIG. 23.

nds on the size of the globe. If a perfect vacuum be obtained, the size of the globe would not be of rtance, for then the heating would be wholly due to urging of the charges, and all the energy would be off to the surroundings by radiation. But this can occur in practice. There is always some gas left in the globe, and although the exhaustion may be carried to the highest degree, still the space inside of the bulb must be considered as conducting when such high potentials are used, and I assume that in estimating the energy that may be given off from the filament to the surroundings we may consider the inside surface of the bulb as one coating of a condenser, the air and other objects surrounding the bulb forming the other coating. When the alternations are very low there is no doubt that a considerable portion of the energy is given off by the electrification of the surrounding air.

In order to study this subject better, I carried on some experiments with excessively high potentials and low frequencies. I then observed that when the hand is approached to the bulb—the filament being connected with one terminal of the coil—a powerful vibration is felt, being due to the attraction and repulsion of the molecules of the air which are electrified by induction through the glass. In some cases where the action is very intense I have been able to hear a sound, which must be due to the same cause.

When the alternations are low, one is apt to get an excessively powerful shock from the bulb. In general, when one attaches bulbs or objects of some size to the terminals of the coil, one should look out for the rise of potential, for it may happen that by merely connecting a bulb or plate to the terminal, the potential may rise to many times its original value. When lamps are attached to the terminals, as illustrated in Fig. 24, then the capacity of the bulbs should be such as to give the maximum rise of potential under the existing conditions. In this manner one may obtain the required potential with fewer turns of wire.

The life of such lamps as described above depends, of course, largely on the degree of exhaustion, but to some extent also on the shape of the block of refractory

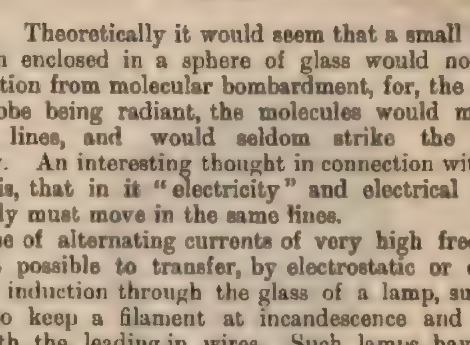

FIG. 24.

material. Theoretically it would seem that a small sphere of carbon enclosed in a sphere of glass would not suffer deterioration from molecular bombardment, for, the matter in the globe being radiant, the molecules would move in straight lines, and would seldom strike the sphere obliquely. An interesting thought in connection with such a lamp is, that in it "electricity" and electrical energy apparently must move in the same lines.

The use of alternating currents of very high frequency makes it possible to transfer, by electrostatic or electromagnetic induction through the glass of a lamp, sufficient energy to keep a filament at incandescence and so do away with the leading-in wires. Such lamps have been proposed, but for want of proper apparatus they have not been successfully operated. Many forms of lamps on this principle, with continuous and broken filaments, have been constructed by me and experimented upon. When using a secondary enclosed within the lamp, a condenser is advantageously combined with the secondary. When the transference is effected by electrostatic induction, the potentials used are, of course, very high with frequencies obtainable from a machine. For instance, with a condenser surface of 40 centimetres square, which is not impracticably large, and with glass of good quality 1 mm. thick, using currents alternating 20,000 times a second, the potential required is approximately 9,000 volts. This may seem large, but since each lamp may be included in the secondary of a transformer of very small dimensions, it would not be inconvenient, and, moreover, it would not produce fatal injury. The transformers would all be preferably in series. The regulation would offer no difficulties, as with currents

cture delivered before the American Institute of Electrical eers at Columbia College, New York, May 20.

of such frequencies it is very easy to maintain a constant current.

In the accompanying engravings some of the types of lamps of this kind are shown. Fig. 25 is such a lamp with a broken filament, and Fig. 26A and Fig. 26B one with a single outside and inside coating and a single filament. I have also made lamps with two outside and inside coatings, and a continuous loop connecting the latter. Such lamps have been operated by me with current impulses of the enormous frequencies obtainable by the disruptive discharge of condensers.

The disruptive discharge of a condenser is especially suited for operating such lamps—with no outward electrical connections—by means of electromagnetic induction, the electromagnetic inductive effects being excessively high;

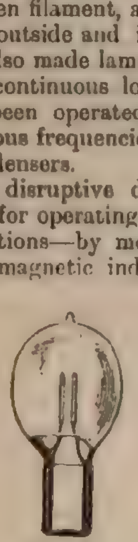

FIG. 25.

FIG. 26B.

FIG. 26A.

and I have been able to produce the desired incandescence with only a few short turns of wire. Incandescence may also be produced in this manner in a simple closed filament.

Leaving, now, out of consideration the practicability of such lamps, I would only say that they possess a beautiful and desirable feature—namely, that they can be rendered at will more or less brilliant, simply by altering the relative position of the outside and inside condenser coatings, or inducing and induced circuits.

FIG. 27.

When a lamp is lighted by connecting it to one terminal only of the source, this may be facilitated by providing the globe with an outside condenser coating, which serves at the same time as a reflector, and connecting this to an insulated body of some size. Lamps of this kind are illustrated in Fig. 27 and Fig. 28. Fig. 29 shows the plan of connections. The brilliancy of the lamp may in this case be regulated within wide limits by varying the size of the insulated metal plate to which the coating is connected.

It is likewise practicable to light with one leading wire lamps, such as illustrated in Fig. 21 and Fig. 22, by connecting one terminal of the lamp to one termi source, and the other to an insulated body of the size. In all cases the insulated body serves to give energy into the surrounding space, and is equiva return wire. Obviously, in the two last-named cases, of connecting the wires to an insulated body, con may be made to the ground.

The experiments which will prove most suggestiv most interest to the investigator are probably th formed with exhausted tubes. As might be antici source of such rapidly alternating potentials is ca exciting the tubes at a considerable distance, and t effects produced are remarkable.

During my investigations in this line I endeavo excite tubes, devoid of any electrodes, by electrom induction, making the tube the secondary of the in device, and passing through the primary the disch a Leyden jar. These tubes were made of many and I was able to obtain luminous effects which thought were due wholly to electromagnetic ind But on carefully investigating the phenomena I fo the effects produced were more of an electrostatic It may be attributed to this circumstance that this exciting tubes is very wasteful—namely, the primar being closed, the potential, and consequently the static inductive effect is much diminished.

FIG. 28.

When an induction coil, operated as above desc used, there is no doubt that the tubes are excited by static induction, and that electromagnetic induct little, if anything, to do with the phenomena.

This is evident from many experiments. For insta tube be taken in one hand, the observer being near th is brilliantly lighted and remains so in no matter what it is held relatively to the observer's body Were th electromagnetic, the tube could not be lighted w observer's body is interposed between it and the at least its luminosity should be considerably dim When the tube is held exactly over the centre of th the latter being wound in sections and the primary

FIG. 29.

symmetrically to the secondary—it may remain com dark, whereas it is rendered intensely luminous by it slightly to the right or left from the centre of th It does not light because in the middle both halves coil neutralise each other, and the electric potential If the action were electromagnetic, the tube shoul best in the plane through the centre of the coil, si electromagnetic effect there should be a maximum an arc is established between the terminals, the tub lamps in the vicinity of the coil go out, but light u when the arc is broken, on account of the rise of po Yet the electromagnetic effect should be practical same in both cases.

By placing a tube at some distance from the co nearer to one terminal—preferably at a point on th

of the coil—one may light it by touching the remote terminal with an insulated body of some size or with the hand, thereby raising the potential at that terminal nearer to the tube. If the tube is shifted nearer to the coil so that it is lighted by the action of the nearer terminal, it may be made to go out by holding, on an insulated support, the end of a wire connected to the remote terminal, in the vicinity of the nearer terminal, by this means counteracting the action of the latter upon the tube. These effects are evidently electrostatic. Likewise, when a tube is placed at a considerable distance from the coil, the observer may, standing upon an insulated support, between coil and tube, light the latter by approaching the hand to it; or he may even render it luminous by simply stepping between it and the coil. This would be impossible with electromagnetic induction, for the body of the observer would act as a screen.

When the coil is energised by excessively weak currents, the experimenter may, by touching one terminal of the coil with the tube, extinguish the latter, and may again light it by bringing it out of contact with the terminal and allowing a small arc to form. This is clearly due to the respective lowering and raising of the potential at that terminal. In the above experiment, when the tube is lighted through a small arc, it may go out when the arc is broken, because the electrostatic inductive effect alone is too weak, though the potential may be much higher; but when the arc is established, the electrification of the end of the tube is much greater, and it consequently lights.

If a tube is lighted by holding it near to the coil, and in the hand which is remote, by grasping the tube anywhere with the other hand, the part between the hands is rendered dark, and the singular effect of wiping out the light of the tube may be produced by passing the hand quickly along the tube and at the same time withdrawing it gently from the coil, judging properly the distance so that the tube remains dark afterwards.

If the primary coil is placed sidewise, as in Fig. 17B for instance, and an exhausted tube be introduced from the other side in the hollow space, the tube is lighted most intensely because of the increased condenser action, and in this position the striæ are most sharply defined. In all these experiments described, and in many others, the action is clearly electrostatic.

The effects of screening also indicate the electrostatic nature of the phenomena and show something of the nature of electrification through the air. For instance, if a tube be placed in the direction of the axis of the coil, and an insulated metal plate be interposed, the tube will generally increase in brilliancy, or if it be too far from the coil to light, it may even be rendered luminous by interposing an insulated metal plate. The magnitude of the effects depends to some extent on the size of the plate. But if the metal plate be connected by a wire to the ground, its interposition will always make the tube go out, even if it be very near the coil. In general, the interposition of a body between the coil and tube, increases or diminishes the brilliancy of the tube, or its facility to light up, according to whether it increases or diminishes the electrification. When experimenting with an insulated plate, the plate should not be taken too large, else it will generally produce a weakening effect by reason of its great facility for giving off energy to the surroundings.

If a tube be lighted at some distance from the coil, and a plate of hard rubber or other insulating substance be interposed, the tube may be made to go out. The interposition of the dielectric in this case only slightly increases the inductive effect, but diminishes considerably the electrification through the air.

In all the cases, then, when we excite luminosity in exhausted tubes by means of such a coil, the effect is due to the rapidly alternating electrostatic potential; and, furthermore, it must be attributed to the harmonic alternation produced directly by the machine, and not to any superimposed vibration which might be thought to exist. Such superimposed vibrations are impossible when we work with an alternate-current machine. If a spring be gradually tightened and released, it does not perform independent vibrations; for this a sudden release is necessary. So with the alternate currents from a dynamo machine: the medium is harmonically strained and released, this giving rise to only one kind of waves; a sudden contact or break, or a sudden giving way of the dielectric, as in the disruptive discharge of a Leyden jar, are essential for the production of superimposed waves.

In all the last described experiments, tubes devoid of any electrodes may be used, and there is no difficulty in producing by their means sufficient light to read by. The light effect is, however, considerably increased by the use of phosphorescent bodies such as yttria, uranium, glass, etc. A difficulty will be found when the phosphorescent material is used, for with these powerful effects it is carried gradually away, and it is preferable to use material in the form of a solid.

Instead of depending on induction at a distance to light the tube, the same may be provided with an external—and, if desired, also with an internal—condenser coating, and it may then be suspended anywhere in the room from a conductor connected to one terminal of the coil, and in this manner a soft illumination may be provided.

(To be continued.)

NOTES ON ELECTRICAL WORK IN MINES.*

BY ALBION T. SNELL, ASSOC.M.I.C.E., M.I.E.E.

Perhaps no branch of engineering has received more attention of late than the application of electricity to the ordinary purposes of mining. At home, on the Continent, and in America, electrical energy has been applied to this work, and in the majority of instances with success. The general theory underlying the application of this power has been discussed again and again, and numerous illustrations have from time to time been given, so that in reopening the matter before the South Wales Institute of Engineers, I feel some difficulty in selecting the precise lines for my paper. The theoretical side of the question is not a suitable subject for discussion here, and from the practical point of view, plants illustrative of pumping, hauling, coal cutting, etc., have been shown so often as to lessen the immediate interest. My object in reading this paper, then, is simply to open a discussion to induce members to give their various experiences of electric work, so that by a comparison of such data we may be enabled to form an adequate idea of the work now being performed in collieries by this agency, and I hope that there will ensue a lengthy discussion which will materially add to the practical knowledge now extant on this important department of engineering.

With this view I purpose, even at the risk of describing what has already been published elsewhere, to briefly refer to one or two of the more important plants now running in Great Britain, and especially a pumping plant at Messrs. Crawshay Brothers' Newbridge Rhondda Colliery. These plants have been erected under my own superintendence and I have selected them because they are applicable for lighting as well as for power, and are so installed that the energy may be divided into separate units at different parts of the circuit, just as several engines can be driven off a compressed air system.

In February, 1890, the question of "The Electrical Distribution of Energy over Extended Areas in Mines" was discussed before the Federated Institute of Mining Engineers, and I then proposed the use of over-compounded dynamos for this purpose. When the matter was also discussed at the Newcastle meeting in 1891, I was able to state that several installations designed on these lines had been working successfully for some time. One of these was the Newbridge Rhondda Colliery pumping plant, and by the courtesy of Mr. Abraham, the manager, I am able to bring the following details before you. This plant is typical of the system; it is successful here, and there is no reason to prevent it being equally successful under similar conditions in other pits. The problem was to drive two pumps off the same set of mains. The pumps were 700 yards apart, and it was required to make each independent, so as to be stopped or started without affecting

* Paper taken as read at the annual meeting of the South Wales Institute of Engineers, July 27, 1891.

the speed of the other. It was also imperative that the electric light should be used at the pumping stations, at the pit bank and pit bottom; and, further, there was to be only one dynamo. These conditions assumed that the pressure would be practically constant throughout the circuit. In practice, it is impossible to secure an absolutely constant pressure all over the system, owing to the resistance of the mains themselves; but by over-compounding the dynamo, so as to give a constant pressure at a point near the centre of the system, it is possible to approximate very closely to the required conditions. How well the case has been met is apparent when I mention that both the pumps can be switched off without appreciably raising the voltage of the lamps. The dynamo is one of our Sh. D. C. 12/16 type, and running at 800 revolutions per minute gives a pressure of 300 volts and 60 amperes. Each of the motors gives 7 b.h.p., and runs at 800 revolutions per minute. The lamps are coupled in series of three. The pumps are three-throw rams, 4in. in diameter by 9in. stroke. Mr. Abraham tells me the plant has been perfectly successful from the first, and he hopes to extend the use of electricity at an early date.

Another interesting application of electricity which is likely to be of use in certain cases is a new system of haulage patented by Messrs. G. B. Walker, of Wharncliffe Silkstone, and Immisch, of the G. E. P. and T. Company. In this system the loco does not depend for grip on its own weight, but gets a direct pull on a cable lying between the rails, parallel to the road, and fixed at either end. This cable passes over a sprocket wheel on the loco or trolley, and is driven through suitable gearing by an electric motor. The motor is supplied with energy from a bare copper wire arranged on the roof or the side of the road. It is needless to say that such a trolley is only applicable to roads free from gas. The chief advantage of the system lies in the light weight of the trolley in proportion to the heavy tractive effort it can exert. It will be principally used as an auxiliary power on short steep lengths of otherwise fairly level roads, where horses are generally used, and will be found in many cases to be a great saving in horseflesh. A loco or trolley of this type has been running at Wharncliffe Silkstone Collieries for nearly 12 months on a brow 500 yards long, with a grade averaging 1 in 9. It raises loads of about five tons at a speed of three miles per hour. Formerly, 12 horses were required for the work, and even with this number it was so severe that it was not deemed advisable to keep the same animals at it for more than six months at a time. Mr. Allison, my assistant, who erected the line, gives me the following figures, roughly measured, which will be interesting from the electrical point of view:

Rolling load	5 corves	4 tons.
Average speed	2·65 miles per hour.	
Average grade	1 in 9½	
Grade 1 in 12	Amperes, 45	Volts, 180.
Grade 1 in 11	Amperes, 50	Volts, 190.
Grade 1 in 10	Amperes, 55	Volts, 195.
Grade 1 in 9	Amperes, 65	Volts, 200.
Grade 1 in 8	Amperes, 70	Volts, 205.

Since the above figures were taken, a larger dynamo has been installed, and the loco will now do more work.

The loco trolley is unnecessarily heavy for the particular work, and was adapted for existing material; considerable improvements can be made in the design in future. The motor is rated at 10 brake horse-power.

Another interesting application of the compound parallel system is the installation at Andrew's House Pit, Durham. By the courtesy of Mr. Cuthbert Berkley I am able to give the following details: The plant comprises a dynamo, three motors, cables, and three dip pumps. The pumps are respectively 1,500, 1,800, and 2,000 yards in bye; the one nearest the shaft is driven by a 4-h.p. motor, the others each work by motors of 2-h.p. The dynamo gives 250 volts and 40 amperes. The total capacity of the plant is thus small, but it is interesting on account of the distance between the pumps and the length of the cable. A few lamps are run at each of the pump stations and also in the engine-house. The dynamo is arranged to compound for constant potential at about 1,500 yards in bye. But owing to the length of cable the pressure is not maintained so

uniformly as at Newbridge Rhondda installation.
these motors has replaced a crank which required 12
to keep it running through the 24 hours. The pl
now been at work for nearly two years. I may men
passing that a wire rope is used for the return,
difficulty has been experienced from this; but
pressure were higher, or the work larger, I should
an insulated return.

In Bohemia, my company erected last year two pl
some importance in the history of mining in that d
they being the first application of electricity to
work there. The first is at the Standard Tin Com
St. Mauritius Mine. The dynamo is placed below
and is driven by a turbine, the water being led down
by suitable pipes. The motor is arranged to work
of lift pumps with spears 40 metres long, and also
ore through the same vertical distance. When the
lation was first made the lower levels were drowned
the electric plant had to pump them dry before work
be resumed. This was successfuly accomplished
shorter time than the engineers expected, and ore
being regularly raised by the plant. The power
motor is about 20 horse. The second instance is at
at one of the brown coal mines; here the main venti
is produced by a fan driven by electricity, and
believe, the only mine where this is the case. The dy
is driven by a turbine about half a mile away from
house, and the current is carried by bare wires
on poles with fluid insulators. The power of the
approximately 25 horse. The fan has now been
for about 12 months, and the manager reports th
working perfectly satisfactorily.

We are now building a very interesting plant
illustrates the conversion of water power into el
energy and its utilisation for light and power.
thousand yards from the Greenside Lead Mine,
Ullswater, there is a waterfall of upwards of 100
turbine running at 1,000 revolutions per mi
coupled by a belt to one of our 100 e.h.p. fo
transmission dynamos, wound in compound to gi
volts and about 900 amperes. The energy is
mitted by a bare cable ($^{19}/_{15}$ S.W.G.) carried on p
the mine mouth, and there lead-covered cables are
convey the electricity to the various motors. Th
at once run a winding plant of 10 b.h.p., a pumping
of 10 b.h.p., and another winding plant of 20 b
under consideration. Electric light will be used at di
points of the line, and other motors will soon be in
for various purposes. Other examples might be
but the preceding cases are fairly representative
work now being done.

Every system of transmitting energy must nece
entail certain risks peculiar to itself; therefore it
surprising that we find such difficulties in connecti
the use of electricity in mines. There is no doubt th
limits of these difficulties are very imperfectly und
by many mining engineers, and a few remarks
subject may not be uninteresting. There are two
difficulties to contend with which may or may
dangerous. The first is the risk from shocks. The
be received from any part of the circuit, if the insta
be faulty, and under any circumstances from the b
commutator, and terminals of the dynamo and
The danger to be apprehended from electricity
account depends primarily on the pressure of the
Opinions are very much divided as to the number o
necessary to cause death; but as, owing to difficul
installation, the pressure in mines is usually limited
volts or thereabouts, there is no fear of a fatal a
under any ordinary conditions. I have installed
plants of about this pressure, and have never h
a single injury occurring to either the attenda
the miners, although shocks have necessarily bee
quent. At St. John's Colliery, Normanton, we
been working for rather more than three years
maximum pressure of 700 volts, without a single a
happening from this cause; and further, no casualty
electrical shock in any other mine in England has
knowledge been heard of; consequently, I ventu
think that this danger is practically negligible. The

fficulty which confronts us is the risk from fire, which ay occur in two ways: by sparking at the commutator us may be fired; or through a faulty connection or a bad ak, some part of the circuit may become heated and may t fire to timber. These dangers have frequently been iscussed, but as a matter of fact no serious accident has ccurred from the use of electricity, and should ordinary recautions be taken, and the plant be supplied and erected y a responsible firm, the chance of trouble on this score extremely slight. Let us first look at the risks that elong to the cables themselves. It has been rightly urmised that in the event of a heavy fall of the roof reaking them, there may be a spark if ordinary single ables are used, but this danger may be minimised by using oncentric cables; for if such a cable be broken by a fall, he mains will be short-circuited and the cut-out on the urface will fuse, thus cutting off the supply of electricity. n most cases, however, the cable is torn from its supports and simply buried beneath the stones, the strength of the conductor being greater than that of the supports. I have known several cases of this sort and the cables continued n use until the fall was removed, after which, being little he worse, they were re-erected. Even assuming that the cables should break, it by no means follows that the spark, if any, would be intense enough to fire gas, nor that gas would be there in sufficient quantities to be dangerous. I take it that risks of this kind are about on a par with the possibilities of a safety lamp exploding gas through a fracture of the glass which is liable to happen at any time by an accident. In fact, on the whole, I should think this danger is far greater than that from electric cables. But we are accustomed to the breakage of safety lamps, and not, as yet, to electrical work; and this is the chief point of difference.

The sparking at the brushes and commutator introduces a question of a different character altogether. Although in theory a well designed motor with commutator and brushes in good order is sparkless, certainly so far as not to fire gas, yet in practice, owing to wear and tear and possibly want of attention, all motors may at times spark badly. Then arises the question, will those sparks ignite gas? In 1888, when speaking on this subject before the Midland Mining Institute, I gave it as my opinion that the sparks at the brushes of a motor would not readily fire gas on account of their low temperature. This low temperature is due to the large mass of metal in contact with them. To make this point clear I made the following experiment: In a wooden box about 6ft. long with an internal cross section of a square foot, I put a small motor and a gas gauge; a glass window was arranged in the centre of the box so that the gauge could be read and the sparking noted. One end of the box was closed and the other fitted with a hinged door. Ordinary coal gas was then admitted at the closed end, and the motor started. The mixture of air and gas in the box was varied through the most explosive ranges and the motor ran for half-an-hour without firing the gas, although the brushes were sparking more than normally. These were then shifted so as to cause excessive sparking, thus heating both brushes and commutator, the heat at the points of the former being so great that oxide of copper was formed and deposited on them in a white film. At this point the gas exploded. Marsh gas and air explode at about 1,000deg. C. (1,832deg. F.) according to the mixture. It would appear to follow that although under normal conditions there would be little danger of a motor igniting gas, yet, if by any means the brushes and commutator became heated beyond a certain intermediate point, this danger would arise; and if motors are to be used in fiery mines it will be necessary to protect them.

Two ways of doing this suggest themselves. The one is to enclose the entire armature and commutator in a dust-tight metal box sufficiently strong to resist the force of the explosion of possible gas within it; and the other is to box in the commutator and brushes only. The former method has the advantage of also guarding against sparks caused by a possible short circuit on the armature. The second method does not protect the armature winding at all, but it reduces to a minimum the volume of gas which may be exploded by sparks. Both methods are good in their way, and, by proper attention to details, I believe that with either the risks will be comparatively slight. Of course, the best protection is ample ventilation, for if the faces are swept with plenty of fresh air, and the roof properly packed and looked after, there can be no danger from the cause in question. The protection of the motor should only be expected to act as a safeguard against "blowers," because under ordinary mining regulations men would not be allowed to work in a fiery atmosphere. If the motor be fixed at a pump or hauling engine, the difficulties are materially lessened, for the air would not be foul in such places, and if the "blower" worked against the main air-way there would be ample time for the men to switch off the motor before withdrawing, or it could be stopped from the surface.

THE ELECTRIC TRANSMISSION OF POWER.*

BY GISBERT KAPP.

LECTURE III.

(*Concluded from page 138.*)

We must imagine this magnet alternately shrinking into nothing, and growing larger and stronger; also reversing its polarity each time that it passes through its zero condition. In the apparatus shown by Fig. 9, therefore, rotation of a real magnet on the left produces merely an oscillating magnetic field on the right. As you know, a magnetic field may be represented graphically, in direction and magnitude, by a straight line; and in this particular case the line so representing the oscillating field is the projection of the radius, O n, on the vertical M_1 M_1, if the length of the radius, O n, represents the strength of the field at maximum current. At the moment to which our diagram refers, our collapsible magnet will, therefore, have grown to the strength represented by the length, s_1 n_1; and, if there were no lag, the real revolving magnet would at that moment occupy the position S N. As there must be some loss in the transmission, I have shown N at a larger radius than n. If there is lag, then n and N will not lie on the same radius, but n will occupy, say, the position n', and the strength of the oscillating field will be n_1'. s_1'. The practical effect of lag is this, that the revolving magnet will have passed the vertical position shown in the diagram by the time the current has reached its maximum; and I can, therefore, eliminate the lag from the graphic diagram, by assuming that the revolving magnet has been shifted back through an angle equal to the angle of lag in this diagram, but left in its true position in the diagram representing the apparatus itself. In Fig. 9, the coils on the ring on the right hand are placed on the horizontal diameter. If, as in Fig. 10, I place them on the vertical diameter, the resulting oscillating field will be horizontal—namely, on the line M_2 M_2; and the projection of n on the vertical must be taken over to the horizontal, as shown by the dotted quarter circle. Let us now suppose that we have both horizontal and vertical coils on the ring, as shown in this figure, then the combined effect of these coils will be to produce an oscillating field on the line R R, the strength of the field being, as you will easily understand, about 40 per cent. greater than in either of the former cases; but still the field is not a revolving one. I can show you the production of an oscillating field, as here explained, by means of a mechanical model.

Up to the present, then, we have not advanced in the solution of our problem. We have produced at the distant points an oscillating field, but what we want there is a revolving field, and to get this we must duplicate the apparatus shown in Fig. 9 by putting horizontal coils on the generator and vertical coils on the motor ring, in addition to the coils already there. This arrangement is shown in Fig. 11. Now, the field produced by the coils 1 1 is given by the projection of O n on the vertical, and that produced by the coils 2 2 is given by the projection of O n on the horizontal. The resultant of these two fields is, therefore, O n, the point n revolving round O as a centre on the circle, R. The effect of revolving a real magnet within the generator ring is, then, to produce a revolving magnetic field of the strength O n within the motor ring, a kind of revolving phantom magnet which, for our purpose, is quite as suitable as a real magnet. I can also show you this effect by means of the mechanical model.

You observe that in Diagram 11 four wires are shown, connecting the generating and receiving machines. Now, as the absolute potential of any of these wires may be chosen arbitrarily, there is obviously nothing against choosing it at such a value as will make it coincide with the absolute potential of another wire not belonging to the same circuit. We might thus, for instance, equalise the potential between the wires A and B by connecting them at either

* Cantor lectures delivered before the Society of Arts.

terminus, as shown by dotted lines, and not disturb in any way the satisfactory working of the machines. Or, better still, we may omit one of the wires altogether, and use the other as a common wire for both circuits, and thus reduce the total number of wires to three. The common wire must, however, have about 40 per cent. more carrying capacity, since the algebraical sum of the two currents is 1·4 times the strength of each current taken singly. Here you have, then, the theoretical solution of the problem of how to transmit power by alternating currents as indicated by Ferraris, but the first to attack this problem practically was Mr. Tesla, an American electrician, and such motors are therefore also known under the name of Tesla motors, though the name "Ferraris motors" seems to me to be more appropriate, as distinguishing this motor from the two-wire Tesla motors, about which I shall say something presently. To carry out a power transmission by means of such a system, we must have at the generating station an alternator, the armature of which is wound with two circuits giving currents with a quarter-period phase difference, three line wires, and a motor having a laminated field magnet, which is excited by coils placed alternately in the two circuits so as to produce a

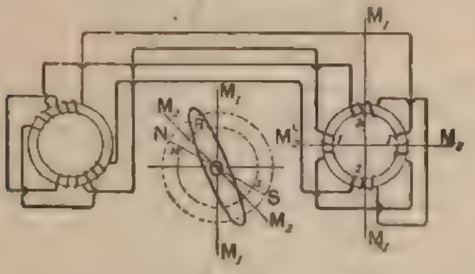

Fig. 10.

revolving field. The armature of this motor must have an iron core, surrounded with coils closed in themselves.

The necessity of using three line wires is, to a certain extent, a disadvantage of this system, and several engineers, Mr. Tesla foremost amongst them, have tried to improve the system in such way that two line wires only should suffice. The methods suggested have this in common, that all aim at producing a difference in phase between the currents passing through the motor, without the use of a second set of coils on the generator. If we insert, for instance, a large inductionless resistance to the branch B, in Fig. 10, and a coil having very little resistance, but great self-induction, into the branch A, the current in the coils 1 1 will lag by a small amount behind the E.M.F. impulses of the generator, whilst the current in the coils 2 2 will lag behind these impulses by a larger amount. The phase difference between the two currents can, of course, not amount to 90deg., which angle is required for producing the best effect, but some difference of phase can certainly be produced in this way. The arrangement will, in fact, be equivalent to that shown in Fig. 12, where the distance between the two sets of coils on the generator is less than 90deg.

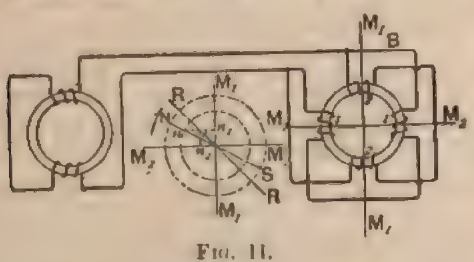

Fig. 11.

An easy geometrical construction, which I need not explain at length, shows that in this case the path of either pole of what I have before called the revolving phantom magnet is an ellipse, but that it can be made to be circular by a dissymmetrical arrangement of the coils on the motor, though in this case the diameter of the circle is much reduced. In either case the value of the machine as a power-producing appliance is also much reduced, whilst at the same time the efficiency must be low, owing to the waste of power in the resistance coil. I can also show you the action of this two-wire motor by means of the mechanical model.

Owing to the low efficiency and small power of the two-wire revolving field motor, its employment is necessarily restricted to cases where these defects are of little consequence, but for the transmission of large powers over long distances it is not suitable. For such a purpose we must have three wires, but this is not a great drawback, since the cost of the line is but little increased by the necessity of splitting up the total weight of copper into three instead of into two wires. The revolving field motor has, however, the defect that it is not self-regulating. Its speed may be anything between zero and that speed which will give synchronism between the two machines accordingly as the mechanical load varies from a maximum to nothing. [illegible] defect can be overcome by combining with the [illegible] the motor a real magnet which will force the armature [illegible] step with the current, and thus ensure a constant [illegible] varying loads. The motor will thus start with great [illegible] virtue of the currents induced in the armature winding [illegible] revolving field, and having reached the synchronising [illegible] will keep there by virtue of the interaction between [illegible] revolving field and the revolving magnet; it will, [illegible] behave just like an ordinary alternator run as a motor [illegible] this difference, however, that the ordinary alternator, [illegible] loaded by 50 or 100 per cent., will be thrown out of [illegible] come to rest, whereas the combined Ferraris and synchr[illegible] motor will always be ready to recover itself after the [illegible] has been removed.

Since the discovery of Ferraris has been made public [illegible] engineers have turned their attention to revolving field [illegible] and especially to a modification of this principle, [illegible] which three sets of coils are employed instead of two [illegible] As far as I have been able to trace the history of this [illegible] the first to suggest the use of three coils were Mr. T[illegible] Charles Bradley. The latter applied in the United [illegible] for a patent in 1888, which bears the number 409,450, [illegible] granted on the 20th August, 1889. Next comes Wenstr[illegible] his British patent, No. 5,423, of 1890, and at about the [illegible] time Dobrovolsky, in Berlin, had worked out a similar sys[illegible]

Fig. 12.

About a year ago, when I visited him at the works of the [illegible] Electrical Company, he showed me such a three-wire [illegible] action, while shortly afterwards Charles Brown, of Oerl[illegible] took the matter up, and it may interest you to learn th[illegible] at the present moment putting up a 500-h.p. transmissi[illegible] on this system between Bulach and Oerlikon, a distance [illegible] 15 miles. This transmission is intended to supply all [illegible] power required in the Oerlikon Works. The general prin[illegible] forming the basis of the work done by these various [illegible] is illustrated in Fig. 13. The generator contains a re[illegible] field magnet, and an armature wound with three distinct [illegible] The end, O, of each coil is joined to a wire, W, common [illegible] and the three free ends are joined with the three line wires [illegible] the receiving station there is a three-legged magnet, the [illegible] the legs being in connection with the line wires on the [illegible] side, and joined by a common wire, W, on the other side. [illegible] is easy to see that the rotation of the field magnet [illegible] generator will produce successive polarities in the legs [illegible] receiving magnet, and that the general effect will be that [illegible] revolving field. The armature, A, will, therefore, be [illegible] rotation, in the same way as is the case in the original Fe[illegible] motor. This kind of transmission is known in Germany [illegible]

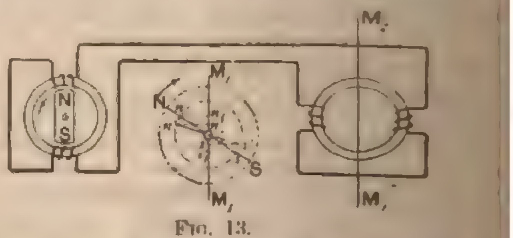

Fig. 13.

the name of transmission by the "three-phase current," [illegible] is likely that it will, ere long, become a strong rival t[illegible] ordinary alternating current.

The diagrams I have brought before you were all draw[illegible] two-pole machines, as this was the simplest way of making [illegible] principles clear; but I need hardly say that, in practice, [illegible] machines are made of the multipolar type, in order to [illegible] the speeds down to any desired value.

You will, perhaps, ask why we should go to the complic[illegible] of three line wires and a totally new type of motor, seeing [illegible] with the ordinary dynamos and motors, such excellent re[illegible] have been obtained, and that with only two line wires. [illegible] answer is that, with this new system, we can greatly exten[illegible] distance of transmission. I have spoken a short time ag[illegible] the difficulties which the high voltage required in long-dis[illegible] transmission, raised in connection with the commutators [illegible] general insulation of machines. Now, in the three[illegible] system of transmission, by alternating currents, we hav[illegible] commutators, and, in fact, not even rubbing currents. On[illegible] our difficulties has, therefore, already vanished. As to [illegible] other, which has reference to the general insulation of machines, it is easy to see how this may be overcome.

y, instead of working direct, work through trans- The insulation of transformers offers no difficulty . I have here on the table a transformer of the type ' Messrs. Johnson and Phillips, which has been specially for high-pressure currents, and is provided nsulation. I have recently used two of these trans- for testing a Brooks line. In one transformer the was raised from 2,400 to 17,000 volts, the high-pressure vas sent through the line, and at the other end it was usformed down to 2,400 volts, and, finally, to 100 volts, ng glow lamps. The apparatus was kept running for lays without any difficulty. Mr. Brown informs me as with oil-insulated transformers, and even gone up to olts, without breaking down the insulation, and the erlikon transmission will be made at 25,000 volts, the machine will work only at a few hundred volts. thus no difficulty in adopting whatever voltage is most al in each case, and yet avoiding all danger, either to dant or to the machines themselves, at the generating r station.

hat I owe an apology for having occupied so much of e with discussing a branch of power transmission which of you must seem to be purely theoretical and hardly iscussion. My excuse must be that I am very strongly l that some form of alternate-current working will be ate solution of the problem how to transmit power— ver all distances, but certainly over very long distances— I was desirous of directing the attention of electrical s to a subject in which much work may still be done.

Electric Machine Tools.

cluding my lectures, I wish to bring before you a few of short-distance transmission as applied to electric tools. This branch of our subject has of late years considerable development at the hands of various irms, and, thanks to their enterprise and perseverance, well-established method in several engineering works. xample I may mention the Leven Shipyard of Messrs. ros., at Dumbarton, and Mr. Archibald Denny has been igh to give me some particulars of the work carried on m in this direction. I cannot do better than quote his "In our yard and engine works we have numerous of electric transmission of power. In our experimental drive our model cutting machine and small lathes by a 3-h.p. Immisch motor. In our upholstery depart- drive six sewing machines with a 2-h.p. Immisch f course, in this case there is a large margin of power. xperimental tank we have also used small motors for mall model paddle wheels in our experimental models, obtained in this way most valuable data, which we have got by any other means. The power for all this obtained from a dynamo driven by an ordinary line of in our joiner's shop. We also use a 3-h.p. motor in the boring the stern tubes in place. Before this we used a engine, which necessitated an attendant to fire the d carry water to it."

ng the holidays, when all the boilers are off except one, onally put down a motor for driving some lathes to do ork, and this saves an attendant at more than one In our engine works the pattern-shop is driven by a lanchester motor, the dynamo being driven off the line g in the fitting shop."

e, Messrs. Denny Bros. find electric power transmis- handy, economical, and convenient, that they make use of it. They employ a special tool for drilling the s of engines, which I now show on the screen. The ' the machine is sufficient for the pressure required on and the whole apparatus being mounted on wheels, it rapidly shifted. The machine will drill 1¼in. holes two thicknesses of inch plate in three minutes.

r machine used at Leven Shipyard is a special drill for ps. The motor and gear are mounted on a stout olumn with horizontal arm, so as to give adjustment in ctions, the column being bolted to the strap, as shown. hine will take in straps 50in. deep by 23in. between s of holes, and is chiefly used for drilling sheer strake utt straps. The outside strap is first punched and nk, and the machine drills through the plate and ap. The machine is worked by two men—one hole- l one labourer—and will do three straps, or about 180 day.

vet holes in boiler furnaces are also drilled by an ool, which I illustrate on the screen. The machine od stand arranged to go inside the furnace, but it has ng-on magnets for outside work. One man with this does the work which formerly required three to four

ount of electric machine tools would be complete if it nclude the work done by Mr. Rowan, who has been essful in developing this branch of power transmission. the improvements Mr. Rowan introduced is that of n magnets, whereby the tools are firmly held in place while at work, and yet by the mere turning of a switch become liberated, and can be shifted to a new position with the greatest ease. You see on the screen some of Mr. Rowland's drillers as applied to ship work. The apparatus is suspended on a chain over the ship's side, and supplied with current by means of two flexible wires. I need not detain you with a description of the picture on the screen, because I can show you the actual machine at work, thanks to the kindness of Messrs. M'Whirter, Fergusson, and Co., the makers, who have sent me one of their latest machines for this lecture.

I am also indebted to Mr. Webb, the locomotive superintendent of the London and North-Western Railway, for the loan of one of his electric tube cutters, which you see before you, and which I shall now work. A diagram of this machine to an enlarged scale is on the wall.

These few examples of what are properly called electric machine tools must suffice for this lecture, but there is another class of apparatus—namely, electric mining machines, which ought to be included in our subject. Several firms, both here and abroad, have of late years devoted considerable attention to the application of electric power to mining operations, such as pumping, hauling, coal-cutting, and drilling. Messrs. Goolden and Co., for instance, have during the last four years steadily and perseveringly worked out many of the difficult problems in connection with this subject, and I am indebted to this firm for the loan of the apparatus you see here, and also to Mr. Atkinson for assisting me in setting the machines up. After the excellent paper which Mr. Atkinson read at the Institution of Civil engineers, only a few weeks ago, it would be occupying your time uselessly if I were to give any lengthy description of these machines. I shall, therefore, merely show two types of mining motor on the screen and show you a drill at work.

I have in these lectures not attempted to treat exhaustively any one branch of the subject, but have rather endeavoured to pass the various branches in rapid review, so that you may know what electric transmission of power can do and what it cannot do. We hear nowadays very frequently the assertion that electricity is but in its infancy, and will ere long be the sole motive power, driving our main-line trains, speeding our vessels across the ocean, and running our factories. These are idle dreams, ideas put forward by persons who have forgotten or have never learned the fundamental laws of nature. Do not waste time over such ideas, for there are other more hopeful problems, such as the utilisation of water power generally, of waste coal at the pit's mouth, the working of railways in mountainous districts, where water power is abundant all along the line, the working of tramways, underground town railways, the application of electric power to such purposes for which now small auxiliary steam engines are employed, and last, but not least, its application to machine tools and other special machinery, of which I have given you examples to-night.

COMPANIES' MEETINGS.

CITY AND SOUTH LONDON RAILWAY COMPANY.

Directors: Charles Grey Mott, Esq., Chairman, Harrow Weald Lodge, Stanmore; Charles Seymour Grenfell, Esq., Elibank, Taplow; Sampson Hanbury, Esq., Langford Park, Maldon, Essex; S. Barclay Heward, Esq., 57, Old Broad-street, London, E.C.; Alexander Hubbard, Esq., Derwentwater House, Acton.

Report and accounts for the half-year ending June 30, 1891, submitted to the half-yearly ordinary general meeting, held on August 11:

In presenting their report and statement of accounts for the half-year ended June 30, 1891, the Directors have to report, with satisfaction, that the railway has been worked during that period without accident to any passenger, or to any of the staff employed. Although occasional delays to the traffic have occurred through defects in the rolling stock or other similar causes, these were at first to be expected during the working of a new and untried system of locomotion, and it is a matter for congratulation that in all these cases the delay has been of very short duration, and the regularity of the working is steadily improving. The receipts during the half-year from all sources amount to £19,688. 2s. 4d., and the expenses for the same period to £15,520. 16s. 5d., leaving a net profit of £4,167. 5s. 11d. The net revenue account shows a balance of £4,693. 3s. 8d., of which amount the interest on debentures absorbs £4,137. 16s. 6d., leaving a balance of £555. 7s. 2d. to be carried forward to the next account. In the beginning of a new undertaking many of the items of expenditure are necessarily high, but your Directors have satisfaction in stating that some of these have already been considerably reduced, and further reductions will from time to time be made, so far as is consistent with the safety of the public and the interests of the Company. During the half-year the number of passengers carried by the railway has been 2,412,343. For a considerable time a uniform charge of 2d. for passengers was adhered to, but it has been found necessary in order to compete with the omnibus and tramway traffic to reduce the charge at certain stations to 1d. during stated hours. This has been found to work advantageously, both in the Company's interest and to the convenience of the public. Two additional locomo-

tives are now nearly ready, and one train of the new carriages has already been received. The completion of these, and the additional generating engine and dynamo now in course of construction, will allow of a considerable increase in the train service. The action taken by the London County Council in November last to contest the right of the Company with respect to the line of frontage at Kennington and the Oval stations has been decided in favour of the Company by the Court of Appeal. The Bill promoted by the Company in Parliament for an extension of the line to Islington failed to pass the Committee of the House of Commons, and the Directors regret that a valuable aid to the traffic of the existing line, and a great accommodation to the public, has been in consequence delayed. Your Directors regret that owing to other engagements Mr. Walter Robinson has decided to resign his seat at the Board, and the vacancy so created has been filled by the election of Mr. S. Barclay Heward, of 57, Old Broad-street, London.

The fourteenth ordinary general meeting was held at Winchester House on Tuesday, Mr. Charles Grey Mott, chairman, presiding.

The report having been taken as read, the **Chairman** said there was one matter connected with the report which he was sure they would have read with satisfaction, and that was that they had been enabled to carry two millions and a half of people during the half-year to which it referred without any accident whatever on the line. He regretted that a few days ago for the first time in the history of that Company a fatal accident occurred, but as the passenger in that case acted in violation of the by-laws of the Company and in direct defiance of its officers, no blame could attach to the Company in the matter. At the same time his hearers might be sure that they (the Board) regretted such an accident exceedingly and sympathised very much with the relatives of the passenger who was unfortunately killed. The past half-year, as they could well imagine, had been a very anxious one to the Board. In the first working of a new system such as that, three points were naturally presented to the Directors of a Company situated as that was. First, would the system of electric locomotion work at all? Secondly, would it work satisfactorily; and thirdly, would it work in such a way as to give a remunerative return to the shareholders for the money invested. On the first two heads the Board could report with confidence in the affirmative. They had worked the railway, and they had worked it satisfactorily. As regarded the last head, he was sorry to say that at present they could not answer with the same satisfaction. They had yet, at some future time, to say that that system was not only efficient, but one that would be a fairly financial success. As they had seen from the accounts, the past half-year had given them a profit which had enabled them to pay their debenture interest in full, and had left a very slight margin beyond. As they had no other preference charges at present beyond the debenture interest, and beyond a very small sum that they might have to pay for the preference shares that might be issued—which, as they knew, was a very small amount indeed—any further profits would go into the hands of the ordinary shareholders. He hoped that the future profits of the line would go on steadily increasing, and that it would not be so very long before he might have the pleasure of standing there and feeling that they had earned a substantial dividend. But that rested with the future, and he did not like to prophesy on these points. They knew he had always refused to do so, and he thought, wisely. He preferred to deal with accomplished facts rather than with any roseate views which might or might not be fulfilled. They might like to have a short *resumé* of their present financial position. The receipts from passengers during the past half-year—and they were the only source of receipts they had at present, because they had practically no other traffic over the line but passenger traffic—had amounted in the whole to £19,403. They had received a small sum from transfer fees, rents, and so on, which brought the total up to £19,637. 10s. 3d. They had earned that by carrying 2,412,343 passengers. The number of passengers per train mile run was 17. If that were an ordinary railway, this would be a very large number; because the general average of the large English railways was only about $3\frac{1}{2}$, the general average of all the lines, including suburban ones, in this country being about five. But, then, their's was a purely metropolitan line, costing very much more, and the traffic upon which was expected to be very much heavier than that of the ordinary railways of the country. They might ask—was their capacity for carrying the traffic utilised to its maximum point? No! With their present train service they could carry three times the present number of passengers if they were spread over the 24 hours. Therefore, they had capabilities of development, even upon their present system of working. Before long they would be running more trains, and if the traffic grew they would be able to take a very much larger number of passengers than they could now. Their earnings per train mile had been 2s. 9d. Of course, the earnings per train mile on a line of this kind ought to be larger than those of the ordinary railways. Unfortunately, at present, they were not, because they were not carrying the relative amount of traffic to those railways which they ought to do. The average passenger receipts on the London and North-Western per train mile were 3s. 3d. Some lines earned more. All the large railways benefited, however, from receipts from other things carried per passenger train, such as parcels, horses, carriages, mails, etc. Their expenses were, as stated in the report, heavier for the past half-year than the present rate of expenses at which they were now working. In the early stages of the system it was necessary that they should have a very large staff to deal with a traffic which was unknown and new. They had also to ha[illegible] sive men to educate the staff. The reduction in the rate [illegible] diture was one of the pleasant features of the future. T[illegible] of course, yet to learn the cost of maintenance of [illegible] stock which was new now. But he did not think it was lik[illegible] out that they would have a very heavy item of mainten[illegible] their experience so far. Their permanent way expense[illegible] likely to be so high as those of an ordinary railway. T[illegible] motive power was at present a point which compared un[illegible] with the ordinary working of a steam railway. But he [illegible] ture to caution them against taking the amount in the[illegible] as a permanent and absolutely ascertained figure. It ha[illegible] difficult, especially in the first half of the year, to [illegible] permanent charge for steam engine power, because th[illegible] was used for several purposes besides working the l[illegible] and absolute division of the charges was difficult; [illegible] estimated rather than ascertained. In the future he [illegible] have them settled, and that they would be able to de[illegible] accurately with this account another year than they [illegible] The expense of running a train mile had been about 11[illegible] steam this charge varied from about $9\frac{1}{2}$d. to 1s., so [illegible] might be said to be not far from on a par with steam [illegible] this matter. Of course, however, their (the City and South[illegible] trains were very much lighter, and would not carry [illegible] passengers as the other lines. But as they carried a[illegible] passengers at present as they had to carry—the[illegible] none away they were not losing anything by [illegible] smaller trains, and he was not sure but that [illegible] future the system of having light trains run more fre[illegible] would in the end prove more economical and more cond[illegible] the public comfort than running so many comparatively [illegible] trains, as was done on an ordinary railway. They had [illegible] contend in this first half-year with a good many difficulties[illegible] they were steadily trying to overcome them. They wer[illegible] serious, but the small improvements which they were making [illegible] hoped to make, would, he thought, render the railway much [illegible] popular in the future than it had been in the past. At the [illegible] time he thought that anyone who had used the ra[illegible] would feel that as far as comfort, speed, and all [illegible] general accessories of convenient railway travelling [illegible] concerned, their line was not inferior to that of any [illegible] ordinary steam railways. They hoped in the future to [illegible] it very much superior, and that when all their improvements [illegible] carried into effect it would be confessed that they had initiated [illegible] brought into use a system of locomotion decidedly superior t[illegible] in existence. The great stage coaches of the past had the[illegible] which lasted for some 60 years. They were superseded by [illegible] railways, which had lasted up to the present time for a[illegible] 60 years, that was, had had their day. It remained to be p[illegible] whether electricity was the mode of locomotion that would s[illegible] sede steam. At all events, they had the satisfaction of kno[illegible] that they had tried to do something towards its development[illegible] he hoped it would not only prove a success as far a[illegible] public convenience was concerned; but that the time [illegible] come when he would be able to congratulate the[illegible] its financial success also. They were making improvem[illegible] various directions. They had had new carriages built, [illegible] new trains of them, and they were now on the ground [illegible] being put together ready for working. He thought they [illegible] be felt to be a decided improvement on the other ones. Two [illegible] locomotives were building, which they also believed would [illegible] the speed and regularity of the trains. Special attention was [illegible] paid to the lighting of the latter by electricity. One half of [illegible] were now lighted on an improved principle, which woul[illegible] thought, be still further developed. Hitherto the electric [illegible] had been uncertain, but he thought they were making it c[illegible] and that it would be thoroughly satisfactory for the purpose. [illegible] had just fixed two new boilers in position, so as to give [illegible] additional power. They had a new engine and dynamo nearly [illegible] for delivery, and before long they would be in a position to cope [illegible] the traffic which came to them (as unfortunately all sub[illegible] traffic did come) in an irregular manner. In the morning [illegible] evening there was a sudden rush of people, and in the mid[illegible] the day hardly any passengers to carry. They hoped to get [illegible] increased traffic first by disabusing the public mind of the [illegible] dice which very largely existed at present against travelling [illegible] underground railway of that description. When the Metrop[illegible] Railway was first opened they would recollect how very [illegible] was the prejudice against it. People had got over [illegible] but, of course, with a railway (such as the City and [illegible] London) which was two stories underground, and w[illegible] by a power so little known as electricity, there was a [illegible] deal of public prejudice to be overcome. He believed [illegible] would overcome it when they had everything in w[illegible] order, and that the traffic would steadily increase. They [illegible] to get, and were getting, an increase of traffic from the gro[illegible] population on the route. Houses were being occupied alon[illegible] line, and new houses were being built, and naturally there [illegible] be a growth of the population. All railway companies found [illegible] increased facilities for traffic produced increased traffic, a[illegible] the expenses of their line would not, he thought, grow in the [illegible] proportion as they did upon an ordinary steam railway, they [illegible] some hope for the future, though, unfortunately, it was [illegible] deferred at present. One of the most important questions [illegible] had to consider was how to fill up the trains during the ce[illegible] the day. They had made an effort to do this during the la[illegible] or three months, by reducing the fares from 2d. to [illegible] certain stations and at certain stated times. The [illegible] had been so far satisfactory, that it had resulted in their ca[illegible] from those stations during those times three times the traffic

ried before, and their receipts increased from these stations me 50 per cent. Whether the development of this policy—creasing the fares at other stations—would produce like results s a question they had to consider very carefully. It was not the interests of the Company to reduce fares. They regretted have to alter the plan of a perfect uniformity of fare over the e. They thought they should adjust their ideas to the circumances of the time, however, and increase the popularity of the e and its resultant receipts. They agreed to go to Parliament an extension of that line from the City up to The Angel at Islingn. That would have been a very good line in itself, and would, thought, have paid very well, as well as bringing to the existing e a very considerable increase of traffic exactly at the time of y they wanted it. Unfortunately circumstances occurred in the at Committee of the House of Commons which led them to row out the Bill. There was very slight opposition, the only maining opponents at last being the Corporation of London, and en they, he believed, did not wish that the Bill should be thrown t. They (the Board) had nothing to do with the circumstances ich arose. It was very doubtful whether in their present ancial position the Board would come to the shareholders again th a recommendation to go for that extension, because until ey had brought up the price of their shares in the market, it as doubtful whether they could obtain the necessary capital. tween this and next session they would have to consider the estion, and if they could see their way to carry it out thout burdening the existing company, they would prefer to so. The new plant they were putting down was intended as rt of that which would ultimately work the Clapham extension, t the same reason which prevented their going for the Islington e applied to the Clapham one. They would see from the report at the action taken by the County Council—which was a very bitrary one on the part of that Council, who really had no good se as regarded that Company, the real object being the testing particular rates which they thought they could try upon a small mpany better than a large one—had been successfully opposed the Company in the first courts, and the result affirmed in their vour in the Appeal Court. Having nothing further to add, he uld move that the report and accounts be approved and opted.

This was seconded by **Mr. Hanbury**.

Mr. Poto was glad to hear the Chairman say they were not ing to proceed with the Islington extension. They would not e anything by waiting to see what would be the result of working e old line. He noticed that they had elected another gentleman the Board in the place of Mr. Robinson, resigned. He asked, oking at the fact that the railway was a very small matter, was absolutely necessary to have five directors? He did not want em to work for nothing, but it seemed to him that three would ample. Adverting to the wages and salaries, he asked whether e work of manager and secretary could not be done by one ntleman.

The **Chairman** said that, unfortunately, they were bound by eir Act of Parliament to have five directors, and, moreover, ey could not do with less, as three formed a quorum. Though e income of the Company looked small at present, the work concted with it was by no means small. This was a railway that quired a very great deal of constant attention and management. ey could not do without an efficient staff at their headquarters. ey must remember that the number of passengers carried was ry large, and the number of trains and the length of time they re run exceptionally so. They were therefore obliged to duplite the staff in many cases. The latter was therefore necessarily ger than was absolutely proportionate to the traffic. The lative expenses on this head would diminish as the traffic creased, because it would not be necessary to increase the staff. to the appointment of Mr. Howard as Director in place of Mr. obinson, that gentleman represented very large shareholding terests in the Company, and had given them the benefit of his vice at the Board for a long time, and had acquired considerable owledge of the Company's affairs. They thought, therefore, ey could not do better than ask him to take a seat at the Board. e Chairman then put the resolution, which was carried unaniously.

The proceedings closed with the usual vote of thanks to the airman.

LIVERPOOL OVERHEAD RAILWAY COMPANY.

The half-yearly meeting of this Company was held in Liverpool Tuesday, Sir Wm. B. Forwood presiding. The report is uded to in our "Notes."

The **Chairman** referred to the progress of the works during the st half-year, and said he was pleased to say that they had made isfactory progress indeed. The main structure had advanced ath to the Collingwood Dock, in the course of which three portant opening bridges had been constructed. The foundations re completed as far south as St. Nicholas Church, and they pected the main structure would be advanced to that point by e end of September or the beginning of October. During the st six months they had erected two miles of the main structure, d the contractor expected that the whole of the foundation for e southern section would be completed within four months. It s somewhat rash to hazard an opinion as to when it would be mpleted, but he hoped that the forecast which he gave at the t meeting would be realised, and that when the shareholders met ain next spring they would be within measurable distance of the mpletion of their important undertaking. The position of the line the southern section would be changed somewhat from what it s originally proposed to be. The original plan was to elevate it along the Wapping Dock and warehouses, but by the liberality of the Corporation of Liverpool and the Dock Board they would now be able to keep on the same level all through. That was very important for the successful working of the railway. During the past six months the Directors had given serious consideration to the means of propulsion to be employed, and they had visited various electrical works in the country, including the electric railway now working in London. They had had the advantage of the advice of Mr. Greathead, the engineer of the railway running under the Thames, and after carefully considering the subject, they had decided to adopt electricity, because it would be safer, cleaner, and more economical in its working. Tenders were then invited from the principal manufacturers of electrical machinery, and the Directors had accepted the tender of the Electric Construction Corporation, of Wolverhampton. The electricity would be generated at a central station, to be located near the Wellington Dock, a position which they had been fortunate enough to obtain from the Dock Board. By having their station at that point they could obtain water at an advantage, and they would also have the advantage of having their coal tipped from the railway overhead, without the necessity of constructing buildings, etc. In that way they would save a considerable amount of money. The electricity would be conveyed by a central rail to the motor cars which will compose the train. The journey from end to end, including stoppages, would be made in 25 minutes. In order to safeguard the shareholders as much as possible from the many contingencies which beset railways, a contract was made with the Electric Construction Corporation for working the train at a fixed price per train mile for two years. That in itself was a guarantee that they would work it safely, and at the same time give the best possible machinery. He was sure they would be gratified at the progress of the works. They had had their difficulties, but he was glad to be able to say that these had been surmounted, and now he hoped that there would be no further obstacle to the work progressing with great rapidity, and he really thought that at the next meeting of the shareholders they would be within very near distance of the completion of the railway. With these remarks he begged to move the adoption of the report.

Mr. J. B. Brancker seconded the motion, and it was carried unanimously.

Replying to various questions, the **Chairman** said that the main structure had now been advanced to the Clarence Dock, and the Company had decided to have first and second classes. Fares had not yet been resolved upon. The 3½d. per train mile covered the whole of what were known as the locomotive expenses of the line. It had been the intention of the Directors from the first to open the northern section as soon as it was completed; but a great deal would depend upon the completion of their electrical plant and generating station. In other words, the southern section was being proceeded with so rapidly that it might be completed by the time the electrical equipment was ready, and in that case all sections of the line would be opened together. The Directors did not at present contemplate manufacturing electricity for illuminating purposes, except for their own uses. The line would be lighted by electricity manufactured by themselves, but if they went beyond that they would require a far larger area for generating plant, and they must bring their own business to a state of efficiency before they attempted anything in that direction.

UNITED RIVER PLATE TELEPHONE COMPANY.

The fifth ordinary general meeting of this Company was held on Friday, 7th inst., at Winchester House, Mr. J. Irving Courtenay presiding.

The **Chairman** said the results of the past year's working of the Company had been entirely governed by one factor—the gold premium. The gross income for the past financial year had been £106,259, as compared with £108,612 in the previous year, the difference arising solely from the diminution of their sales business, which, in consideration of the long credits customary in the River Plate, they had not thought it prudent to push. More money had been received from subscribers and messages in the year under review than in the previous year, although there had been a considerable falling off in the total number of their subscribers. No fewer than 1,089 new subscribers came on their books during last year, and he believed they would find their experience to be the same as had been found in other enterprises—that the subscribers who came on during a period of financial tightness were more permanent subscribers and were better payers than those who came on during a period of inflated commercial prosperity. Their working expenses in the River Plate had been £56,941, a reduction of £6,566 compared with those of the previous year. This reduction of 10 per cent. had been the result of economies, notwithstanding the increased cost, to a considerable extent, of materials, general expenses, and taxes. Further economies to some extent were anticipated, but unless a reduction occurred in the gold premium a greater degree of expenditure must be expected. This would necessitate such a rise in their rates as would at least meet the increased expenditure. He regretted that the Directors were unable, for the first time in the Company's history, to declare a dividend. This was entirely owing to their loss on exchange, which had amounted to £36,049, or nearly 12½ per cent. on the Company's paid-up capital. With only a slight revival of commercial affairs in Buenos Ayres and a fall in the gold premium, the Company would soon again be in a dividend-paying condition. Telegraphic advices from Buenos Ayres, dated the 4th inst., stated that their receipts for July had been better than those for the same month of last year. The report and accounts were adopted.

CUBA SUBMARINE TELEGRAPH COMPANY.

The fortieth ordinary general meeting of this Company was held on Wednesday at the offices, 58, Old Broad street.

Mr. Thomas Greenwood presided, and stated that the receipts for the half year to June 30 last were not so large as those for the corresponding period of the previous year. This had been owing not to any want of trade, but to the impediments caused by the breaking down of one of their cables. As, however, they now had their cables duplicated from end to end, it was highly improbable that such a circumstance would occur again, and therefore they might look to their revenue continuing. The repairs had been completed during the half-year, and the charge had been rather less than in the June half of 1890, the result being that they had rather a larger sum to carry to the credit of the reserve fund. That fund now amounted to £78,000. They had expended about £22,500 on new cable, and, therefore, but for this outlay, which really was properly invested for use, their reserve fund would amount now to rather over £100,000. The suit with the Spanish Government made slow progress; and he could not say when the case would come on for hearing. The delay was not very prejudicial to them—in fact, all that they wanted was that there might be perpetual delay. They wanted a decision that the Government had not the right to grant the concession which they opposed, and, until this matter was decided against the Company, they were going on with their business, and their opponents could do nothing. He concluded by moving the adoption of the report and accounts, which was seconded by **Mr. A. F. Low**, and carried unanimously.

Dividends for the half-year at the rate of 10 per cent. per annum, subject to income tax, on the preference shares, and at the rate of 8 per cent. per annum, free of income tax, on the ordinary shares, were declared.

MONTEVIDEAN AND BRAZILIAN TELEGRAPH COMPANY.

A general meeting of this Company was held on Tuesday at the offices, Copthall-avenue, when the report and cash account of the liquidator, Mr. George Fraser, were approved and adopted.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts for last week amounted to £4,243.

Western and Brazilian Telegraph Company.—The traffic receipts for the week ending July 31 were £2,696.

City and South London Railway.—The receipts for the week ended the 8th inst were £821, against £692 for the week ending August 1.

Western Counties Telephone Company.—The half-yearly warrants for dividend to June 30 last, on the preference shares of this Company at the rate of 6 per cent. per annum were posted on Saturday the 8th inst.

NEW COMPANIES REGISTERED.

Energy Gas, Electric Lighting and Power Company, Limited. Registered by A. Herbelet, 5, Chancery-lane, W.C., with a capital of £20,000 in £1 shares. Object: to acquire certain patents relating to gas lighting, and to develop and work the same; to carry on the business of mechanical engineers, etc. Registered without articles of association.

PROVISIONAL PATENTS, 1891.

AUGUST 4.

13163. **Improvements in carbon transmitters for telephonic purposes.** William Blenheim, Egham, Surrey.

13171. **An improved socket for incandescent electric lamps.** John Criggal, James Berkley, and Charles Frederick Williamson, 34, Southampton buildings, London. (Complete specification.)

13200. **Improvements in fence posts, telegraph posts, or the like.** George Cecil Dymond, 6, Lord-street, Liverpool. (Frederick Peter Rosback and Henry Frederick Band, United States.) (Complete specification.)

13208. **Improvements in the manufacture of wire, bars, bands, and sheets of copper by electrolysis, and in apparatus therefor.** Edward Casper, 4, South-street, Finsbury. (Emile Viarengo, Italy.)

AUGUST 5.

13250. **Improvements in electrical switches and safety fuses.** William Humphrey Wheatley, 40, Chancery-lane, London. (Alfred Ashfalck, Germany.)

13252. **Improvements in electrical contact making and breaking devices.** Charles Fery and Eugene Ducretet, 45, Southampton-buildings, London.

13268. **Improvements in ele[illegible] alarms.** William Wilson [illegible] 151, S[illegible] (Brunswick W[illegible] Leonard [illegible]. N[illegible] [illegible]tes.)

13269. **An improvement in connecting the conductors [illegible] trical glow lamps.** Edward Alfred [illegible] Southampton-buildings, London. (Complete spec[illegible]

AUGUST 6.

13274. **Improvements in electric meters.** Pares Eugene [illegible] 6, Victoria road, Kensington, London.

13280. **Improvements in electrical conduits and con[illegible]** John Mackintosh Mackay Munro, 154, St. Vince[illegible] Glasgow.

13315. **Improvements in arc lamps.** James Yate Joh[illegible] Lincoln's-inn-fields, London. (Charles Bellens, [illegible] (Complete specification.)

13331. **Improvements in telephony, and apparatus th[illegible]** Milo Gifford Kellogg, 24, Southampton-buildings, Lo[illegible]

AUGUST 7.

13335. **Electric tell tale for the control of mast head [illegible] and side lights on steamers.** Leon Harry [illegible] Crowle-street, Hedon-road, Hull.

13362. **Improvements in dynamo-electric machines.** [illegible] Forbes, 34, Great George-street, Westminster, Lond[illegible]

13366. **Improved telephone transmitter.** John Dunham [illegible] 31, Lombard-street, London.

13367. **Improvements in electric telephone switch[illegible] systems.** Thomas Beaven Sloper, 323, High [illegible] London.

13371. **Improved electro manual devices for the actu[illegible] gravity signal arms, points, and the like.** [illegible] Harington Leigh, 22, Southampton-buildings, L[illegible] (A. Hillairet and Albert Hugnet, France.) ([illegible] specification.)

13372. **An improved electric or galvanic brush.** Arthur [illegible] Byng, 55, Chancery-lane, London.

13384. **Improvements in electrical contacts.** George [illegible] 24, Southampton-buildings, London.

13387. **Improvements in dynamo-electric generators.** Henry Cazal, 40, Chancery-lane, London.

AUGUST 8.

13437. **An improved method of and means for electric[illegible] munication between parts of railway trains.** [illegible] James Howes, 11, Furnival street, London.

13442. **An improved wave power motor.** William Wils[illegible] 151, Strand, London. (Henry P. Holland and [illegible] Fischer, United States.)

13446. **An improvement in secondary voltaic batteries.** [illegible] Joseph Starkey Barber-Starkey, 28, Southampton bu[illegible] London.

13460. **Improvements relating to the coating of articles [illegible] new metallic alloy by electro deposition.** The [illegible] Metallurgical Company, Limited, and Sherard [illegible] Cowper-Coles, 45, Southampton-buildings, London.

SPECIFICATIONS PUBLISHED.

1890.

11065. **Impregnating organic, etc., matter by an [illegible] current.** Oncken. 8d.

12832. **Electrical meter.** Wilson 8d.

14404. **Electrical switches.** Snell. 8d.

14411. **Secondary batteries.** Niblett. 8d.

14484. **Electric switch, etc.** Evered and Rudling. 8d

14696. **Telegraphic relay.** Bayly (Treber) 8d.

14698. **Electrical conductors.** Crompton and Chamen [illegible]

14830. **Accommodating electric wires in buildings.** Wal[illegible]

16279. **Electrical casting of metals.** Slawianoff. 8d

18908. **Magneto-electric telephone apparatus.** Fraser [illegible]

19749. **Electric lamps.** Turner. 8d.

20329. **Electrical transformers.** Woakes. 6d.

1891.

7353. **Electric railway systems.** Bayly (Weems). 8d

10227. **Electrical conductor.** Holmes. 4d.

NOTES.

Portraits.—The *Electrical World* for August 8 contains a speaking likeness of Mr. W. M. Mordey.

Omagh.—The Town Commissioners of Omagh are desirous of having particulars of the cost of lighting the town by electricity.

Power from Niagara.—It is proposed to transmit power electrically all the way from Niagara Falls to the forthcoming Chicago Exhibition.

Lisburn (Ireland).—The gas company of Lisburn have advanced the price of public lighting. The authorities are considering the question of electric light.

Fleetwood.—At the last meeting of the Fleetwood Improvement Commissioners the correspondence upon electric lighting was left over till next meeting.

Chertsey.—The gas lighting of Chertsey has been settled for this year at £3. 3s. per lamp. The question of considerable extension to Addlestone is to be considered next year.

Telephone at Clitheroe.—The Clitheroe Watch Committee refused to take any part in the connection of the police office with the workhouse by telephone as proposed by the Board of Guardians.

Nomenclature.—Confusion—we mean no joke—is often experienced between a fuse and a fuse; that is, between a fusible strip, and a box with terminals to contain it. It is proposed to call the former "fuse links."

Sophia.—Premiums of 10,000, 7,000, and 5,000 francs will be awarded by the authorities of Sophia for schemes of lighting that town, the said schemes to remain the property of the town. The plans will be opened on 28th December, 1891.

Felstead School.—A complete installation is being erected for the lighting of Felstead School by Messrs. Drake and Gorham. The lighting is being extended, not only to the school, but to the chapel, gymnasium, infirmary, and other outbuildings.

Brazil.—A sample electric railway installation has been sent to Brazil from the United States, consisting of one car with 25-h.p. motors, a 50,000 watt generator, and entire equipment for a 1½-mile track. If successful, complete plant for 60 cars will be required.

Bewdley.—The Bewdley Watch and Lighting Committee reported that the offer of the gas company to light the public lamps for the eight months from September 1st at £2. 10s. a lamp had not been accepted by the committee, which hoped to make more favourable terms.

Electric Advertising.—The whitewashed walls of tunnels are used in Chicago in a novel advertisement. On the centre of the roof is a wire placard, arranged in such a way that the glare from the electric light casts huge shadowed letters on the wall. Enterprising advertisers may note.

Central Station Arrangement.—We notice that a work on central stations, by M. G. P. Anney, entitled "Manuel Pratique de l'Installation de la Lumière Electrique, Stations Centrales," has been published in Paris (B. Tignol, 53, Quai des Grands Augustins, Paris, 7f.), with 99 figures and 10 plates.

Lynton.—The Devon Electric Lighting Company intend to apply to the Board of Trade for a provisional order to supply electric lighting to Lynton and Lynmouth. The application will be made in November. Ventilation shafts have been affixed to the present electric lighting plant, and other improvements are being made.

Electric Lighting in Ireland.—The seaport of Larne has been lighted by electricity. This is the first town in the North of Ireland which has adopted the new light. This installation, like that of Carlow, has been carried out by Messrs. J. E. H. Gordon and Co.

Dover.—At the last meeting of the Managing Committee of the Dover Town Council, a letter was read from the Brush Company, stating that the letter of the Council's *re* electric light was under consideration, but that time was required to give a satisfactory answer; and also that one of the company's engineers was about to visit Dover and report.

Bahia.—We notice that the *Moniteur Industriel* (Aug. 13) gives particulars of a contract invited by the State of Bahia, Brazil, for public lighting—no system mentioned—from the 9th May, 1892, the contract with the Bahia Gas Company expiring at this date. The contracts are to be in the hands of the secretary, Manoel Pedro de Rezende, Bahia, by 30th of this month.

Alternate-Current Motors.—Readers of the patents column may see that two specifications were accepted last week for alternate-current motors, one being the complete specification of Dolivo-Dobrowolski, and the other a motor invented by Mr. Arthur Arnot, of Australia, which we mentioned a few weeks ago. There is also an improved generator for multi-phase currents.

Sydenham.—A new company has been brought out this week, the Electric Installation and Maintenance Company, for the supply of electricity to the Crystal Palace and the district of Sydenham. The capital is £100,000 in £10 shares, of which Messrs. J. E. H. Gordon and Co., who are contractors to the company, are to take over a thousand as part payment of plant.

Liverpool.—The Liverpool Electric Company have objected to certain charges made by the Liverpool Corporation for the repair of roads. It was stated at the meeting of the Health Committee that the Corporation were on the safe side, as the company had deposited £500, from which the amount could be deducted. If a dispute arose, the Board of Trade would arbitrate.

Barnsley.—At the last meeting of the Barnsley Town Council, the minutes were read of the Park and Lighting Committee meeting held July 31. The borough surveyor laid before the committee a scheme and plan prepared by him for the supply of electricity to a smaller area than the one referred to in the Barnsley Electric Lighting Order, and the committee adjourned the consideration thereof until their next meeting. The minutes were confirmed.

Glasgow.—At the Glasgow Town Council meeting last week, it was stated that at the meeting of the Gas Committee it was decided to take the advice of Sir William Thomson with regard to various matters which had recently cropped up, and which were of vital importance to the question of the electric lighting of Glasgow. Under the circumstances, Councillor Colquhoun agreed to delay for a month the motion standing in his name with reference to electric light.

Collodion in Electroplating.—In a recent patent, Herr Falk, of Berlin, claims the use of photographic collodion as a conducting layer to be applied upon the body to be plated. After drying and exposing to the light the silver salts are reduced by the sulphate of iron, and produces a metallic surface. This process is often described in lectures on physics, and has been employed more particularly, it is said, for some time back to the plating of flowers and insects.

Electric Cure for Sciatica.—A correspondent of a medical paper says that if the positive pole of a galvanic

battery having the pole (carbon preferred) covered with absorbent cotton and moistened with chloroform be put over the parts suffering from sciataca, and five to 10 milliamperes of current passed through it every other day for a short time, a cure will be effected, providing there is no constitutional trouble. The negative pole can be applied at any suitable place.

Storage Cars in America.—Storage cars will soon be again seen in New York. The recent decision as regards the Brush patents is responsible for this action, and, in addition to the 16 cars formerly used, it is stated that the whole of the Fourth-avenue route will be equipped by accumulator cars. Washington is to have 44 such cars at once, and Indianapolis and New Orleans are to have trial systems. A battery system is also to be established at Newton, Massachusetts.

A Theatre Struck by Lightning.—At Grosswardein, in Hungary, on Monday, a flash of lightning struck the theatre during a performance. The audience, believing the house had taken fire, rushed to the doors, the consequence being that a number of women fainted and fell under the feet of those in the rear. Happily, some of the more cool-minded among the audience were able to reassure the crowd, and no serious injury was done. The performance, however, could not be continued.

Death of an Australian Electrical Engineer.—Mr. Henry E. Dickenson, of Sydney, met a sad death when attending to the electrical machinery at the Australia Hotel, Sydney. He accidentally fell off the stage, striking his head against some ironwork. Mr. Dickenson was recently elected secretary to the Engineering Association of New South Wales. Previous to his appointment as engineer-in-chief to the Australia Hotel, he was engineer in the Patents Office. He was 46 years old, and leaves a widow and child.

Atmospheric Electricity.—It is usually thought that there is a normal diurnal variation of the atmospheric electricity in calm weather and a clear sky. M. André, however, has given publication to observations made with a Mascart registering electrometer, which do not confirm these views. The fact seems to be, according to these observations, that there are three physical causes for the variation: direction and force of the wind, barometrical pressure, and amount of water vapour in the air; and that corrected for these there is no diurnal variation.

Double Cylinders.—A new idea in compound engine practice, almost as radical as that of compounding itself, has been put into practical use by F. W. Johnstone, superintendent of the Mexican Central Railway. In this the high-pressure cylinder, of 14in. diameter, is enclosed within the low-pressure cylinder of 30¾in. diameter, giving effective area equal to a cylinder of 24¼in. diameter. The stroke is 24in., and the two rods of the low-pressure cylinder are coupled with the single high-pressure rod to one cross-head. A test of 12 trips is stated to have shown an economy of 25 per cent. in fuel.

Electric Railway Material.—The progress of electric railways in America is well illustrated by a complete catalogue of material for their construction, issued by the Electric Merchandise Company, of Chicago. Testing sets, meters, resistances, lightning arresters, switches, fuses, headlights, and gongs, down to celluloid checks for passengers, are all illustrated in their latest forms, besides trolleys of ingeni[illegible] make, c[illegible]g posts of wood and lattice—plain a[illegible] -ra[illegible] [illegible]tors, and cables. It would form [illegible] [illegible]t method of carrying out el[illegible]

Penzance [illegible] [illegible]enzan[illegible] Town Counci[illegible] [illegible]

the time had arrived when it was advisable that the lighting of the borough should be in the hands of the local authority. After having thoroughly considered the respective merits of gas and electricity and the probable cost of obtaining the necessary orders, acquiring and erecting plant, they recommended that within the forthcoming session application should be made to the Local Government Board for powers for gas. After a long discussion the report was referred back to the committee for reconsideration.

Tulse Hill.—The residence of Mr. G. Mason, G[illegible]thorne, Tulse Hill, has been very thoroughly fitted with electric light by Messrs. F. and C. Osler. Some time ago a 60-light plant was put down, and this has now been extended. The engine-room, 70 yards from the house, contains a Crossley 9-h.p. nominal gas engine, and the current is generated by an Elwell-Parker dynamo. A battery of 53 E.P.S. cells provides for storage. The switches are Osler's glass covered and Edison-Swan tumbler pattern, and the fittings are of handsome design. Cigar lighters and other little accessories make the installation a very complete one.

Saw Mending by Electricity.—The hardest steel at present successfully worked by the electric welding process is the welding of band saws. Besides the regular work of making the joint in continuous band saws, it has been ingeniously adopted for replacing broken teeth in finished saws. Formerly it was necessary to cut down to a smaller size any saw from which one or two teeth had been broken, thus losing not only the difference in price between the two saws, but also the entire cost of the labour in cutting the original saw. Now when a tooth is broken out, they simply fit in a new tooth, which is electrically welded in place, and a drop of oil applied as the completion effectually restores the temper of the saw to a serviceable point.

Search Lights in War.—While glancing recently at an able paper on the engrossing subject of ships *versus* forts in naval warfare, we were glad, says a technical contemporary, to find that the author was of opinion that a little less expenditure on big guns and a little more on large search lights would be distinctly advantageous; and the reader was asked to imagine the utter bewilderment of the captain of an ironclad endeavouring to force a narrow passage at night time in the glare of half a dozen well handled projectors. An involuntary testimony to the value of the search light as a means of defence was, indeed, given recently by the loss at Cherbourg of a torpedo boat, which was cut in two by a cruiser whose captain was dazzled by the rays of a search light.

Telephoning on Telegraph Wires.—An adaptation of the telephone to existing telegraph lines has just been successfully completed between Grangemouth and Glasgow by Mr. J. Erskine Muirhead, of Glasgow. The telephones used are the French type, with microphones. The line has two intermediate stations, one at Port Dundas and the other at Kirkintilloch, but this in no way impaired the speaking; indeed, it is proposed to add other two intermediate stations, making six telephones served by a single line. Though the telegraph instruments were employed simultaneously, there was no interruption; and it is intended that the telegraph instruments shall be discarded. Another feature of the adaptation is that as the wire runs along the canal, the barger can fix a portable telephone on it at any place and speak to the termini.

Free Lighting.—A plan has been thought of by some ingenious people for granting almost free public lighting, and obtaining a business benefit at the same time. The Ashton Town Council have been applied to by the Acme [illegible]ising Company to place tasteful advertisements on [illegible] the 400 lampposts in that town at a price which

will go to greatly reduce the cost of public lighting. A sample advertisement has been put up, and the proposal, appealing as it does to the constant desire of councillors to reduce taxation, is under consideration as to whether the intrusion of such tactics would lessen the dignity or irritate public feeling, or, on the other hand, prove a useful scheme for reducing the lighting rates. It may be remembered that the public kiosks in Paris have a considerable income from advertisements.

Electric Light at Sea.—A complaint regarding the behaviour of the electric light at sea has been made to the Trinity House by the Shipmasters' Society. The Elder Brethren are informed by Lieut. Froud, secretary to the society, that members in active service passing between the Thames and the sea have often represented to the committee the poorness, sometimes invisibility, of electric lights during certain conditions of hazy atmosphere, while the oil lights of lightships and the gas lights of seaside towns have been comparatively bright and distinct. Fault, on the other hand, is also found with the intense and blinding effects of such lights as those of the South Foreland on vessels near at hand. The glare of the electric beam is said to cause ships to cast intense shadows, and to produce a phantom-like appearance of hulls, masts, and sails.

Patent Office.—It is fairly well known that the revenue of the Patent Office is much greater than its expenses, but the exact figures are surprising. Last year the income was £192,606 and the expenditure £83,240, leaving a profit of £109,606, or 56 per cent. of the receipts. This disclosure will no doubt result in an outcry for the reduction of fees, but it might very well result also in a movement for the better examination and testing of the novelty and validity of inventions. It is notorious that the British Patent Office will practically accept any invention, and a case was recently disclosed in which an application for a patent was granted for making gold out of chopped straw. Leaving aside such eccentricities, inventors usually do not feel safe in England as to the priority of their patents, until the patent in Germany, where the scrutiny is far more strict, is granted.

Great Yarmouth.—An advertisement to probable customers is inserted by the town clerk of Great Yarmouth in the local paper, in which it is stated that the Electric Lighting Committee are considering the question of providing an electrical supply for the borough, and are desirous of ascertaining the requirements of the public. Persons wanting a supply are therefore requested to communicate their requirements to the borough surveyor on a form to be obtained at his office. The advertisement goes on to state that the Town Council, as they are at present advised, consider the cost of electricity—light for light—about equal to that of gas at the rates paid within the borough, but persons proposing to take a supply are cautioned that the public generally expect a much more brilliant light from electricity than other modes of lighting, and that this probably increases the cost about 30 per cent.

Harwich.—At the quarterly meeting of the Harwich Town Council, the Mayor was questioned as to the probable cost of lighting the town by electricity. Mr. Parsons, who avowed himself quite in favour of the lighting by that power, provided that the cost was not too great, thought they ought to know the probable cost, so that at the next meeting, on August 27, they would then be able either to vote in favour of or against it. The Mayor said that in the first place there would be a fee of £50 to go to the House of Commons to get their sanction, and then it would afterwards depend upon what opposition was offered to the use of electricity for lighting purposes. Mr. Rose said that the affair had already been before them and settled, so far as the committee was concerned, though he did not say they were going to accept Messrs. Crompton's tender. The Mayor stated the first expense would be 50 guineas for a fee, which Mr. Parsons said was all he wanted to know.

Electric Cars at Clapham.—The Jarman electric cars would seem to be likely to be adopted practically if we are to believe the statements in the daily press. We may premise, however, that this is not by any means the first trial trip, nor, on the other hand, is there anything to prevent the tramways continuing their use if they prove successful and economical. The following is the note referred to: "South London has an electric railway and, if all goes well, will soon possess electric tramcars. By permission of the London Tramways Company, a trial trip was made between High-street, Clapham, and Tooting of a car belonging to the Electric Tramcar Syndicate, and the experiment proved wholly successful. The journey to and fro—a distance of about six miles—was accomplished in some 50 minutes, but at no time was the road clear of traffic, and at several stages the vehicle had to be stopped. The maximum speed attainable is 16 miles an hour, the normal being from seven to eight. An important feature conducive to safety is that in a moment, by manipulating a switch, the motive power can be reversed. Outwardly these cars resemble those ordinarily drawn by horses. In all probability a start with them will be made at Croydon."

Technical Schools.—The council of the Manchester Technical School appointed a committee to visit various technical schools in England and on the Continent. The report of this committee has been presented to the Manchester Whitworth Institute in the form of a full pamphlet, giving details and, what is extremely useful, plans of the schools and laboratories visited. These comprise five technical institutions in Berlin, two at Chemnitz, three at Stuttgart, six at Zurich, two at Winterthur, and one each at Muhlhausen, Crefeld, and Roubaix. Besides this there are in London the City and Guilds Central Institution, the Finsbury College, King's College, and the Polytechnic, Regent-street; and in the provinces the Bradford Technical College, and the technological department of the Yorkshire College, in Leeds. In their general conclusions the committee say that, measured by our standard, the fees are nominal, and in some cases (as Roubaix) there are not only no fees, but all materials are supplied. The danger to our industries from the greater technical instruction is by no means imaginary; for instance, three million pounds in chemicals are imported from Germany and Switzerland, and there is no sound reason, except want of high technical training, why these should not be made in England. They were especially struck with the splendid Polytechnical School in Zurich, and they submit that Manchester similarly requires a technical school of the highest character. No pretence can be made that these schools can be self-supporting; rather on the other hand, the lower the fees, if properly safeguarded by examinations, the more service they can render to the community.

Fatal Electric Light Accident.—An inquest was held at St. Bartholomew's Hospital on Thursday last week on the case we have already mentioned respecting the death of Kate Wilkins, aged five years, the daughter of a watch case maker, residing at 103, St. John-street-road, Clerkenwell. The deceased was passing the Agricultural Hall, Islington, when an electric lamp, weighing 28lb., fell from the top of the hall and struck her on the head. She was knocked down and rendered insensible, and was conveyed shortly afterwards to the hospital, where she died. Mr. William Cumming, a gasfitter, who saw the lamp fall, was of opinion that the rope wire produced (which was 38 strand) was not sufficient to bear the weight, owing

to the length the lamp was suspended. He would not be surprised to hear that the wire rope had been tested to carry a ton weight, but it all depended what length of wire the weight was hanging upon. William Trickett, electrical engineer, stated that he was responsible for the fixing of the lamp, and on the day in question it was pulled tight to the window-sill. It had previously been suspended from the top of the building. The witness was of opinion that there had been a leak in one of the wires, and that the current had gone to earth and passed to the stone coping. The result was that the wire was burned clean through by the current, and the lamp fell. The reason that the lamp was suspended from the window-sill was because the wire rope had run off the pulley at the top that day, and there had been no time to refix it. After the lamp fell the wire was found to be hot, and on opening the strands a piece of string which ran down the middle of the wire was burned. The switch by which the current was connected was in a brick wall, and witness was of opinion that the current escaped at that point. The wet weather would greatly help the current to pass by way of the coping. The switch was 200ft. away from the point where the wire burned through, and he had never before heard of a similar occurrence. It was a thing almost impossible to provide against, as it was so improbable that it would happen. A verdict of "Accidental death" was returned.

Taunton Exhibition.—The catalogue of the Taunton Electrical Exhibition is a handsome affair, containing many local advertisements and much useful information, with illustrations upon electrical topics. The exhibition is primarily constituted for the better spreading of a taste for and knowledge of electric light and power, and naturally bears largely on the work of the Taunton Electric Company, so successfully worked by Mr. Massingham. This installation is fully described in the catalogue, and its development and benefits set forth. The following are the exhibitors: The Italian Art Fittings Company, Exeter, have hammered brass and copper fittings; Rashleigh, Phipps, and Dawson have art metal fittings and their ray diffuser; the Steam Loop Company show a working model steam loop; Automatic Screw Company, electrical screws; E. Goodman and Son are the printers of the catalogue; Dart Bros., spectacles for examining arc lights; American Camera Company show students' apparatus; King, Mendham, and Co., influence machines and apparatus; John Taylor and Sons, Nottingham, the "Midland" gas engine; Furnival and Co., Reddish, the "Express" gas engine; Davis and Sons, Bath, switches, motors, and apparatus; T. Jenner, Taunton, has many novel inventions—protective switches, self-tightening grip-tools, patent holders, etc.; the Blackman Ventilating Company; Andrew and Co., 6-h.p. Stockport gas engine; Jos. J. Armfield and Co., Ringwood, turbines and turbine gear; Richard Frères, registering meters; F. M. Newton, "Taunton" dynamo and motors driving various machines; G. Gilkes and Co., Kendal, 25-h.p. turbine. The City of Bath Electric Lighting Company have, of course, one of the largest exhibits, containing all manner of electric lighting apparatus, and the Exeter Electric Light Company have a show of electroliers. The Keys' Electric Company exhibit motors doing churning, knife-cleaning, and so forth; James Beach, Taunton, electroplating; Easton and Waldegrave, 3-h.p. engine and boiler for electric lighting; Appleton, Burbey, and Williamson show contractors' supplies—one to 4,000 amperes; Babcock and Wilcox Company have a model of their boiler; and Laurence, Scott, and Co. show their "N——ch" motors, dynamos, and switches.

Electric Lighting in London.—Nothing will aw... the minds of the public in general to the immense sp... of electric lighting in London more than an exha... article in the *Times*, except, perhaps, the sudden appeara... of arc lights down the Strand. The latter phenomena w... have not as yet. Trafalgar-square must await its enlighten... ment. But the *Times* this week (Aug. 19) has vigorous... taken the matter up, and in an ably written article o... the "Growth of Electric Lighting in London," and a... leader upon the subject, has drawn the world's attention t... what has been gradually though rapidly happening in th... metropolis. Three years ago, in 1888, only one elec... supply company, the Grosvenor, was worth calling b... name. In these three years, in London alone, electric... supply companies have been formed with an aggrega... capital of £3,000,000. Instead of one station we have ... and the 6,000 lamps then lighted from Bond-street ha... grown to 240,000, with over 240 miles of undergrou... copper mains. Adding the private installations, ... careful enquiries made by Mr. Frank Bailey, engin... to the Metropolitan Company, went to show that a total ... 325,000 lamps of 8 c.p. might be taken as the total ... total, besides 1,000 arc lamps. It is evident that th... electric light has "come to stay." The article goes ... thoroughly into the different systems of the various stati... from the 10,000 volts of Deptford to the 100 volts ... Whitehall. The Chelsea Company of all the suppliers h... combined high pressure with continuous current. "Up... the face of it," says the writer, "such a system, combini... economy in mains with the principle of 'storage' and t... other advantages of direct current, would seem to h... hit the right nail on the head, and to be destined to a gr... future. Strangely, enough, however, there is not a syst... of distribution in London that has fewer friends amon... electrical engineers"—due, we may imagine, to the co... paratively extreme complexity of the regulating applia... hitherto judged necessary. The article comments up... municipal undertakings, pointing out that local authori... can borrow money at 3 or 3½ per cent., whereas elect... shareholders expect, and may receive, up to 10 per ce... The paper concludes with a comparative table of t... various electric light companies of London, with particul... of capital, horse-power, lamps, mains, and districts.

Keys' Company's Catalogue.—We are in rece... of the catalogue just issued by the Keys' Electric Compa... Charing Cross road. This is very full and very vari... but is in the rather cumbrous form of a score or ... of separate pamphlets, covered back and front w... advertisements; and not being numbered or inde... at all, and of the same appearance, they are a li... awkward to refer to. They have their convenie... however, as each department is to itself. Accu... lator plant shows regulating switches, automatic cut-o... and testing bell; insulators and insulator bobbins, elec... casings, flexible cords are illustrated by a pamphlet a pi... while the item switches have a whole flock—the "Pais... switch, the "Royal" switches—a neat and business-li... quick-break—ship switches, china-base, "see-saw" switch... decorated house switches, two-way switches, flexib... switches, main knife-edge switches, besides which are so... really magnificent specimens of station switchboar... One of these—"Switchboard No. 71"—has the appearan... of a veritable signalman's box. It was made for t... Madrid central station for two dynamos of 1,800 amper... and four of 1,200 amperes, for the three-wire system, for t... supply of current to 22,000 16-c.p. lamps at one time. T... whole board cost about £1,500. Switchboard No. 72 ... for a low-tension system with accumulators, and was ma... for the Asia Quay, Hamburg. Switchboard No. 73 is

handsomely moulded arrangement for ordinary house installations for dynamos and accumulators, in carved work, with switches, instruments, and cut-outs, both solidly and tastefully arranged. Lampholders are of course illustrated. The Keys' Company have a speciality in incandescent lamps which they term the "Star," of which 5,000 a day are made. They are made for export only in England in 4, 6, 8, 10, 16, 20, 25, 32, 50, and 100 candle-power. The "Luna" arc lamp seems simple and easily adjusted; several arrangements of suspension gear are shown. Amongst the more particular specialties are the "Berlin" dynamos, electric motors applied to a greater variety of purposes, a very complete set of electric lighting arrangements for theatres—including stage regulators, group regulators, temporary connections, supplementary lights, three-light stage effects, hanging lamps, etc. The catalogue of the very ingenious and manifold physical apparatus designed by Dr. Edelmann for research and laboratory purposes is a perfect mine of description of valuable and interesting instruments.

Egremont.—Messrs. Nicholson and Jennings, electric engineers, Newcastle-on-Tyne, have been in communication with the Egremont Local Board as to electric lighting by water power, for which 40 brake horse-power would be required. At the last meeting of the Board the clerk said Mr. Boyd, the surveyor, supplied the following particulars, which were forwarded to Messrs. Nicholson and Jennings: "I have, as requested, seen Mr. Head, the millwright, with reference to the power that can be got from the River Ehen at Egremont, and his opinion is that the paper mill in the parish of St. John's, belonging to Mr. Thos. Grice, of Bootle, and at present occupied by Joe. Ramsay, is the best and most suitable place. There is a good waterwheel ready, only requiring a little repair, and he calculates that in summer, at least 30 h.p. is available and in winter 60 h.p. On the 11th inst. I gauged the quantity of water going over the weir at this mill at 11 a.m., and found it to be about 3,000 cubic feet per minute, and there is 10ft. of fall at the wheel, which gives 34 h.p. On the same day at 12 noon I gauged the water passing at the Bleach Green weir and race, and found it to be 2,500 cubic feet per minute. This, with 10ft. head, would give 28 h.p. The water in the river had fallen considerably between 11 and 12 o'clock, which would no doubt account for the difference in the two gaugings. The Bark Mill would be of no use for the purpose intended, as it can only have the water when not required by the corn mill, and the present wheel is only 6 h.p. or 8 h.p. At Little Mill, by putting up a turbine, 25 h.p. in summer and 30 h.p. in winter might be got. From the above information, I think the paper mill is the most likely place, and could be fitted up at least cost." Messrs. Nicholson and Jennings, in reply to this, said the power was too near that required, 40 h.p., but the number of lamps might be reduced, each lamp taking 1 h.p. They added: "As long as you are sure of getting 40 actual horse-power, you would be quite safe. We would suggest your sending the particulars to Gilbert Gilkes and Co., late Williamson Bros., Canal Iron Works, Kendal. They have had very considerable experience in this class of work, and have put up some very efficient low-fall turbines, and will be only too glad to give you an opinion, and if necessary the price of a turbine." The following, from a letter from the Keswick Electric Lighting Company, was also read: "The electric light is used in private houses, shops, and hotels, and is found quite satisfactory. The power is acquired by a Victor turbine, with 20ft. head of water giving 50 h.p., and steam power 50 h.p. in case of water running low either in dry or frosty weather. In front of the Keswick Hotel there is an arc lamp of 1,000 c.p., which is calculated to take 1 h.p. to supply. The front space has occasionally been used for a night drill of the volunteers." A committee was appointed to consider this correspondence, with power to call in professional assistance if necessary.

Liege University.—It is a curious fact, says the Paris correspondent of the *Standard*, that one of the first schools for teaching the science and applications of electricity to industry was opened at the University of Liège, the town to which the poor joiner's lad Gramme, born in 1826, at Jehay Bodegnée, Belgium, came to work, and at the same time to study geometry and mathematics at the free classes for adults. Had it not been for the knowledge he thus acquired at Liège, he would never have been able to understand the theories of the Italian *savant* Paccinotti, and to apply them in an invention which has made his name celebrated in every civilised country. One of the first schools of electricity was opened in 1883 at the same university. The initiative in this creation was taken by M. Montefiore-Levi, the Belgian senator and philanthropist, who is almost as well known throughout Europe and America as in his own country. In endowing the University of Liège with an electro-technical section, M. Montefiore-Levi had the double object in view of opening up a new and lucrative career to the students of the university where he himself had been educated, and of encouraging the electrical industries by facilitating the recruiting of their *personnel*, who require to have a thorough technical knowledge of electricity. He commenced by placing a sum of 100,000f. at the disposal of the Government for the preliminary cost of the purchase of the necessary instruments and materials, but since then he has gone on giving annually larger amounts, in proportion as the needs of the new school grew with its rapid development. The Government, on its side, furnished the buildings, but as the University of Liège was being rebuilt the electrical section was at first housed in modern constructions in the courtyard of the main buildings. This year it has been allotted a thoroughly appropriate building, containing workshops and laboratories. It is, indeed, so spacious that it has been possible to provide a separate laboratory for every two students of electricity. On this occasion M. Montefiore-Levi has given 150,000f. to provide the workshops and laboratories with all the necessary instruments and materials to enable students to make, not only the experiments requisite for their studies, but also experiments for new discoveries and inventions. The practical utility of the institution has been already amply demonstrated. All the students who have in any way distinguished themselves at it are sought after by the chiefs of the electrical industry. It would also be easy to give a long list of the useful inventions made by former pupils; but as imitation constitutes the most valuable praise, it will suffice to note that the Italian Government has followed the example set at Liège by creating a similar electrical school at the University of Milan, and by placing Signor Zurini, one of the former students of the Liège school, at its head. But though the electrical section of the Liège University owes its existence to M. Montefiore-Levi, its success and rapid development have been due to the untiring exertions of Prof. Eric Gérard, who has presided over it ever since it was created. M. Eric Gérard is a distinguished electrician, well known throughout Europe as having been the delegate of the Belgian Government at almost all the electrical congresses that have been held for many years past. He is a comparatively young man, having been born at Liège in 1856. When 22 years of age, he left the University of Liège and completed his electrical studies at the Belgian Ecole Supérieure de Télégraphie. M. Gérard has also written largely on electrical science.

ON A TEST OF EWING AND MACGREGOR'S METHOD OF MEASURING THE ELECTRICAL RESISTANCE OF ELECTROLYTES.*

BY PROF. J. G. MACGREGOR, D.SC., DALHOUSIE COLLEGE, HALIFAX, N.S.

(Concluded from page 152.)

To test the method described, I have compared the results it gives for the resistance of a tube containing zinc sulphate solution, with the results obtained by connecting up the tube as one of the arms of the bridge by means of amalgamated zinc electrodes and using the ordinary bridge method. As in this particular case there is no polarisation, and the measurement may be made as exactly as in the case of a metallic conductor, such a comparison forms a rigorous test of the reliability of the method under consideration.

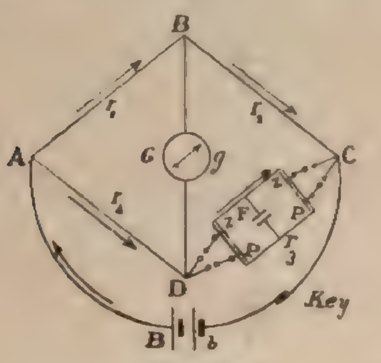

FIG. 1.

The electrolytic cell (F, in Fig. 1) which I used, consisted of a box formed of strips of window glass cemented together with marine glue. Its length was about 16 cm., breadth about 10 cm., and depth about 5 cm. It was divided traversely into two compartments of equal length by a glass partition cemented so as to be water-tight. Through the centre of this partition passed a tube whose length was different in different experiments. It was cemented at right angles to the partition, and its ends were open. At each end of the box were two electrodes, one of platinum (P) and one of zinc (Z), side by side, but not in contact. They were square with narrow strips projecting above the upper edge of the ends of the box. They were of approximately equal area, having edges about 4·5 cm. in length. Wires passed from the upper ends of the strips to brass binding screws fixed in and supported by blocks of solid paraffin. The wires from the zinc electrodes were of copper and had been soldered to the zinc without the use of acid. Those from the platinum electrodes were of platinum and had been welded to the electrodes. In both cases the wires were so thick that their resistance relatively to that of the electrolytic cell was small and might be neglected. From the binding screws thick copper wires passed to mercury pools in blocks of solid paraffin. From contiguous pools other wires passed to the ends C and D of the arms B C and A D of the bridge; and by connecting the proper pools by means of wires, the electrolytic cell might be joined up as an arm of the bridge either by means of the platinum or of the zinc electrodes.

The electrodes were in all cases placed as close as possible to the ends of the box. I did not attempt to place them at exactly the same distance, but satisfied myself by preliminary experiments that slight differences in the placing of the electrodes made no appreciable difference in the resistance of the cell.

With this cell (1) it was the same mass of liquid whose resistance was measured, whether the platinum or the zinc electrodes were used to connect it with the other arms of the bridge, and (2) t[illegible] a large mass of liquid in the cell. [illegible]ing i[illegible] of this mass of liquid, the tim[illegible] ion of a measurement of [illegible] ctrodes [illegible] ned an[illegible] e with elec[illegible] an[illegible]

being approximately at the temperature of the [illegible] the temperature of the tube must have been [illegible] same at the times of both measurements.

The only available box of resistance coils was a [illegible] made by Stoehrer, of Leipzig. The coils were arra[illegible] as to form three arms of a Wheatstone's bridge. T[illegible] them contained two coils each of 100 and 10 Siemens [illegible] respectively. The third contained a number of coils [illegible] from 500 to 1 Siemens units.

I had no galvanometer well adapted to the expe[illegible] I therefore extemporised one by combining the core [illegible] Thomson's dead beat galvanometers (made by Elliot[illegible] a pair of coils from a Wiedemann's galvanometer ([illegible] Stoehrer). Both these coils were differentially [illegible] and thus I could vary the resistance of the galva[illegible] by combining them in different ways. Neverthele[illegible] not in any case able to give the galvanometer the re[illegible] which it ought to have had to attain the maximum se[illegible] ness in the bridge. The lightest mirror which was a[illegible] weighed, with the magnet attached, about 0·06 g[illegible] just about twice as much as that used by Mr. Ew[illegible] myself in our experiments. The diameter of the [illegible] was about 9 mm. My extemporised galvanome[illegible] another defect—viz., that the inner windings of t[illegible] were about 4 cm. from the magnet.

In making observations by the two methods, I in[illegible] first used the method under test, the cell being co[illegible] with the other arms of the bridge by means [illegible] platinum electrodes, and immediately afterwards [illegible] mined the resistance with the cell connected up by [illegible] the zinc electrodes. In this way I avoided bias.

I varied the resistance of the cell by chang[illegible] strength of the solution, or by introducing short g[illegible] into the tube, or by using tubes of different length[illegible] resistance of the cell was in these ways made to va[illegible] about 100 to about 4,000 Siemens units.

It would be useless to give the values of the re[illegible] which the cell was found to have in the different [illegible] tions made, as these values have no permanent imp[illegible] The general results were as follows:

1. As was to be expected, the resistance was [illegible] invariably found to be greater when determined [illegible] method under test than when determined by th[illegible] method.

2. When the resistance of the electrolytic cell wa[illegible] say from 3,000 to 4,000 units, its value as determ[illegible] our method differed from its true value, as given [illegible] use of the amalgamated zinc electrodes, by from 0·[illegible] per cent. There was rarely so great a difference a[illegible] cent., and in many cases the differences were less [illegible] per cent. When, however, the resistance of the [illegible] small, say from 100 to 200 units, the differenc[illegible] much larger, amounting even in some cases to 6 an[illegible] cent. This unsatisfactory result, however, was cle[illegible] to the fact that my box of resistance coils was so sm[illegible] when the electrolytic cell had a small resistance I c[illegible] sufficiently reduce the current flowing through it [illegible] so increasing the resistance of the battery as to [illegible] seriously the sensitiveness of the bridge. The [illegible] of the method under consideration, therefore, i[illegible] by the observations above referred to, with [illegible] so constructed as to have a high resistance [illegible] agreement of these observationss seems to m[illegible] very satisfactory, especially when we conside[illegible] as pointed out above, the galvanometer with wh[illegible] observations were made was so seriously defective. [illegible] a galvanometer of proper construction,* the error [illegible] undoubtedly be reduced to a still smaller magnitu[illegible] requires to be reduced only to 0·054 per cent. to be [illegible] small as the difference found by Kohlrausch and Gr[illegible] between the resistance of a tube of zinc sulphate [illegible] as determined by their admittedly satisfactory meth[illegible] as determined by the use of amalgamated zinc electr[illegible]

I think, therefore, we may conclude that the [illegible] nometer has already been constructed by the aid of [illegible] the method under consideration may be applied [illegible]

* [illegible]

* Magnet-mirrors are now made I believe with mo[illegible] [illegible]ertia of only 6·10 $^{-8}$ C.G.S. units. The one I used had a [illegible] [illegible]ertia of 2400·10 $^{-8}$ C.G.S. units.

agencies within the soil, at the same time favouring the easy sliding of the cables during the drawing-in operations.

Fig. 8 shows a section of the profile of the shaped wood; Fig. 9 represents a model of the kind of support used in tunnels and manholes.

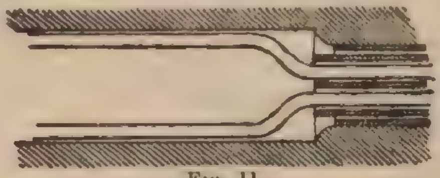

Fig. 11.

When crossing the streets the trenches, terminated at the manholes, are covered in, connected under the roadway by a horizontal gallery, and at the level of the pavement by iron covers. The depth of these pits varies from two to 10 yards, determined by the existence and relative position of drains and water or gas pipes beneath the street.

Fig. 12.

Fig. 13.

Issuing from the cast-iron conduits, the cables are taken down into the pits—positives to one side and negatives to the other—carried at a distance from the sides by clamps of paraffined wood, similar to those in Fig. 9, attached to

Fig. 14.

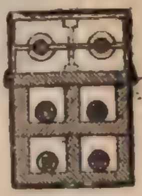

Fig. 17.

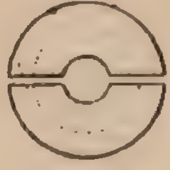

Fig. 15.

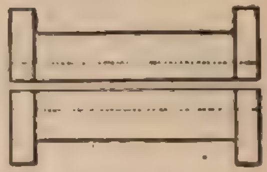

Fig. 16.

arms fastened on the brickwork. After entering the gallery they are arranged in the same manner upon the inside surface of the vault (Figs. 10 to 12). The cables are firmly fastened by screws in the clamps, the clamps being constructed to carry from three to 16 cables.

The method of laying bare cables differs from that just explained. These are always placed within cast-iron

* From *L'Electricien.*

conduits. Sometimes they are laid together with feeders in the same passage way. The bottom of the conduit is furnished with a paraffined deal plank, upon which are bolted at intervals of 3ft. to 6ft. oak carriers in two pieces, whose length is equal to the transverse section of the conduit (Figs. 13 and 14). Porcelain insulators (Figs. 15 and 16) are fixed in these oak pieces, and through these are drawn the bare cables. In the cases where high-tension

pits of small dimensions, communicating with the con and covered in with a cast-iron lid, generally filled in with asphalte. The cables follow the contour of the carried by paraffined wood supports. The diagram with sufficiently explain the arrangement.

In the installation of any system of underground be it for water, gas, compressed fluids, or of elec certain circumstances supervene, often inconv

RIMENTS WITH ALTERNATE CURRENTS OF 'Y HIGH FREQUENCY AND THEIR APPLICA- N TO METHODS OF ARTIFICIAL ILLUMINA- N.*

BY NIKOLA TESLA.

(Concluded from page 161).

ideal way of lighting a hall or room, would, how- e to produce such a condition in it that an illumi- device could be moved and put anywhere, and t is lighted, no matter where it is put, and t being electrically connected to anything. I een able to produce such a condition by creating room a powerful, rapidly alternating electrostatic For this purpose I suspend a sheet of metal a e from the ceiling on insulating cords and connect it terminal of the induction coil, the other terminal referably connected to the ground. Or else I sus- wo sheets as illustrated in Fig. 30, each sheet being ted with one of the terminals of the coil, and their ing carefully determined. An exhausted tube may carried in the band anywhere between the sheets ed anywhere, even a certain distance beyond them; ins always luminous.

ich an electrostatic field interesting phenomena may rved, especially if the alternations are kept low and entials excessively high. In addition to the luminous phenomena mentioned, one may observe that any insulated conductor gives sparks when the hand or another object is approached to it, and the sparks may often be powerful. When a large conducting object is fastened on an insulating support, and the hand approached to it, a vibration, due to the rythmical motion of the air molecules, is felt, and luminous streams may be perceived when the hand is held near a pointed projection. When a telephone receiver is made to touch with one or both of its terminals an insulated conductor of some size, the telephone emits a loud sound; it also emits a sound when a length of wire is attached to one or both terminals, and with very powerful fields a sound may be perceived even without any wire.

How far this principle is capable of practical application the future will tell. It might be thought that electrostatic effects are unsuited for such action at a distance. Electromagnetic inductive effects, if available for the production of light, might be thought better suited. It is true the electrostatic effects diminish nearly with the cube of the distance from the coil, whereas the electromagnetic inductive effects diminish simply with the distance. But when we establish an electrostatic field of force, the condition is very different, for then, instead of the differential effect of both the terminals, we get their cojoint effect. Besides, I would call attention to the fact, that in an alternating electrostatic field, a conductor, such as an exhausted tube for instance, tends to take up most of the energy, whereas, in an an electromagnetic alternating field the conductor tends to take up the least energy, the waves being reflected with but little loss. This is one reason why it is difficult to excite an exhausted tube, at a distance, by electromagnetic induction. I have wound coils of very large diameter and of many turns of wire, and connected a Geissler tube to the ends of the coil with the object of exciting the tube at a distance; but even with the powerful inductive effects producible by Leyden jar discharges, the tube could not be excited unless at a very small distance, although some judgment was used as to the dimensions of the coil. I have also found that even the most powerful Leyden jar discharges are capable of exciting only feeble luminous effects in a closed exhausted tube, and even these effects upon thorough examination I have been forced to consider of an electrostatic nature.

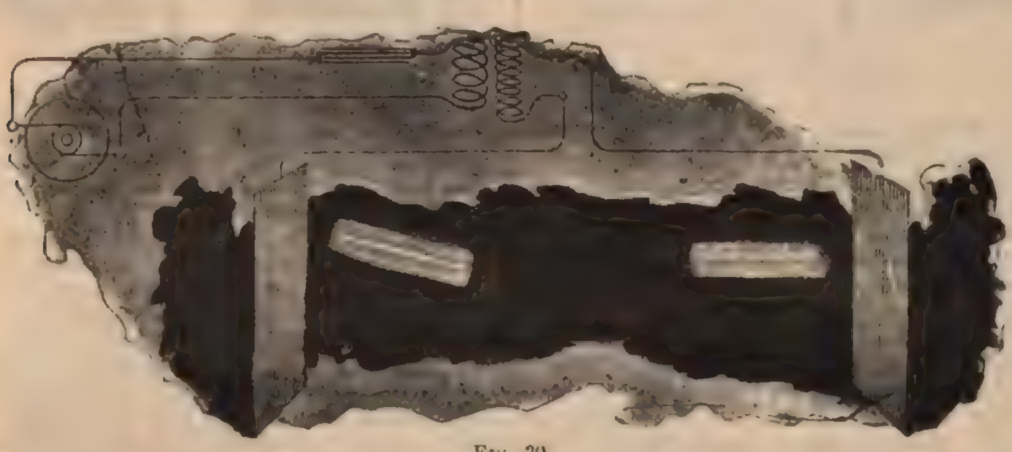

FIG. 30.

How, then, can we hope to produce the required effects at a distance by means of electromagnetic action, when even in the closest proximity to the source of disturbance, under the most advantageous conditions, we can excite but faint luminosity? It is true that when acting at a distance we have the resonance to help us out. We can connect an exhausted tube, or whatever the illuminating device may be, with an insulated system of the proper capacity, and so it may be possible to increase the effect qualitatively, and only qualitatively, for we would not get more energy through the device. So we may by resonance effect obtain the required E.M.F. in an exhausted tube, and excite faint luminous effects, but we cannot get enough energy to render the light practically available, and a simple calculation, based on experimental results, shows that even if all the energy which a tube would receive at a certain distance from the source should be wholly converted into light, it would hardly satisfy the practical requirements. Hence the

ture delivered before the American Institute of Electrical rs at Columbia College, New York, May 20.

necessity of directing, by means of a conducting circuit, the energy to the place of transformation. But in so doing we cannot very sensibly depart from present methods, and all we could do would be to improve the apparatus.

From these considerations it would seem that if this ideal way of lighting is to be rendered practicable it will be only by the use of electrostatic effects. In such a case the most powerful electrostatic inductive effects are needed; the apparatus employed must, therefore, be capable of producing high electrostatic potentials changing in value with extreme rapidity. High frequencies are especially wanted, for practical considerations make it desirable to keep down the potential. By the employment of machines, or, generally speaking, of any mechanical apparatus, but low frequencies can be reached; recourse must, therefore, be had to some other means. The discharge of a condenser affords us a means of obtaining frequencies by far higher than are obtainable mechanically, and I have accordingly employed condensers in the experiments to the above end.

When the terminals of a high tension induction coil, Fig. 31, are connected to a Leyden jar, and the latter is discharging disruptively into a circuit, we may look upon the arc playing between the knobs as being a source of alternating, or generally speaking, undulating currents, and then we have to deal with the familiar system of a generator of such currents, a circuit connected to it, and a condenser bridging the circuit. The condenser in such case is a veritable transformer, and since the frequency is excessive, almost any ratio in the strength of the currents in both the branches may be obtained. In reality, the analogy is not quite complete, for in the disruptive discharge we have most generally a fundamental instantaneous variation of comparatively low frequency, and a superimposed harmonic vibration, and the laws governing the flow of currents are not the same for both.

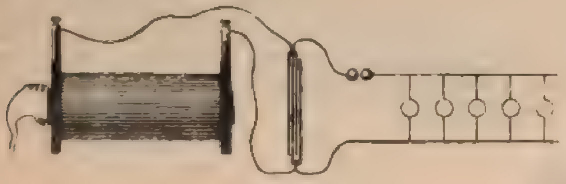

Fig. 31.

In converting in this manner, the ratio of conversion should not be too great, for the loss in the arc between the knobs increases with the square of the current, and if the jar be discharged through very thick and short conductors, with the view of obtaining a very rapid oscillation, a very considerable portion of the energy stored is lost. On the other hand, too small ratios are not practicable for many obvious reasons.

As the converted currents flow in a practically closed circuit, the electrostatic effects are necessarily small, and I therefore convert them into currents or effects of the required character. I have effected such conversions in several ways. The preferred plan of connections is illustrated in Fig. 32. The manner of operating renders it easy to obtain by means of a small and inexpensive apparatus enormous differences of potential which have been usually obtained by means of large and expensive coils. For this it is only necessary to take an ordinary small coil, adjust to it a condenser and discharging circuit, forming the primary of an auxiliary small coil, and convert upward. As the inductive effect of the primary currents is excessively great, the second coil need [illegible] comparative[illegible] few turns. By properly adju[illegible] [illegible]ements re[illegible] [illegible]ults may be secured.

In endeavouri[illegible] the re[illegible] [illegible]atic effects in this m[illegible] as m[illegible] [illegible]d, encountered many [illegible] I hav[illegible] overcoming, but I [illegible] pared my experience [illegible]

I believe t[illegible] [illegible]f a play an imp[illegible] bilities, not [illegible]

efficient manner and in the line indicated by theory, but also in many other respects.

For years the efforts of inventors have been dir[ected] towards obtaining electrical energy from heat by means of the thermopile. It might seem invidious to remark but few know what is the real trouble with the thermo[pile]. It is not the inefficiency or small output—though these are great drawbacks—but the fact that the thermopile has its phylloxera—that is, that by constant use it is deteriorated, which has thus far prevented its introduction on an industrial scale. Now that all modern research seems to point with certainty to the use of electricity of excessively high tension, the question must present itself to many whether it is not possible to obtain in a practicable manner this form of energy from heat. We have been used to look upon an electrostatic machine as a plaything, and somehow we couple with it the idea of the inefficient and impractical. But now we must think differently, for now we know that everywhere we have to deal with the same forces, and that it is a mere question of inventing proper methods or apparatus for rendering them available.

In the present systems of electrical distribution, the employment of the iron with its wonderful magnetic properties allows us to reduce considerably the size of the apparatus; but, in spite of this, it is still very cumbersome. The more we progress in the study of electric and magnetic phenomena, the more we become convinced that the present methods will be short-lived. For the production of light, at least, such heavy machinery would seem to be unnecessary. The energy required is very small, and if light can be obtained as efficiently as, theoretically, it appears possible, the apparatus need have but a very small output. There being a strong probability that the illuminating methods of the future will involve the use of very high potentials, it seems very desirable to perfect a contrivance capable of converting the energy of heat into energy of the requisite form. Nothing to speak of has been done towards this

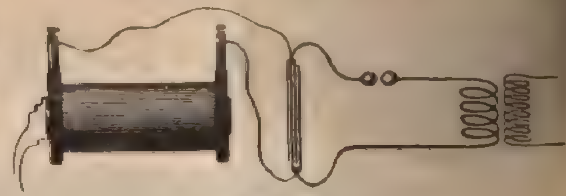

Fig. 32.

end, for the thought that electricity of some 50,000 or 100,000 volts pressure or more, even if obtained, would be unavailable for practical purposes, has deterred inventors from working in this direction.

In Fig. 31 a plan of connections is shown for converting currents of high, into currents of low, tension by means of the disruptive discharge of a condenser. This plan has been used by me frequently for operating a few incandescent lamps required in the laboratory. Some difficulties have been encountered in the arc of the discharge which I have been able to overcome to a great extent; besides this and the adjustment necessary for the proper working, other difficulties have been met with, and it was easy to operate ordinary lamps, and even motors, in this manner. The line being connected to the ground, all the wires could be handled with perfect impunity, no matter how high the potential at the terminals of the condenser. In these experiments a high-tension induction coil, operated from a battery or from an alternate-current machine, was employed to charge the condenser; but the induction coil might be replaced by an apparatus of a different kind, capable of giving electricity of such high tension. In this manner, direct or alternating currents may be converted, and in b[illegible] cases the current-impulses may be of any desired [illegible]ency When the currents charging the condenser a[illegible] [illegible]he same direction, and it is desired that the converte[illegible] [illegible] should also be of one direction, the resistanc[illegible] [illegible]harging circuit should, of course, be so chosen t[illegible] no oscillations.

In ope[illegible] [illegible] on the above plan, I have observed [illegible]us p[illegible] impedance which are of interest. [illegible] stan[illegible] copper bar be bent, as indicated in

Fig. 33, and shunted by ordinary incandescent lamps, then, by passing the discharge between the knobs, the lamps may be brought to incandescence although they are short-circuited. When a large induction coil is employed it is easy to obtain nodes on the bar, which are rendered evident by the different degree of brilliancy of the lamps, as shown roughly in Fig. 33. The nodes are never clearly defined, but there are simply maxima and minima of potentials along the bar. This is probably due to the irregularity of the arc between the knobs. In general when the above described plan of conversion from high to low tension is used, the behaviour of the disruptive discharge may be closely studied. The nodes may also be investigated by means of an ordinary Cardew voltmeter which should be well insulated. Geissler tubes may also be lighted across the points of the bent bar; in this case, of course, it is better to employ smaller capacities. I have found it practicable to light up in this manner a lamp, and even a Geissler tube, shunted by a short heavy block of metal, and this result seems at first very curious. In fact, the thicker the copper bar in Fig. 33, the better it is for the success of the experiments, as they appear more striking. When lamps with long slender filaments are used it will be often noted that the filaments are from time to time violently vibrated, the vibration being smallest at the nodal points. This vibration seems to be due to an electrostatic action between the filament and the glass of the bulb.

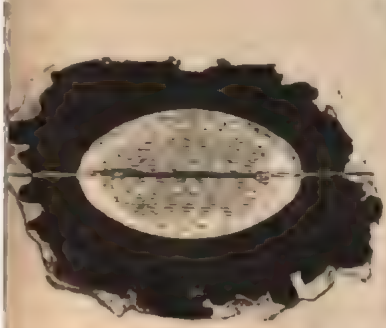

FIG. 34.

FIG. 33.

In some of the above experiments it is preferable to use special lamps having a straight filament, as shown in Fig 34. When such a lamp is used a still more curious phenomenon than those described may be observed. The lamp may be placed across the copper bar and lighted, and by using somewhat larger capacities, or, in other words, smaller frequencies, or smaller impulsive impedancies, the filament may be brought to any desired degree of incandescence. But when the impedance is increased a point is reached when comparatively little current passes through the carbon, and most of it through the rarified gas; or perhaps it may be more correct to state that the current divides nearly evenly through both, in spite of the enormous difference in the resistance, and this would be true unless the gas and the filament behave differently. It is then noted that the whole bulb is brilliantly illuminated, and the ends of the leading-in wires become incandescent and often throw off sparks in consequence of the violent bombardment, but the carbon filament remains dark. This is illustrated in Fig. 34. Instead of the filament a single wire extending through the the whole bulb may be used, and in this case the phenomenon would seem to be still more interesting.

From the above experiment it will be evident that when ordinary lamps are operated by the converted currents, those should be preferably taken in which the platinum wires are far apart, and the frequencies used should not be too great, else the discharge will occur at the ends of the filament or in the base of the lamp between the leading-in wires, and the lamp might then be damaged.

In presenting to you these results of my investigation on the subject under consideration, I have paid only a passing notice to facts upon which I could have dwelt at length, and among many observations I have selected only those which I thought most likely to interest you. The field is wide and completely unexplored, and at every step a new truth is gleaned, a novel fact observed.

How far the results here borne out are capable of practical applications will be decided in the future. As regards the production of light, some results already reached are encouraging, and make me confident in asserting that the practical solution of the problem lies in the direction I have endeavoured to indicate. Still, whatever may be the immediate outcome of these experiments, I am hopeful that they will only prove a step to further development towards the ideal and final perfection. The possibilities which are opened by modern research are so vast that even the most reserved must feel sanguine of the future. Eminent scientists consider the problem of utilising one kind of radiation without the others a rational one. In an apparatus designed for the production of light by conversion from any form of energy into that of light, such a result can never be reached, for no matter what the process of producing the required vibrations, be it electrical, chemical, or any other, it will not be possible to obtain the higher light vibrations without going through the lower heat vibrations. It is the problem of imparting to a body a certain velocity without passing through all lower velocities. But there is a possibility of obtaining energy not only in the form of light, but motive power, and energy of any other form, in some more direct way from the medium. The time will be when this will be accomplished, and the time has come when one may utter such words before an enlightened audience without being considered a visionary. We are whirling through endless space with an inconceivable speed, all around us everything is spinning, everything is moving, everywhere is energy. There must be some way of availing ourselves of this energy more directly. Then, with the light obtained from the medium, with the power derived from it, with every form of energy obtained without effort, from the store forever inexhaustible, humanity will advance with giant strides. The mere contemplation of these magnificent possibilities expands our minds, strengthens our hopes, and fills our hearts with supreme delight.

GODMANCHESTER.

The following comparative statement of the advantages and relative cost of electric light and gas from Messrs. Ernest Scott and Co., Newcastle-on-Tyne, was read by the clerk at the last meeting of the Godmanchester Town Council:

Electric light.—250 lamps of 16 c.p., 1,000 hours.

	£	s.	d.
Coal for 25 h.p., 1,000 hours, at 2½lb. per i.h.p. per hour, 28 tons at 8s.	11	4	0
Oil per week at 2s. 6d.	6	10	0
Sundries at 2s. 6d.	6	10	0
Lamp renewals, 250 lamps at 3s. 9d.	46	17	6
	71	1	6
Add 10 per cent. interest and depreciation on plant, say £400	40	0	0
	£111	1	6

Gas.—250 burners, 6ft. per hour, 1,000 hours.

	£	s.	d.
Cost of gas consumed, 1,500,000ft. at 2s. 6d. per 1,000ft.	187	10	0
Cost of replacing burners and repairs, 5s. per week	13	0	0
	200	10	0
Add 5 per cent. interest on capital expended on fittings, on say £150	7	10	0
	£208	0	0

BOUND VOLUMES.

Vols. I. to VII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

BRITISH ASSOCIATION—THE PRESIDEN ADDRESS.

As was to be expected, and as desirable, presidential address to the Cardiff meeting of British Association discourses mainly on nomical questions. It is extremely intere however, to notice how interdependent are various branches of science. Advance in direction leads to advance in other direction new departure in photography means an exte of the range of astronomical research, for, Huggins says, "The more recent discovery of gelatine plate has given a further great impet this modern side of astronomy, and has open pathway into the unknown of which even enthusiast 30 years ago would scarcely have dar dream." That electrical research will play its in astronomical matters is shadowed by such graphs in the address as that relating to the tention of Stas, who maintains "that electric sp are to be regarded as distinct from flame spec although other observers do not agree with But, as Dr. Huggins says, "The presence of in the solar spectrum which we can only pro electrically is an indication of the high temper of the sun." Advance in spectroscopy seems determined by advance into the regions of mole physics. Hitherto many suggestions have made, but real progress has in this domain comparatively slow. In the early part of his add the president points out a real evil—in too h forming a conclusion—and states "the pro of science has been greatly retarded by re important conclusions upon the apparent coinci of single lines in spectroscopes of very small pow This danger is as great in other directions spectroscopy. A little examination of Dr. Hugg address will show what a great part electric playing in all these investigations. He sug the light of a comet is due to disruptive ele discharges, and that these discharges may be as and possibly increased by the action of the violet part of the sun's light. "Lenard and have shown that ultra-violet light can produ discharge from a negatively electrified piece of m while Hallwachs and Righi have shown fu that ultra-violet light can even charge posit an unelectrified piece of metal." Further, suggestion that the sun's corona, as well as the of comets, is once more distinctly set forth as d electricity, and "further, if such a force exist at sun, the changes of terrestrial magnetism ma due to direct electric action, as the earth m through lines of inductive force." No doubt Huggins has thoroughly convinced himself that "lines of inductive force" do permeate s although to the ordinary mind the "circuit" thr which these lines must act is not easily trace Taking one hemisphere of the sun as the sta pole, where is the circuit by which the close again on the starting point? They cert do not start from the sun and radiate

ace. Many physicists look upon electricity as a radiant something; they cannot show one single experiment in support of their views, but always suppose something of the nature of an absurdity, in a pole being at an infinite distance from another pole—in fact, in such a position that no electrical phenomena could result. We are digressing, however, from the presidential address, which indicates not only the recent work done in celestial physics, but the vast amount of work still open to the earnest student, concluding with the pregnant statement that though the "pace of the race is gaining, 'the goal' is not and never will be in sight."

SECTION-PRESIDENTS: MATHEMATICAL—MECHANICAL.

Prof. Lodge, in his address to Section A, goes for a national laboratory. He does not believe much in individual or amateur efforts, but thinks scientific investigation should progress like an invading army. The rank and file require to be properly generalled and led. No doubt a national laboratory is theoretically a nice thing, especially for those who could pose as generals—give their orders, and see someone else do the work. The members of the younger generation would work hard; would move heaven and earth to obtain a chair in the laboratory. The nation is a good paymaster, but seldom a hard taskmaster. Who should decide as to the eligibility of candidates? And who should decide as to the value of the orders given and the work carried out? The real investigator is almost always working alone, along a new line, and time only can show the value of such work. Prof. Lodge says the question of a fifth or sixth decimal is very legitimate, and so it is; but it is of no earthly service to the nation as a nation, and national money ought not to be expended on such a pursuit. The President of Section G discourses upon mining operations, gives a good deal of information as to recent progress, and concludes that electrical apparatus "will eventually become the principal agent in underground mechanical operations."

TRANSMISSION OF POWER AT FRANKFORT.

We are advised that the plant for the transmission of power at Frankfort is now complete, and reports of the starting and tests are expected at once. The great feature of this enterprise is its entire novelty from two points—the transmission of large powers to such a long distance at enormous pressure, and the actual use of the rotary-current machines. The falls of the Neckar at Lauffen, in Wurtemberg, are at a distance of 180 kilometres, nearly 110 miles, from Frankfort. Over this distance three stout telegraph wires are carried on poles fitted with insulators furnished with oil insulation. The original poles first used at Oerlikon will be seen at the exhibition. Along these wires, electricity at a pressure of about 25,000 volts is to be transmitted in alternating currents whose phases or pulsations are so arranged as to overlap or interlink with each other, forming in the machine at the receiving end a rotating magnetic polarity by which the electric power can be converted into mechanical force and so distributed. The generator of this installation, which we shall illustrate next week, consists of a 300-h.p. dynamo of the new three-phase system, constructed by the Oerlikon Company, of Zurich, in conjunction with the Allgemeine Company, of Berlin. On August 15, the date fixed by contract, the apparatus was handed over to the Board of Management of the exhibition.

The conductors required for the transmission of the current have been run by the German Imperial Postal Administration, and the Royal Wurtemberg Telegraph Authorities. The machinery at Lauffen is already in working order, and next week the measurements and tests of strength prescribed by the Imperial and Wurtemberg Governments will take place. It is probable, therefore, that by the end of next week the transmission of electric force from Lauffen to Frankfort can be regularly begun. The power will be used as follows: Of the 300 h.p., more or less, that is received, 100 h.p. will be used to pump water to supply an enormous waterfall in the exhibition grounds, 100 h.p. will be used for lighting purposes, and the remainder will be distributed in power transmission. The experiment is attracting the keenest interest in scientific circles and practical circles, as it is abundantly felt that the practical demonstration of the utilisation of natural forces at such distances from the source, opens almost undreamt-of possibilities to industry in the future.

VIBRATIONS OF CONDUCTORS.

A thin metallic wire stretched between two supports, one of which is furnished with a tightening winch to regulate the tension, when traversed by a *continuous* current, begins to vibrate, says M. D. Hurmuzescu in *Comptes Rendus*. The amplitude of the vibrations, at first very feeble, gradually increases and rapidly attains a maximum, which is preserved as long as the current passes, provided that the surrounding conditions remain the same, or at least do not abruptly change. The vibrations may thus continue indefinitely; they cease in a few seconds when the current ceases.

For a determined electric pressure, the amplitude of the vibrations seem to depend (according to the experiments hitherto made) upon the difference of temperature of the wire and the surrounding medium. As this difference of temperature depends on the strength of current for the same wire, the phenomenon should vary with the strength of current.

The explanation seems to result from the exchange of heat between the wire and the surrounding medium, and constitutes a veritable "thermic motor," in which the energy expended is furnished by the current, and the principle of conservation of energy can be applied thereto.

Any cause which will change in any way the mode of this exchange will modify the phenomenon. More particularly, it can be foreseen that the finer the wire the more rapid will be the vibration, and this is confirmed by experiment. I have repeated the experiment with wires of different kinds, and have found that the vibrations always maintain the same character. If the wire is enclosed within a glass tube the vibrations are regular, as the wire is sheltered from movements of the air. Closing the two

ends does not change the rapidity. I hope to present later the laws of the phenomenon with regard to the tension of the wire, the difference of temperatures between the wire and the surrounding medium, and the manner in which the exchange of heat is effected between the two sources.

EDISON DYNAMO AND MOTOR.

(Concluded from page 134.)

The steel armature shaft is 16½in. long and ½in. in diameter at the journals, and $\frac{11}{16}$in. in diameter between the journals. The larger part of the shaft is 9½in. long.

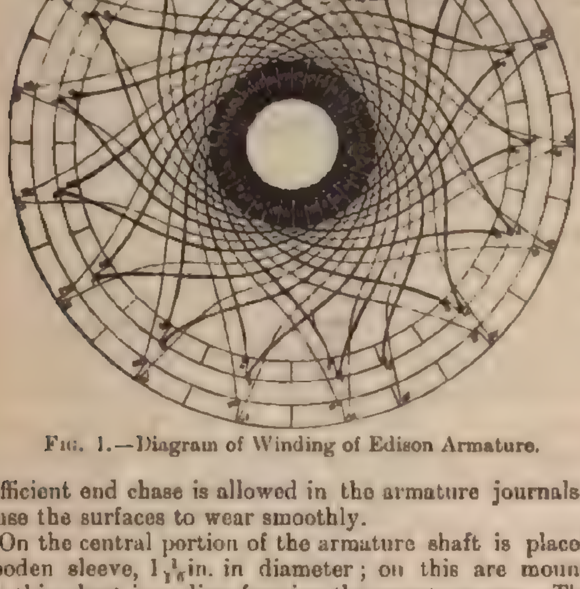

Fig. 1.—Diagram of Winding of Edison Armature.

Sufficient end chase is allowed in the armature journals to cause the surfaces to wear smoothly.

On the central portion of the armature shaft is placed a wooden sleeve, $1\frac{1}{16}$in. in diameter; on this are mounted the thin sheet iron discs forming the armature core. These discs are 2½in. in diameter. They are arranged in series of five, with tissue paper between the discs, and between the series of five are placed several thicknesses of paper.

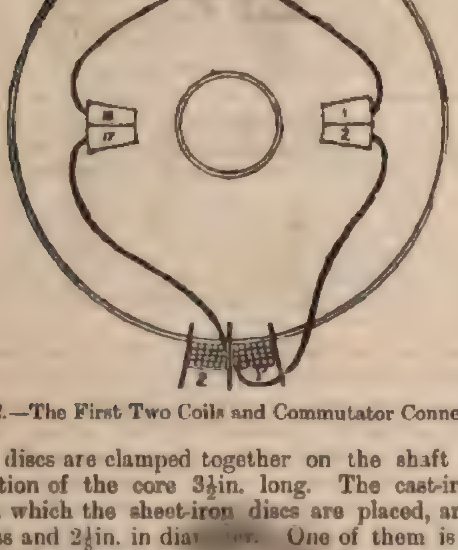

Fig. 2.—The First Two Coils and Commutator Connections.

Enough discs are clamped together on the shaft to make this portion of the core 3½in. long. The cast-iron discs, between which the sheet-iron discs are placed, are ¼in. in thickness and 2½in. in dia[illegible] One of them is fixed on the shaft, the other being [illegible]e by a hexagonal nut screwe[illegible]haft. T[illegible]s have their [illegible]ter corners [illegible]d in th[illegible] are form[illegible] equi-di[illegible]ts, [illegible] hese sli[illegible] inserted[illegible]d [illegible] he diff[illegible] pairs of [illegible]

It is impossible to describe the Edison winding w[illegible] depending mainly on the diagrams, Figs. 1 and 2. T[illegible] are two series of coils; that is to say, there are two [illegible] each division of the armature. There are 32 bar[illegible] commutator, which are numbered consecutively fro[illegible] to 32.

The armature core and shaft are thoroughly insulated [illegible] means of paper coated with an adhesive varnish. [illegible] string ribbon is wound on the face of the core as a f[illegible] protection.

The wire used on the armature is No. 21 copper [illegible] double covered, the inner covering being of silk, the [illegible] of cotton.

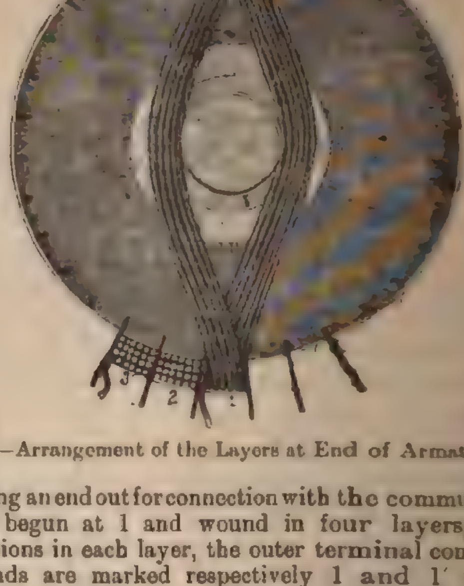

Fig. 3.—Arrangement of the Layers at End of Armature [illegible]

Leaving an end out for connection with the commutato[illegible] No. 1 is begun at 1 and wound in four layers, with [illegible] convolutions in each layer, the outer terminal coming [illegible] These ends are marked respectively 1 and 1′ in su[illegible] manner as to avoid any possibility of the detachme[illegible] the marks. If this caution is observed, much trouble [illegible] be avoided. A good way to mark them is to place a [illegible] of parchment, or parchment paper, on each end of the [illegible] with the number marked on.

After winding coil No. 1 the armature is turned half [illegible] over, and coil No. 2 is wound and marked in the same [illegible]

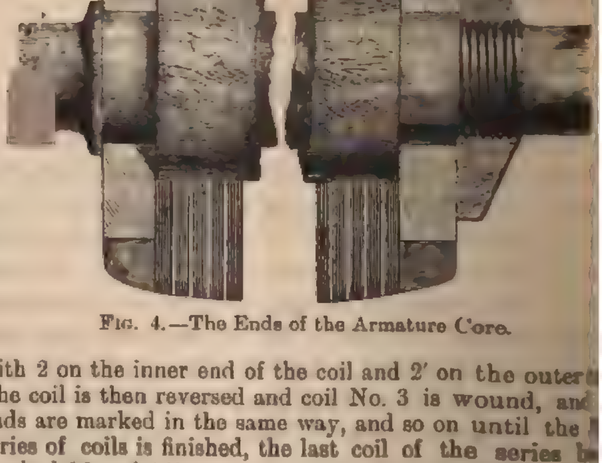

Fig. 4.—The Ends of the Armature Core.

with 2 on the inner end of the coil and 2′ on the outer [illegible] The coil is then reversed and coil No. 3 is wound, and [illegible] ends are marked in the same way, and so on until the [illegible] series of coils is finished, the last coil of the series b[illegible] marked 16 and 16′.

The first coil of the outer series is No. 17-17′. Th[illegible] wound on the top of coil No. 1. The armature is tu[illegible] [illegible]r, and No. 18 is wound on the top of No. 2, and [illegible] [illegible]ll of the outer coils are in place.

[illegible] winding, the inner end of each wire is wra[illegible]

e string ribbon to a point within the end of the arma-ore, and it is further protected by a wrapping of thin ive tape. The outer end of the coil is covered in the way.

›ut 3lb. of No. 21 wire are required for the armature. ›ngth of wire in the first inner coil is 26ft. 6in. The ı of wire in the last outer coil is 35ft.

› commutator cylinder is formed of 32 bronze bars g bevelled ends and radial arms for receiving the These bars are clamped in position on a sleeve g an under-cut flange, by a countersunk washer and a ›rewed on the sleeve. Mica is inserted between the utator bars, between the bars and the sleeve, and en the ends of the bars and the flange and the washer. adial arms extending from the commutator bars each a slot in the end for receiving the terminals of the

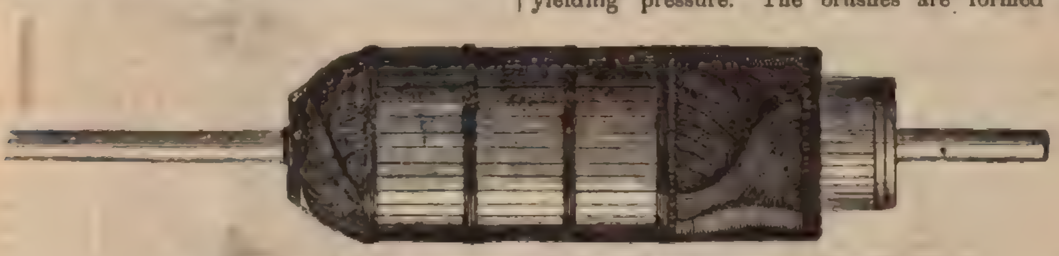

Fig. 5.—The Armature with Parts Broken away.

› coil terminals are arranged in groups of 16, the of each group being parallel. The terminals are d around and attached to commutator bars, which are 45deg. from the planes of the coils to which they g, thus making the winding more symmetrical, and at me time permitting of a better arrangement of the es

› coil terminals are inserted in the slots of the arms commutator bars, and soldered with soft solder, the ctions being made in accordance with the diagram,

› wires, where they cross at the back and front end › armature, are separated by sheets of mica. Where inding crosses at the rear end of the armature the are spread out so that they are only one layer deep. ›en the winding of a coil is finished, the terminal is ed by stout threads inserted in the coil before ng the last three convolutions, and tied after the coil ıplete.

Fig. 6.—The Brush Yoke.

ulcanised fibre collar, a little larger in diameter than ›mmutator, is slipped over the commutator bars and against the radial arms of the bars, as shown. The of the collar is grooved and a canvas cover is ›d to the collar by tying it in the groove. It is then over the terminals and fastened by the first ring of g wire on the armature. At the opposite end of the are a similar collar and cover is provided.

›re covering the terminals with the canvas they are l with twine, to give the end of the armature a etrical shape. The winding is varnished with shellac its cover is applied, and the cover is varnished after ›cured in place.

The binding rings are formed of brass wire, wound tightly over a layer of mica interposed between the wire and the binding. The binding wire is secured by clips and soft soldering.

The brush yoke is provided with wooden handle by which it may be moved, and a binding screw by which it is clamped in the position of use. In mortises in the ends of the yoke are placed insulating blocks, in which are inserted the brush-holding studs. These studs are each provided with a nut for clamping the brush-holder cables which communicate with the leads at the side of the pole-pieces.

On each brush-holding stud is placed a sleeve fastened with a set screw, also a loose sleeve connected with the fast sleeve by a spiral spring concealed within it. The loose sleeve is furnished with a brush clamp for holding the brush, which bears on the commutator cylinder with a yielding pressure. The brushes are formed of spring copper wires fastened together at their outer ends with soft solder. A jig goes with each machine for clamping the brush and guiding the file while renewing the brush ends.

The speed of the motor on a 125-volt circuit is 2,400 revolutions per minute. The speed at which the armature is to be driven in order to generate a current having an E.M.F. of 125 volts is 2,730 revolutions per minute.

Since the first part of this article appeared in our issue of July 25, we have received a letter from the Edison General Electric Company, stating that the machine here described—according to the new rating, which went into effect June 15—is a 0 5 kilowatt machine, which, when used as a generator, for supplying lights, will generate sufficient current to bring to full candle-power nine 16-c.p. 112-volt lamps, and when used for power it is a ½-h.p. motor at a rated volt. It is guaranteed to give 0·47 h.p. at ⅞ of its rated volts.

We are also reminded by this letter of the fact we neglected to state in our former article, which is that

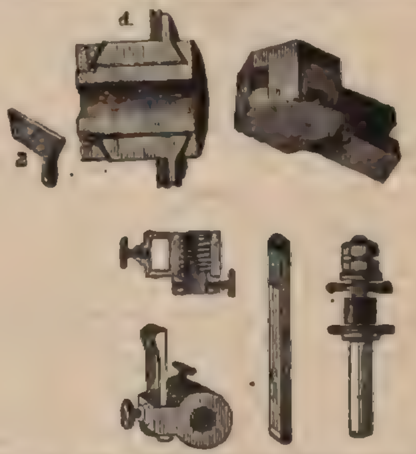

Fig. 7.—Details of Brush Holders and Commutator Cylinder.

this form of machine is a type which was brought out in 1885, and is known as the Standard Edison machine, which is made in several sizes. Each size is identical, in its general construction, with the machine described, and any of the machines can be used either as dynamo or motor.—*Scientific American.*

The Hampstead Vestry has resolved to apply to the Board of Trade for a provisional order authorising it to introduce electric lighting for public and private uses in the borough of Hampstead. The Vestry has, however, not yet decided whether to carry out the lighting itself or to place it in the hands of an electrical company.

THE BRITISH ASSOCIATION AT CARDIFF.

The sixty-first meeting of the British Association for the Advancement of Science was opened at Cardiff on Wednesday night, when William Huggins, Esq., D.C.L., LL.D., etc., the president for the ensuing year, delivered his presidential address. Sir Frederick Abel, the past-president, first addressed some congratulatory remarks to the Marquis of Bute, who, in his capacity of mayor, welcomed the association to Cardiff. Dr. Huggins was then formally introduced, and was cordially greeted by a large and fashionable audience assembled to hear his presidential address on astronomical science. Amongst the audience were Prof. Max Müller, Sir Fred. Bramwell, Sir Douglas Galton, Sir Benj. Baker, most of the presidents of the sections, Prof. Newton, Mr. W. H. Preece, Prof. Rücker, and many other well-known scientific men.

PRESIDENTIAL ADDRESS BY WILLIAM HUGGINS, Esq., D.C.L. (Oxon.), LL.D. (Cantab., Edin., et Dublin.), Ph.D. (Lugd. Bat.), F.R.S., F.R.A.S., Hon. F.R.S.E., etc., Correspondant de l'Institut de France.

It is now many years since this association has done honour to the science of astronomy in the selection of its president.

Since Sir George Airy occupied the chair in 1851, and the late Lord Wrottesley nine years later in 1860, other sciences have been represented by the distinguished men who have presided over your meetings.

The very remarkable discoveries in our knowledge of the heavens which have taken place during this period of 30 years—one of amazing and ever-increasing activity in all branches of science—have not passed unnoticed in the addresses of your successive presidents; still, it seems to me fitting that I should speak to you to-night chiefly of those newer methods of astronomical research which has led to those discoveries, and which have become possible by the introduction since 1860 into the observatory of the spectroscope and the modern photographic plate.

In 1866 I had the honour of bringing before this association, at one of the evening lectures, an account of the first-fruits of the novel and unexpected advances in our knowledge of the celestial bodies which followed rapidly upon Kirchoff's original work on the solar spectrum and the interpretation of its lines.

Since that time a great harvest has been gathered in the same field by many reapers. Spectroscopic astronomy has become a distinct and acknowledged branch of the science, possessing a large literature of its own and observatories specially devoted to it. The more recent discovery of the gelatine dry plate has given a further great impetus to this modern side of astronomy, and has opened a pathway into the unknown of which even an enthusiast 30 years ago would scarcely have dared to dream.

In no science, perhaps, does the sober statement of the results which have been achieved appeal so strong to the imagination, and make so evident the almost boundless powers of the mind of man. By means of its light alone to analyse the chemical nature of a far distant body; to be able to reason about its present state in relation to the past and future; to measure within an English mile or less per second the otherwise invisible motion which it may have towards or from us; to do more, to make even that which is darkness to our eyes light, and from vibrations which our organs of sight are powerless to perceive to evolve a revelation in which we see mirrored some of the stages through which the stars may pass in their slow evolutional progress—surely the record of such achievements, however poor the form of words in which they may be described, is worthy to be regarded as the scientific epic of the present century.

I do not purpose to attempt a survey of the progress of spectroscopic astronomy from its birth at Heidelberg in 1859, but to point out what we do know at present, as distinguished from what we do not know, of a few only of its more important problems, giving a prominent place, in accordance with the traditions of this chair, to the work of the last year or two.

In the spectroscope itself advances have been made by Lord Rayleigh by his discussions of the theory of the instrument, and by Prof. Rowland in the construction of concave gratings.

Lord Rayleigh has shown that there is not the necessary connection, sometimes supposed, between dispersion and resolving power, as besides the prism, or grating, other details of construction and of adjustment of a spectroscope must be taken into account.

The resolving power of the prismatic spectroscope is proportional to the length of path in the dispersive medium. For the heavy flint glass used in Lord Rayleigh's experiments the thickness necessary to resolve the sodium lines came out 1·02 cm. If this be taken as a unit, the resolving power of a prism of similar glass will be in the neighbourhood of the sodium lines equal to the number of centimetres of its thickness. In other parts of the spectrum the resolving power will vary inversely as the third power of the wave-length, so that it will be eight times as great in the violet as in the red. The resolving power of a spectroscope is therefore proportional to the total thickness of the dispersive material in use, irrespective of the number, the angles, or the setting of the separate prisms into which, for the sake of convenience, it may be distri[buted].

The resolving power of a grating depends upon [the] number of lines on its surface, and the order of spectr[um], about 1,000 lines being necessary to resolve the sodium l[ines in the] first spectrum.

As it is often of importance in the record of observati[ons] the efficiency of the spectroscope with which they w[ere] Prof. Schuster has proposed the use of a unit of purity ... of resolving power, for the full resolving power of a sp[ectroscope] is realised in practice only when a sufficiently narrow sl[it]. The unit of purity also is to stand for the separation of ... differing by one-thousandth of their own wave-length—a... separation of the sodium pair at D.

A further limitation may come in from the physiolog[ical] that, as Lord Rayleigh has pointed out, the eye wh[en] aperture is used is not a perfect instrument. If we wis[h] the full resolving power of a spectroscope, therefore, the ... beam must not be larger than about one-third of the ope[ning of] the pupil.

Up to the present time the standard of reference for ... spectroscopic work continues to be Angstrom's map of ... spectrum, and his scale based upon his original determ[inations of] absolute wave-length. It is well known, as was pointe[d out by] Thalén in his work on the spectrum of iron in ... Angstrom's figures are slightly too small, in consequenc[e of an] error existing in a standard metre used by him. The c... for this have been introduced into the tables of the wa[ve-lengths] of terrestrial spectra collected and revised by a committe[e of the] association from 1885 to 1887. Last year the committee ... table of corrections to Rowland's scale.

The inconvenience caused by a change of standard scal[e is, for] a time at least, considerable; but there is little doubt tha[t in the] near future Rowland's photographic map of the solar sp[ectrum] and his scale based on the determinations of absolute wav[e-lengths] by Pierce and Bell, or the Potsdam scale based on original d[etermi]nations by Müller and Kempf, which differs very slightly ... will come to be exclusively adopted.

The great accuracy of Rowland's photographic map is du[e] to the introduction by him of concave gratings, and of a ... for their use, by which the problem of the determination of ... wave-lengths is simplified to measures of coincidences of ... in different spectra by a micrometer.

The concave grating and its peculiar mounting, in w[hich no] lenses or telescope are needed, and in which all the spectr[a] focus together, formed a new departure of great importan[ce in the] measurement of spectral lines. The valuable method o[f photo]graphic sensitisers for different parts of the spectrum has ... Prof. Rowland to include in his map the whole visi[ble] spectrum, as well as the ultra violet portion as far as it ... through our atmosphere. Some recent photographs of t[he red end of the] spectrum, which include A, by Mr. George Higgs, are ... technical beauty.

During the past year the results of three independent re[searches] have appeared, in which the special object of the obser[vers has] been to distinguish the lines which are due to our atmosph[ere from] those which are truly solar—the maps of M. Thollon, whic[h, owing] to his lamented death just before their final completio[n, have] assumed the character of a memorial of him, maps by Dr. ... and sets of photographs of a high and a low sun by Mr. M...

At the meeting of this association in Bath, M. Janssen ... account of his own researches on the terrestrial lines of t[he solar] spectrum, which owe their origin to the oxygen of our atm[osphere]. He discovered the remarkable fact that while one class o[f bands] varies as the density of the gas, other diffuse bands vary ... square of the density. These observations are in accorda[nce with] the work of Egoroff and of Olszewski, and of Liveing and ... on condensed oxygen. In some recent experiments Ol[szewski], with a layer of liquid oxygen 30 millimetres thick, saw, ... four other bands, the band coincident with Fraunhofer['s] ... remarkable instance of the persistence of absorption th[rough a] great range of temperature. The light which passed thro[ugh the] liquid oxygen had a light blue colour resembling that of t[he sky].

Of not less interest are the experiments of Knut Ån[gström], which show that the carbonic acid and aqueous vapour [of the] atmosphere reveal their presence by dark bands in the ... infra-red region, at the positions of bands of emission ... substances.

It is now some 30 years since the spectroscope gave us [for the] first time certain knowledge of the nature of the heavenly [bodies], and revealed the fundamental fact that terrestrial matt[er is not] peculiar to the solar system, but is common to all the sta[rs that] are visible to us.

In the case of a star such as Capella, which has a ... almost identical with that of the sun, we feel justified [in con]cluding that the matter of which it is built up is similar, ... its temperature is also high, and not very different from t[he solar] temperature. The task of analysing the stars and nebulæ ..., however, one of very great difficulty when we have to ... spectra differing from the solar type. We are thrown ba[ck upon] the laboratory for the information necessary to enable us ... pret the indications of the spectroscope as to the chemical ..., the density and pressure, and the temperature of the ... masses.

What the spectroscope immediately reveals to us are th[e waves] which were set up in the ether filling all interstellar spac[e, years] or hundreds of years ago, by the motions of the molecul[es of the] celestial substances. As a rule, it is only when a body is ... and sufficiently hot that the motions within its molec[ules] produce bright lines and a corresponding absorption .... spectra of the heavenly bodies are indeed to a great ... absorption spectra, but we have usually to study them thr...

nding emission spectra of bodies brought into the gaseous
l rendered luminous by means of flames or of electric dis-
In both cases, unfortunately, as has been shown recently
s, Liveing and Dewar, Wullner, E. Wiedemann, and
here appears to be no certain direct relation between the
s radiation as shown in the spectroscope and the tempera-
he flame, or of the gaseous contents of the vacuum tube—
in the usual sense of the term as applied to the mean
f all the molecules. In both cases, the vibratory motions
he molecules to which their luminosity is due are almost
much greater than would be produced by encounters of
s having motions of translation no greater than the
motions which characterise the temperature of the gases
le. The temperature of the vacuum tube through which
ic discharge is taking place may be low, as shown by a
eter, quite apart from the consideration of the extreme small-
he mass of gas, but the vibrations of the luminous molecules
violent in whatever way we suppose them to be set up by
arge; if we take Schuster's view that comparatively few
s are carrying the discharge, and that it is to the fierce
rs of these alone that the luminosity is due, then, if all
cules had similar motions, the temperature of the gas
e very high.

flames where chemical changes are in progress, the vibra-
tions of the molecules, which are luminous, may be, in
on with the energy set free in these changes, very diffe-
n those corresponding to the mean temperature of the

the ordinary conditions of terrestrial experiments, there-
e temperature or the mean *vis viva* of the molecules may
direct relation to the total radiation, which, on the other
the sum of the radiation due to each luminous molecule.
phenomena have recently been discussed by Ebert from
dpoint of the electromagnetic theory of light.

great caution is therefore called for when we attempt to
y the aid of laboratory experiments to the temperature of
enly bodies from the radiation, especially on the reasonable
ion that in them the luminosity is not ordinarily associated
mical changes or with electrical discharges, but is due to
glowing from the ultimate conversion into molecular
f the gravitational energy of shrinkage.

scent paper, Stas maintains that electric spectra are to be
l as distinct from flame spectra; and, from researches of
that the pairs of lines of the sodium spectrum other than
roduced only by disruptive electric discharges. As these
lines are found reversed in the solar spectrum, he con-
hat the sun's radiation is due mainly to electric dis-
But Wolf and Diacon, and later, Watts, observed the
irs of lines of the sodium spectrum when the vapour was
bove the ordinary temperature of the Bunsen flame.
, Liveing and Dewar saw easily, besides D, the citron
n pairs and sometimes the blue pair and the orange pair,
ydrogen charged with sodium vapour was burning at
pressures in oxygen. In the case of sodium vapour,
, and presumably in all other vapours and gases, it is a
f indifference whether the necessary vibratory motion of
cules is produced by electric discharges or by flames. The
of lines in the solar spectrum, which we can only produce
lly, is an indication, however, as Stas points out, of the
perature of the sun.

ust not forget that the light from the heavenly bodies may
f the combined radiations of different layers of gas at
temperatures, and possibly be further complicated to an
extent by the absorption of cooler portions of gas outside.
s caution is needed if we endeavour to argue from the
ng of lines and the coming in of a continuous spectrum as
lative pressure of the gas in the celestial atmospheres.
ne hand, it cannot be gainsaid that in the laboratory the
of the lines in a Plucker's tube follows upon increasing
ity of the residue of hydrogen in the tube, when the vibra-
more frequently disturbed by fresh encounters, and that
ning of the sodium lines in a flame at ordinary pressure
ed by an increase of the quantity of sodium in the flame;
doubtful if pressure, as distinguished from quantity,
duce an increase of the breadth of the lines. An indi-
olecule of sodium will be sensibly in the same condition,
ing the relatively enormous number of the molecules of
gases, whether the flame is scantily or copiously fed with
um salt. With a small quantity of sodium vapour the
will be feeble except near the maximum of the lines;
wever, the quantity is increased the comparative trans-
on the sides of the maximum will allow the light from the
l molecules met with in the path of the visual ray to
n the radiation of the molecules farther back, and so
the breadth of the lines.

gaseous mixture it is found, as a rule, that at the same
or temperature, as the encounters with similar molecules
ewer, the spectral lines will be affected as if the body
rved under conditions of reduced quantity or temperature.
r recent investigation of the spectroscopic behaviour of
der various pressures up to 40 atmospheres, Profs. Liveing
ar have come to the conclusion that though the prominent
f the light emitted by flames at high pressure appears to
ng continuous spectrum, there is not the slightest indica-
this continuous spectrum is produced by the broadening
nes of the same gases at low pressure. On the contrary,
tric observations of the brightness of the continuous spec-
the pressure is varied, show that it is mainly produced
utual action of the molecules of a gas. Experiments on
m spectrum were carried up to a pressure of 40 atmo-
spheres without producing any definite effect on the width of the lines which could be ascribed to the pressure. In a similar way the lines of the spectrum of water showed no signs of expansion up to 12 atmospheres; though more intense than at ordinary pressure, they remained narrow and clearly defined.

It follows, therefore, that a continuous spectrum cannot be considered, when taken alone, as a sure indication of matter in the liquid or the solid state. Not only, as in the experiments already mentioned, such a spectrum may be due to gas when under pressure, but, as Maxwell pointed out, if the thickness of a medium, such as sodium vapour, which radiates and absorbs different kinds of light, be very great, and the temperature high, the light emitted will be of exactly the same composition as that emitted by lampblack at the same temperature, for the radiations, which are feebly emitted, will be also feebly absorbed, and can reach the surface from immense depths. Schuster has shown that oxygen, even in a partially exhausted tube, can give a continuous spectrum when excited by a feeble electric discharge.

Compound bodies are usually distinguished by a banded spectrum; but, on the other hand, such a spectrum does not necessarily show the presence of compounds—that is, of molecules containing different kinds of atoms—but simply of a more complex molecule, which may be made up of similar atoms, and be therefore an allotropic condition of the same body. In some cases, for example, in the diffuse bands of the absorption spectrum of oxygen, the bands may have an intensity proportional to the square of the density of the gas, and may be due either to the formation of more complex molecules of the gas with increase of pressure, or it may be to the constraint to which the molecules are subject during their encounters with one another.

It may be thought that at least in the coincidences of bright lines we are on the solid ground of certainty, since the length of the waves set up in the ether by a molecule, say, of hydrogen, is the most fixed and absolutely permanent quantity in nature, and is so of physical necessity, for with any alteration the molecule would cease to be hydrogen.

Such would be the case if the coincidence were certain; but an absolute coincidence can be only a matter of greater or less probability, depending on the resolving power employed, on the number of the lines which correspond and on their characters. When the coincidences are very numerous, as in the case of iron and the solar spectrum, or the lines are characteristically grouped, as in the case of hydrogen and the solar spectrum, we may regard the coincidence as certain; but the progress of science has been greatly retarded by resting important conclusions upon the apparent coincidence of single lines, in spectroscopes of very small resolving power. In such cases, unless other reasons supporting the coincidence are present, the probability of a real coincidence is almost too small to be of any importance, especially in the case of a heavenly body which may have a motion of approach or of recession of unknown amount.

But even here we are met by the confusion introduced by multiple spectra, corresponding to different molecular groupings of the same substance; and, further, to the influence of substances in vapour upon each other; for when several gases are present together, the phenomena of radiation and reversal by absorption are by no means the same as if the gases were free from each other's influence, and especially is this the case when they are illuminated by an electric discharge.

I have said as much as time will permit, and I think indeed sufficient, to show that it is only by the laborious and slow process of most cautious observation that the foundations of the science of celestial physics can be surely laid. We are at present in a time of transition when the earlier and, in the nature of things, less precise observations are giving place to work of an order of accuracy much greather than was formerly considered attainable with objects of such small brightness as the stars.

The accuracy of the earlier determininations of the spectra of the terrestrial elements are in most cases insufficient for modern work on the stars as well as on the sun. They fall much below the scale adopted in Rowland's map of the sun, as well as below the degree of accuracy attained at Potsdam by photography in a part of the spectrum for the brighter stars. Increase of resolving power very frequently breaks up into groups, in the spectra of the sun and stars, the lines which had been regarded as single, and their supposed coincidences with terrestrial lines fall to the ground. For this reason many of the early conclusions, based on observation as good as it was possible to make at the time with the less powerful spectroscopes then in use, may not be found to be maintained under the much greater resolving power of modern instruments.

The spectroscope has failed as yet to interpret for us the remarkable spectrum of the aurora borealis. Undoubtedly, in this phenomenon portions of our atmosphere are lighted up by electric discharges; we should expect, therefore, to recognise the spectra of the gases known to be present in it. As yet we have not been able to obtain similar spectra from these gases artificially, and especially we do not know the origin of the principal line in the green, which often appears alone, and may have therefore an origin independent of that of the other lines. Recently the suggestion has been made that the aurora is a phenomenon produced by the dust of meteors and falling stars, and that near positions of certain auroral lines to lines or flutings of manganese, lead, barium, thallium, iron, etc., are sufficient to justify us in regarding meteoric dust in the atmosphere as the origin of the auroral spectrum. Liveing and Dewar have made a conclusive research on this point, by availing themselves of the dust of excessive minuteness thrown off from the surface of electrodes of various metals and meteorites by a disruptive discharge, and carried forward into the tube of observation by a more or less rapid current of air or other gas. These experiments prove that metallic dust,

however fine, suspended in a gas will not act like gaseous matter in becoming luminous with its characteristic spectrum in an electric discharge, similar to that of the aurora. Prof. Schuster has suggested that the principal line may be due to some very light gas which is present in too small a proportion to be detected by chemical analysis or even by the spectroscope in the presence of the other gases near the earth, but which at the height of the auroral discharges is in a sufficiently greater relative proportion to give a spectrum. Lemstrom, indeed, states that he saw this line in the silent discharge of a Holtz machine on a mountain in Lapland. The lines may not have been obtained in our laboratories from the atmospheric gases, on account of the difficulty of reproducing in tubes with sufficient nearness the conditions under which the auroral discharges take place.

In the spectra of comets the spectroscope has shown the presence of carbon presumably in combination with hydrogen, and also sometimes with nitrogen; and in the case of comets approaching very near the sun, the lines of sodium, and other lines which have been supposed to belong to iron. Though the researches of Prof. H. A. Newton and Prof. Schiaparelli leave no doubt of the close connection of comets with corresponding periodic meteor swarms, and therefore of the probable identity of cometary matter with that of meteorites, with which the spectroscopic evidence agrees, it would be perhaps unwise at present to attempt to define too precisely the exact condition of the matter which forms the nucleus of the comet. In any case the part of the light of the comet which is not reflected solar light can scarcely be attributed to a high temperature produced by the clashing of separate meteoric stones set up within the nucleus by the sun's disturbing force. We must look rather to disruptive electric discharges produced probably by processes of evaporation due to increased solar heat, which would be amply sufficient to set free portions of the occluded gases into the vacuum of space. May it be that these discharges are assisted, and indeed possibly increased, by the recently discovered action of the ultra-violet part of the sun's light? Lenard and Wolf have shown that ultra-violet light can produce a discharge from a negatively electrified piece of metal, while Hallwachs and Righi have shown further that ultra-violet light can even charge positively an unelectrified piece of metal. Similar actions on cometary matter, unscreened as it is by an absorptive atmosphere, at least of any noticeable extent, may well be powerful when a comet approaches the sun, and help to explain an electrified condition of the evaporated matter which would possibly bring it under the sun's repulsive action. We shall have to return to this point in speaking of the solar corona.

A very great advance has been made in our knowledge of the constitution of the sun by the recent work at the Johns Hopkins University by means of photography and concave gratings, in comparing the solar spectrum, under great resolving power, directly with the spectra of the terrestrial elements. Prof. Rowland has shown that the lines of 36 terrestrial elements at least are certainly present in the solar spectrum, while eight others are doubtful. Fifteen elements, including nitrogen as it shows itself under an electric discharge in a vacuum tube, have not been found in the solar spectrum. Some 10 other elements, inclusive of oxygen, have not yet been compared with the sun's spectrum.

Rowland remarks that of the 15 elements named as not found in the sun, many are so classed because they have few strong lines, or none at all, in the limit of the solar spectrum as compared by him with the arc. Boron has only two strong lines. The lines of bismuth are compound and too diffuse. Therefore even in the case of these 15 elements there is little evidence that they are really absent from the sun.

It follows that if the whole earth were heated to the temperature of the sun, its spectrum would resemble very closely the solar spectrum.

Rowland has not found any lines common to several elements, and in the case of some accidental coincidences, more accurate investigation reveals some slight difference of wave-length or a common impurity. Further, the relative strength of the lines in the solar spectrum is generally, with a few exceptions, the same as that in the electric arc, so that Rowland considers that his experiments show "very little evidence" of the breaking up of the terrestrial elements in the sun.

Stas in a recent paper gives the final results of 11 years of research on the chemical elements in a state of purity, and on the possibility of decomposing them by the physical and chemical forces at our disposal. His experiments on calcium, strontium, lithium, magnesium, silver, sodium, and thallium, show that these substances retain their individuality under all conditions, and are unalterable by any forces that we can bring to bear upon them.

(To be continued.)

ADDRESS TO THE MATHEMATICAL AND PHYSICAL SECTION OF THE BRITISH ASSOCIATION.

BY PROF. OLIVER J. LODGE, D.SC., LL.D., F.R.S., PRESIDENT OF THE SECTION.

During the past yea[illegible] or four events call for special mention in an annual d[illegible] this kind by a physicist.

O[illegible] Faraday [illegible] was kept in [illegible]appy and si[illegible] by a co[illegible]ing in th[illegible] so long as [illegible]'s work [illegible]s callin[illegible]on to the[illegible]ent o[illegible] him.

Another is the decease of the veteran Wilhelm Weber, [illegible] originators of that absolute system of measurement wh[illegible] still ungrasped in its simplicity and completeness by the [illegible] of men engaged in practice, nor even, I fear, wholly [illegible] by some of those engaged in university teaching, has [illegible] much, and is destined to do still more, for the [illegible] physical science, and for a thorough comprehension of [illegible] and its limitations.

A third event of importance during the year is the dis[illegible] America of a binary system of stars, revolving round [illegible] with grotesque haste, and with a proximity to each other [illegible] to render their ordinary optical separation quite [illegible] Ideas concerning the future of such systems, if, as seems [illegible] their revolution period is shorter than their axial per[illegible] readily suggest themselves, in accordance with the [illegible] elaborated by Prof. George Darwin. The subject more [illegible] belongs to our president, but I may parenthetically excl[illegible] singular absurdity of the notion which was once propound[illegible] philosopher, that motion of stars in our line of sight must [illegible] remain unknown to us; when the mere time of revol[illegible] satellite, compared with its distance from its central [illegible] theoretically sufficient to give us information on this [illegible] a matter of pedagogy it is convenient to observe that the [illegible] called Doppler's, which is generally known to apply [illegible] periodic disturbances called light and sound, applies equ[illegible] periodic occurrences; and that the explanation of ano[illegible] Jupiter's first satellite by Roemer may be regarded as an [illegible] of Doppler's principle.* Any discrepancy between the [illegible] and the calculated times of revolution of stars round ea[illegible] can possibly be explained by a relative motion between u[illegible] pair of bodies along the line of sight.

If our text-books clearly recognised this, we should no[illegible] find examination candidates asserting that the apparent [illegible] revolution of a satellite of Jupiter depends on the distance [illegible] earth from that planet, instead of on the speed. I should [illegible] be sorry to be judged by the performance of my own studen[illegible] I fear that many of the less obvious mistakes made by [illegible] trained examination candidates are more directly traceable [illegible] teachers than some of us as teachers would like to admit.

The change in the refrangibility of light by reason of the [illegible] of its source, though commonplace enough now, was [illegible] regarded as too small to be observed, and one or two [illegible] directed to detecting the effect of this principle on the sp[illegible] the stars, or sometimes on sunlight reflected by a 45deg. [illegible] into the line of the earth's motion (which is not a possible [illegible] wholly failed. I take pleasure in remembering that this ef[illegible] clearly observed for the first time by the gentleman we [illegible] honour as our president; and that is by this very means t[illegible] latest sensational discovery in astronomy of the rapidly-re[illegible] twin star β-Aurigæ, by Prof. Pickering and the staff co[illegible] with the Draper Memorial was made.

The funds for the investigation that led to this result w[illegible] vided by Mrs. Draper, as a memorial to her late husband: [illegible] β-Aurigæ does not constitute a satisfactory memorial, I [illegible] loss to conceive the kind of tombstone which the relations o[illegible] of science would prefer.

The fourth event to which it behoves me to refer is the p[illegible] discovery of a physical method for colour photography. W[illegible] say practical I do not mean commercial, nor do I know tha[illegible] ever become applicable to the ordinary business of the [illegible] grapher. Whether it does or not, it is a sound achieve[illegible] physical means of a result which the chemical means hither[illegible] failed, some think necessarily failed, to produce. I say pr[illegible] because already it had been suggested as possible theore[illegible] and a step toward it, indeed very near it, had been [illegible] made.

The first suggestion of the method, so far as I know, w[illegible] by Lord Rayleigh in the course of a mathematical p[illegible] the reflection of light, and with reference to some re[illegible] Becquerel obtained on a totally different plan. He said [illegible] that if by normal reflection waves of light were convert[illegible] stationary waves, they could shake out silver in strata half [illegible] length apart, and that such strata would give selective re[illegible] and show iridescence.

The colour of certain crystals of chlorate of potash, desc[illegible] a precise manner by Sir George Stokes,† and also the co[illegible] opal and ancient glass, had been elaborately and co[illegible] explained by Lord Rayleigh on this theory of a periodic s[illegible] (the laminated structure in the case of chlorate of potash [illegible] caused by twinning‡); and he subsequently illustrated [illegible] sound and a series of muslin discs one behind the other on [illegible] lazy-tongs. Each membrane reflected an inappreciable [illegible] but successive equidistant membranes reinforced each [illegible] action, and the entire set reflected distinctly one definite [illegible] wave-length twice the distance between adjacent musl[illegible] also with any series of equidistant strata each very [illegible] reflecting. They should give selective reflection, [illegible] spectrum of their reflected beam should show a single [illegible] narrow band, corresponding to a wave-length twice the [illegible] of the strata apart.§

* Dr. Huggins has just pointed out to me a perfectly cle[illegible] ment to the above effect in Prof. Tait's little book on ligh[illegible]

† *Proc.* Roy. Soc., Feb., 1885.

‡ *Phil. Mag.*, Sept., 1888, pp. 256 and 241.

§ The footnote of Lord Rayleigh on p. 158, *Phil. Ma*[illegible] vol. xxiv., is brief and forcible enough to quote in fu[illegible] detailed experimental examination of the various cases in [illegible] laminated structure leads to a powerful but highly-selecte[illegible] tion would be of value. The most frequent examples are [illegible]

is more complicated, and has been less investigated, than either the liquid or the gaseous; a state in which time and past history play an important part.

Whichever of these long researches requires to be entered on, a national laboratory, with permanent traditions and a continuous life, is undoubtedly the only appropriate place. At such a place as Glasgow the exceptional magnitude of a present occupant may indeed inspire sufficient piety in a successor to secure the continuance of what has been there begun; but in most college laboratories, under conditions of migration, interregnum, and a new *regime*, continuity of investigation is hopeless.

I have, at any rate, said enough to indicate the kind of work for which the establishment of a well-furnished laboratory with fully-equipped staff is desirable, and I do not think that we as a nation shall be taking our proper share of the highest scientific work of the world until such an institution is started on its career.

There is only one evil which, so far as I can see, is to be feared from it. If ever it were allowed to impose on outside workers as a central authority from which infallible dicta were issued, it would be an evil so great that no amount of good work carried on by it could be pleaded as sufficient mitigation.

If ever by evil chance such an attitude were attempted, it must rest with the workers of the future to see that they permit no such shackles, for if they are not competent to be independent, and to contemn the voice of authority speaking as mere authority, if their only safeguard lies in the absence of necessity for struggle and effort, they cannot long hope to escape from the futility which surely awaits them in other directions.

I am thus led to take a wider range, and, leaving temporary and special considerations, to speak of a topic which is as yet beyond the pale of scientific orthodoxy, and which I might, more wisely, leave lying by the roadside. I will, however, take the risk of introducing a rather ill-favoured and disreputable-looking stranger to your consideration, in the belief—I might say, in the assured conviction—that he is not all scamp, and that his present condition is as much due to our long continued neglect as to any inherent incapacity for improvement in the subject.

I wish, however, strenuously to guard against its being supposed that this association, in its corporate capacity, lends its countenance to, or looks with any favour on, the outcast. What I have to say—and after all it will not be much—must rest on my own responsibility. I should be very sorry for any adventitious weight to attach to my observations on forbidden topics from the accident of their being delivered from this chair. At the same time I am distinctly one of the army of scientific workers; one of the many who have devoted their lives to the service of truth in general, so far as they are able to perceive it; and not only have I the right to express myself concerning matters on which I have worked, but I conceive it to be a duty, from which, if I shrank, I should shrink from no higher motive than simple cowardice. I therefore make no apology whatever for saying what I have to say, but I do hope that any quacks or professional exhibitors who would be able to make capital out of an utterance by a mouthpiece of a section of the British Association will be prevented from any attempt of the kind by this prelude and the assertion of merely personal responsibility. The objection at which I have now hinted is the only one that seems to me to have any just weight, and on all other counts I am willing to incur such amount of opprobrium as naturally attaches to those who enter on a region where the fires of controversy are not extinct, and in which it is quite impossible, as well as undesirable, for everyone to think alike.

It is but a platitude to say that our clear and conscious aim should always be truth, and that no lower or meaner standard should ever be allowed to obtrude itself before us. Our ancestors fought hard and suffered much for the privilege of free and open enquiry, for the right of conducting investigation untrammelled by prejudice and foregone conclusions, and they were ready to examine into any phenomenon which presented itself. This attitude of mind is perhaps necessarily less prominent now, when so much knowledge has been gained, and when the labours of many individuals may be rightly directed entirely to its systematisation and a study of its inner ramifications; but it would be a great pity if a too absorbed attention to what has already been acquired, and to the fringe of territory lying immediately adjacent thereto, were to end in our losing the power of raising our eyes and receiving evidence of a totally fresh kind, of perceiving the existence of regions into which the same processes of enquiry as had proved so fruitful might be extended, with results at present incalculable and perhaps wholly unexpected. I myself think that the ordinary processes of observation and experiment are establishing the existence of such a region—that, in fact, they have already established the truth of some phenomena not at present contemplated by science, and to which the orthodox man shuts his ears.

For instance, there is the question whether it has or has not been established by direct experiment that a method of communication exists between mind and mind irrespective of the ordinary channels of consciousness and the known organs of sense, and, if so, what is the process. It can hardly be through some unknown sense organ, but it may be by some direct physical influence on the ether, or it may be in some still more subtle manner. Of the process I as yet know nothing. For brevity it may be styled "thought-transference," though the name may turn out to be an unsuitable one after further investigation. F[illegible] investigation is just what is wanted. No one can [illegible] to accept his word for an entirely [illegible] fact, excep[illegible] ng a *prima facie* [illegible] for inves[illegible]

Bu[illegible] takı[illegible] nce of wh[illegible]

Whet[illegible] or a[illegible], I suppo[illegible]

the recognised scientific societies who would receive a [illegible] subject. There are individual scientific men who ha[illegible] gated these matters for themselves. There are othe[illegible] willing to receive evidence, who hold their minds op[illegible] judgment in suspense; but these are only individuals. [illegible] majority, I think I am right in saying, feel active ho[illegible] researches and a determined opposition to the recep[illegible] cussion of evidence. And they feel this confirmed [illegible] they call it, not after prolonged investigation —for the[illegible] be justified—but sometimes after no investigation at a[illegible] tricks at a public performance, or the artifices of some [illegible] and they decline to consider the matter further.

That individuals should take this line is, howeve[illegible] enough; they may be otherwise occupied and intere[illegible] body is by no means bound to investigate everythin[illegible] indeed, it is customary in most fields of knowledge fo[illegible] have kept aloof from a particular enquiry to defer in m[illegible] those who have conducted it, without feeling themse[illegible] upon to express an opinion. Some there are, no doub[illegible] sider that they have given sufficient time and atte[illegible] subject with only negative results. Their evidence is [illegible] important; but, plainly, negative evidence should be [illegible] bulk and weight before it can outweigh even a modera[illegible] of positive evidence. However, it is not of the action o[illegible] that I wish to speak: it is of the attitude to be a[illegible] scientific bodies in their corporate capacity; and fo[illegible] body of men of science, inheritors of the hard-won tr[illegible] free and fearless enquiry into the facts of nature untram[illegible] prejudice, for any such body to decline to receiv[illegible] laboriously attained and discreetly and inoffensively p[illegible] observers of accepted competency in other branches, [illegible] ever actually done and persisted in, a terrible throwing[illegible] their prerogative, and an imitation of the errors of [illegible] thought against which the struggle was at one time seve[illegible]

(*To be continued.*)

ADDRESS TO THE MECHANICAL SCIENCE S[ECTION] OF THE BRITISH ASSOCIATION.

BY T. FORSTER BROWN, M.INST.C.E., PRESIDENT OF THE S[ECTION].

I feel extremely diffident in assuming the president[illegible] Section G at the present meeting of the British Associati[illegible]

The addresses of my eminent predecessors have, year b[illegible] the best language, and in the most condensed form, g[illegible] progress of and indicated the direction in which furthe[illegible] ments in mechanical science may be looked for. In so la[illegible] as that of mechanical engineering my somewhat limited [illegible] will not admit of my following very closely in their foot[illegible] possibly, by tracing the modern practice of this branch [illegible] to mining operations in Great Britain, I may be able t[illegible] some points of interest to mechanical engineers.

Great progress has been made in mechanical science [illegible] British Association met in the Principality of Wales 11 y[illegible] and some of the results of that progress are exemplifi[illegible] locomotives, marine engineering, and in such works as th[illegible] Tunnel, the Forth and Tay Bridges, and the Manches[illegible] Canal, which is now in progress of construction.

In mining, the progress has been slow, and it is a re[illegible] fact that, with the exception of pumping, the machinery [illegible] connection with mining operations in Great Britain [illegible] regard to economy, advanced so rapidly as has been the c[illegible] manufactures and marine.

This is probably due, in metalliferous mining, to the [illegible] nature of the mineral deposits not affording any adequat[illegible] to adventurers that the increased cost of adopting [illegible] appliances will be reimbursed; whilst in coal mining, the [illegible] of fuel, the large proportion which manual labour bears to [illegible] cost of producing coal, and the necessity for produc[illegible] outputs with the simplest appliances, explain, in some [illegible] the reluctance with which high-pressure steam compoun[illegible] and other modes embracing the most modern and appro[illegible] of economising power, have been adopted.

Metalliferous mining, with the exception of the worki[illegible] ore, is not in a prosperous condition owing to causes to [illegible] unnecessary to refer; but in special localities, where th[illegible] of mineral are rich and profitable, progress has been m[illegible] a recent period by the adoption of more economical an[illegible] machinery.

For example, at the Tincroft Tin Mine, in Cornwall, a [illegible] winding plant has been erected by Messrs. Harvey, of [illegible] which the following are particulars: The high-pressu[illegible] is 17in. in diameter and steam-jacketed, and the lo[illegible] cylinder is 30in. in diameter, each having a stro[illegible] A condenser is worked by levers off the cross-he[illegible] low-pressure cylinder. The drum is 8ft. 6in. in [illegible] and of the plain cylindrical type. The engine [illegible] with steam reversing gear, and an auxiliary steam [illegible] admitting high-pressure steam to either end of lo[illegible] cylinder when required. The working pressure of steam [illegible] per square inch. This engine has proved so satisfactory [illegible] management of the mine has been induced to [illegible] horizontal condensing compound air-compressing engine [illegible] of their existing plant. This engine will have high[illegible] pressure cylinders of 15½in. and 27in. diameter respe[illegible] 48in. stroke, and the air cylinder is 22in. in diameter, [illegible] equal stroke, and is fitted with Trestrail's patent [illegible]

valves, and is arranged for a working pressure of 100lb. per inch.

the Greenside Lead Mines, near Ullswater, a waterfall of ds of 100 h.p. is now being utilised by means of a turbine to dynamos, the energy from which is transmitted for the ses of winding, pumping, and lighting; and, again, at the n Gold Mines, near Dolgelly, there is a modern example of ccessful utilisation of water power for compressed air, and iving 40 head of stamps. The water power for driving the obtained from the River Mawddach, and is brought on to a turbine, with a 68ft. head; this fall, with 650 cubic feet of , easily drives the mill, stone breakers, etc., and with 800 feet of water applied, if required, the water power can be to 100 h.p.

l, as an example of the very large amount of mechanical applied in exceptional circumstances to metalliferous mining tions, the Whicham Hæmatite Iron Mines, in South Cumber- may be named, where the quantity of water raised from a of 552ft. occasionally exceeds 4,800 gallons per minute, the inery employed consisting of –

stly, a Cornish beam condensing pumping engine, having a diameter cylinder by 11ft. stroke, with a 10ft. stroke in the s. The beam weighs 50 tons. There are attached to this e three pump rams, each 28in. in diameter, fixed at certain s in the shaft, the bottom ram being fixed 552ft. below the ce, from which level the whole of the water is pumped. The tity of water delivered per minute is 2,210 gallons. There is another Cornish beam condensing pumping engine, with a der of 110in. in diameter by 11ft. stroke, with a 9ft. stroke in pumps. This beams weighs 55½ tons. Attached to this engine hree 50in. diameter pump rams, forcing from the same level hat beforementioned a quantity of 2,295 gallons of water per ate. In November and December during heavy floods as much 680 gallons have been pumped from this mine per minute by e two engines.

he average consumption of coal by these engines is equal to at 4lb. per indicated horse-power.

here is another engine erected at this mine which is kept in rve in the event of anything happening to either of the two r engines which I have described viz., a tandem horizontal pound condensing pumping engine, having a 40in. high-sure and a 70in. low-pressure cylinder by 9ft. stroke. This ine is fitted with Davey's differential valve gearing. There is ched to this engine two 24in. diameter pump rams fixed at a t 372ft below the surface. These pumps are capable of dealing h 280 gallons of water with each stroke of the engine, and the imum speed is seven strokes per minute, which represents, refore, 1,960 gallons of water per minute. Provision is made h this engine to extend the pumps to a lower level when essary.

he weight of the pumps and pipes connected with these engines bout 250 tons.

n the raising of coal from our mines and placing it on board p in our docks there is a vast amount of machinery employed, ch of which is now of an obsolete type. Where, however, new nings have been made, or where in old mines it has been found essary to replace the old machinery by new, the question of ciency and at the same time economy in machinery has of late s received serious attention.

he consideration of the question of economy in the employment steam in coal-mining operations has resulted in boilers of the t modern construction being erected, working to pressures ying from 80lb. to 150lb. per square inch, as compared with sures varying from 40lb. to 50lb. per square inch in the old lers, whilst the various engines are now being constructed on most modern and improved principle.

ompressed air has for many years been used extensively in our l mines as a motive power. Electricity also has made rapid des in the same direction; and I have no doubt that, in con-ction with a better type of machinery for the compression and of air, will eventually become the principal agent in under-und mechanical operations.

lany large electrical installations have already been in use for a siderable period. Notably amongst the number I may mention t at Messrs. Locke and Co.'s St. John's Colliery, Normanton, ere both hauling on the endless-rope system and pumping are y largely adopted, and it has been proved that a useful effect al to 65 per cent. can be obtained. This high rate of efficiency ndoubtedly very satisfactory. I am, however, of opinion that re is still great room for improvement in electrical plant before ill be adopted in preference to other machinery now in general , especially in gaseous mines, and these improvements must brace a certain means of rendering sparking absolutely harmless ler all conditions, for it involves not only the question of the reased efficiency of one class of machinery over another, but the protection of human life.

here must also be devised a ready means of reversing the wer, so that the system of haulage known as the main and tail-e system can be applied with equal safety and readiness in any t, as compared with absolute safety in the use of compressed air.

n electrical hauling plant, to be worked on this system (which, m sure, will be watched with very great interest), is now erected one of the Plymouth collieries in this district by an eminent firm electricians as a trial and demonstration of what can be done in direction. This will comprise, when fully complete, a gene-ing plant at the top of the pit, and two electrically-driven ling engines underground, connected by a suitable cable carried n the shaft and along the roadway for some 1,200 yards.

he generating plant and one hauling engine are now erected, the other hauling engine will shortly be ready.

The generating plant consists of a 40-h.p. compound engine working at 110 revolutions per minute; this engine drives by belt a specially constructed dynamo, which is of a horizontal pattern, built on a wrought-iron girder bed-plate. It is compound wound, and capable of giving off 160 amperes with 500 volts pressure, running at 500 revolutions per minute.

The cable, which is 3,200 yards in length, is made of 37 strands of No. 14 high conductivity copper wire, highly insulated with vulcanised bitumen, double taped, and surrounded with two layers of jute yarn compounded between each, and is protected by a double sheath of No. 8 steel wire. It is of sufficient size to carry the necessary current, and in case of falls of roof it has been constructed so that it will stand a shearing strain of 10 tons per square inch.

The hauling engine consists of two drums, each fitted with a clutch and foot brake. The drum shaft is driven from a counter-shaft by spur gearing, and this countershaft is driven from the motor by six ropes 1in. in diameter.

The motor is a shunt wound machine, built to run at 600 revolutions per minute, and works with 80 amperes at 450 volts, and is able to take 160 amperes without harm at starting. The whole engine is mounted on a wrought-iron bed-frame. The motor will be reversed by a specially-designed switch, the efficiency of which has yet to be proved. The useful effect of this plant, when working at full power, is expected to be from 60 to 65 per cent.

Possibly the leather belting and ropes used for transmitting the power from the motor to the hauling drums or pipes might with advantage be replaced with something less liable to be damaged by the rough usage and other contingencies usually met with underground.

As I have previously mentioned, compressed air is another motive power very largely used in coal-mining, it being not only absolutely safe in gaseous atmospheres, but tends to reduce any danger which might exist from sudden outbursts of gas by assisting the ventilation. This may be considered as rather an expensive means of assisting ventilation; but it is very seldom that the air is used direct from the mains for this purpose. A very interesting paper was read at the Newcastle-upon-Tyne meeting of this association, in 1889, by Prof. Alex. B. W. Kennedy, on the experiments he had made in Paris upon the transmission of power by compressed air, in which he states that an indicated efficiency of 31 per cent. can be got from cold air, and 45 per cent. from air which has been heated after compression. It is very doubtful, however, if in any compressed-air installation used in coal-mining there is more than 30 per cent. of useful effect obtained; in many instances it is much less, as it is impossible in almost every case to heat the air after it has passed into the mine; and another source of loss is due to leakage, caused in a great measure by the occasional upheaval of the ground disturbing the pipes. It is thus obvious that compressed air is more costly than electricity; but up to the present time it is the only absolutely safe power which is capable of being conveyed long distances underground in gaseous mines.

A very large compressing plant has quite recently been erected in this district, and another will very shortly be installed; this latter will consist of two pairs of tandem compound steam engines, each pair having two high-pressure cylinders 22in. in diameter, and two low-pressure cylinders each 40in. in diameter, by 5ft. stroke. The air cylinders are 34in. in diameter, one being placed behind each low-pressure cylinder. Each high-pressure cylinder is provided with variable expansion valves, which can be adjusted whilst the engines are working. The independent condensing apparatus consists of a pair of engines having 10in. diameter cylinders, and 20in. diameter air pumps, by 2ft. 6in. stroke, and are so arranged that they can be worked together as a pair or as single engines and condensers.

The pressure of steam at the boilers will be 150lb. per square inch, so that a high degree of expansion may be obtained, and as the inlet and outlet valves of the air cylinders are of large area, and are perfectly free to act in sympathy with the pistons in the air cylinders, it is only reasonable to expect the highest degree of efficiency which can be obtained from steam power applied to compressing air. Each pair of air-compressing engines will be capable of developing at least 800 h.p., or a total of 1,600 i.h.p. in the installation.

No provision has been made in this plant for compounding the air cylinders or the motors; but it has been pointed out by Prof. Elliott, of the Cardiff University, in a very interesting and able paper read before the South Wales Institute of Engineers, that great economy will result in compounding the air and motors. Prof. Elliott estimates the extra efficiency, under certain conditions of high pressure, as upwards of 11 per cent. Further investigation in regard to defining the relative economy of using high and low pressed air for underground mining operations, and the relative cost of the plant adapted for the production and application of each, is required before it can be definitely decided that air of a pressure above four atmospheres, but with air cylinders and motors compounded, will result in real economy. It appears on the first blush as if we might look in the direction indicated to secure a material increase in the effective power obtainable from compressed air.

In some of our coalfields very hard seams or veins of coal are met with, and various kinds of machinery have been devised to assist the coal hewer in severing the coal from the solid strata, and electrical appliances have in this class of machinery been more or less successful. It appears to me, however, that there is a want of simplicity about the majority of the machines which have come under my notice, which will operate against their general adoption.

In the conveyance of coal underground, from the face of the workings where it is loaded into trams by the workmen to the

bottom of the shaft, several systems of haulage are adopted, either worked direct by steam power, compressed air, or electrical motors, the principal of which are known as the endless-rope, main-and-tail-rope, and main-rope systems. The two former systems are used where the ground is either level or undulating, and where power has to be applied to haul the trams or tubs in both directions, and the latter system is generally used where there is a gradient in one direction, sufficient to allow the trams or tubs to run by gravitation, and haul the rope after them. The cost of the conveyance of coal underground is a very considerable item in South Wales, probably amounting to £600,000 or £700,000 per annum, and consequently has caused great attention to be given to the subject. It has been found that the endless-rope system, where it can be conveniently applied, is the cheapest. This system, however, necessitates the laying and maintaining of either a double line of rails, or frequent passing points or loops; and as the nature of the strata does not always admit of the roads being made and maintained wide enough for this to be done, the main-and-tail system, which requires a single line only, has in that event to be adopted. The distance to which some of these haulage systems extend is very great (in some cases exceeding three miles); and, having regard to the large quantities which have to be conveyed by mechanical haulage in single collieries—in many instances 1,000 to 1,500 tons of coal in 10 hours—very good and powerful machinery is required, and it is not unusual to have engines of 600 i.h.p. placed underground for this purpose. In other cases where the coal is brought from several districts to the bottom of the shafts, smaller engines are used. For endless-rope haulage, the speed at which the trams or tubs travel is from two to six miles per hour, as against from 10 to 20 miles per hour by the main-and-tail system; thus there is much greater wear and tear in the latter than in the former. The type of engine usually adopted for this work varies considerably according to circumstances, and the ideas of the engineer by whom the work is planned. They are, however, invariably horizontal, and fitted with a second motion shaft, on which the hauling drums are arranged. There is still a large number of horses employed underground, at very great cost, principally to collect the trams from the colliers and convey them to the station, from which point the engine hauls them, and it is to this class of haulage that I would particularly direct the attention of mechanical engineers. What is required is an absolutely safe and simple means of light haulage, made as portable as possible, so that it can be readily moved from one position to another, as circumstances may require, and arranged so as to replace the horses.

Thus, the coal is brought to the bottom of the shaft, and thence up the shaft by means of the winding engine. This class of engine has of late years been very materially improved. Instead of the low-pressure vertical beam condensing engine, which was so commonly in use many years ago, and types of which are still in existence, we have now the high-pressure compound condensing engine, working with a boiler pressure varying from 80lb. to 150lb. per square inch. Some of our winding engines are very powerful, and run at very high velocities. This will be the more readily understood from the fact that at some pits the carriages on which the coal is raised in the shaft attain a speed equal to from 40 to 45 miles per hour, and the dead load lifted is as great as 20 tons each lift. A few of the leading sizes of a large pair of winding engines now in use at one of the collieries in this district may be mentioned. The engines are vertical, with inverted cylinders of 54in. in diameter, and admit of a 7ft. stroke. The cylinders are steam-jacketed, and the valves double beat, placed in pairs in nozzle-boxes fixed to the port branches at the top and bottom of each cylinder. The valves are worked by the ordinary rocking lifters, to which is added, for the steam valves, the simple triple-expansion gear first introduced by Mr. Barclay, of Kilmarnock. The cylinders are supported by double A frames of cast iron fixed to heavy cast-iron bed-plates, to which also is attached the main shaft plummer blocks. The winding-drum is of the conical type, graduating from 16ft. to 32ft., and is made of steel plates and ribs and cast-iron centres. The total weight of the drum, drum shaft, and the engine cranks, and one rope, exceeds 100 tons. The engine is fitted with a powerful steam brake, and also a self-acting reversing gear, which reversing gear also applies the steam brake, in case of any neglect on the part of the engine man. There is also being built for a colliery in this coalfield a large pair of compound condensing winding engines by Messrs. Fowler, of Leeds, which will embrace all the latest improvements. They will consist of a pair of horizontal compound winding engines fitted with condensers; the high-pressure cylinder, being 32in. in diameter by 5ft. stroke, will actuate one crank, whilst the low-pressure cylinder, 48in. in diameter by 5ft. stroke, will actuate the other crank. Both cylinders are fitted with Cornish valves, and on the high-pressure cylinder there is fitted automatic variable expansion, worked by a governor, and the initial pressure of steam will be 150lb. per square inch. This engine will be fitted with a plain cylindrical drum, 18ft. in diameter, and a balance-rope will be attached to the underside of the carriages, so that everything will be in perfect balance.

Between the high and low pressure cylinders is a receiver, on which is fixed a valve arrangement by which the steam can be expanded out of the receiver, ... live steam can be admitted into it. This arrangement greatl... ...s the ease of starting the engines.

Ot... ...l with what might be termed an auxili... by ... ...al is lowered in boxes into the ship's

ping first of all placed on a cradle, which is raised by lic rams to the necessary height, when it is tipped to such le as to cause the coal to run out of the truck through a extending over the ship's hatchway, into what is termed i breakage box. The box being filled is then lowered into ip's hold, but its use is discontinued as soon as sufficient ty of coal has been loaded to form a cone sufficiently large event further breakage. The anti-breakage box is then out of the way, and the coal allowed to slide from the shoot he cone and into the hold, where it is trimmed into position. marising the position of mechanical science as applied to al-mining industry in this country, it may be observed that s a general awakening to the necessity of adopting, in the and deeper mines, more economical appliances.

s true that it would be impracticable, and probably unwise, r much of the existing machinery, but, by the adoption of st-known types of electrical plant, and air compression in w and deep mines, the consumption of coal per horse-power be reduced, and the extra expense, due to natural causes, of cing minerals from greater depths would be substantially ed. The consumption of coal at the collieries in Great n alone probably exceeds 10,000,000 tons per annum, and the mption per horse-power is probably not less than 6lb. of coal, is not unreasonable to assume that, by the adoption of more nt machinery than is at present in general use, at least one- f the coal consumed could be saved. There is, therefore, in ines of Great Britain alone a wide and lucrative field for the tive ingenuity of mechanical engineers in economising fuel, specially in the successful application of new methods for g with underground haulage, in the inner workings of our ries, more especially in South Wales, where the number of s still employed is very large.

aving the subject of mining, I may observe that considerable ess has within recent years been made in the mechanical ances intended to replace horses on our public tram lines. team engine now in use in some of our towns has its draw- as well as its good qualities, as also has the endless-rope uge, and in the case of the latter system, anxiety must be when the ropes show signs of wear. The electrically-driven s appear to work well. I have not, however, seen any shed data bearing on the relative cost per mile of these ral systems, and this information, when obtained, will be of est.

the present time, I understand, exhaustive trials are being with an ammonia gas engine, which it is anticipated will both more economical and efficient than horses for tram s. The gas is said to be produced from the pure ammonia, ined by distillation from commercial ammonia, and is given off pressure varying from 100lb. to 150lb. per square inch. This onia is used in specially-constructed engines, and is then usted in a tank containing water, which brings it back into riginal form of commercial ammonia, ready for redistillation, it is stated, with a comparatively small loss.

uch attention in modern times has been given to the relative es of the numerous new explosives which have been introduced blasting in mines and for other purposes. Sir Frederick Abel e greatest authority upon this subject. As applied to mining, ous experiments have from time to time been made for the pose of testing how far it would be safe to employ these osives in the atmosphere of a coal mine without the risk of ing an explosion of fire-damp. A number of these are mainly posed of compounds of nitro-glycerine with aluminous earth. whilst the experiments have indicated that, with rare excep- s, they are practically flameless, it is undoubted that one which ld be absolutely so, and which could be used with safety in mines, has yet to be produced.

he adoption in our gaseous mines of a flameless explosive, a contained electric lamp of moderate weight which will burn out attention for 12 hours, and the general application of r to moisten the dust, are all more or less questions in which mechanical engineer is interested, and, when adopted, will ably have the effect of putting an end to the disastrous losions accompanied by loss of life which occurs at intervals in fiery collieries, and I trust that the deliberations of this ion may result in the practical adoption of steps to secure this rable object.

conclusion, as an inhabitant of Cardiff, I may be permitted ongratulate this port on this the first visit of the British ociation. Its rising importance is becoming generally recog- d, and since the last visit of the British Association to the cipality material progress has been made. Lord Bute has tructed a large dock of 33 acres at Cardiff, and a still larger of nearly 70 acres has been constructed at Barry within the of Cardiff. The tonnage of shipping cleared at the port has eased during the past 11 years 91 per cent. Various new stries have been established here, notably, the manufacture matite iron for steel making, on a large scale, by the Dowlais Company; and the exportation of coal has increased from 2,349 tons in 1880 to 12,250,652 tons in 1890, or 109 per cent. Swansea the manufacture of tin-plates, which is one of the ing industries of the western part of this country, has eased from 25,343 tons to 229,791 tons in 1890; and the trade he neighbouring port of Newport has also materially developed, howing a rapid progressive development of the large resources outh Wales.

trust that only a short interval will elapse before we are oured with another visit of the British Association, and that it be the good fortune of the president who may have the our of occupying this chair on that occasion to chronicle lar progress.

GREAT YARMOUTH.

THE BOROUGH SURVEYOR'S REPORT.

The following report to the Yarmouth Town Council upon the electric lighting of the town by the borough surveyor, was submitted by the Electric Lighting Committee at the last monthly meeting:

"Gentlemen,—In accordance with your instructions I submit the following report on the above subject. Since my last report in October, 1889, much has been done to develop this industry, and manufacturers of electric lighting plant have been extremely busy, but few of the towns obtaining a provisional order at the same time as yourselves are much further advanced than you are in carrying out the work for which they have obtained the powers. I will, however, ascertain if you wish it at your next meeting what each has done. I have taken this subject up as a special matter for study, that I might be prepared should I be called upon by you either to design your installation or ultimately to superintend the working of it when the same should be completed, and the information now before me is so great that the difficulties of framing this report consists in condensing the information within the limits which you will have patience to consider. Cost.—A great deal has been written on the subject of the comparative cost of gas and electricity, and the figures which I gave you, and the statements made in my last report referred to above, have been fully borne out—viz., that, light for light, the cost of electricity was about equal to gas at 3s. 3d. per 1,000 cubic feet, but I must remind you that the public have been led to expect such a brilliant light from electricity that an electric lamp of only the same power as an ordinary gas lamp would not be considered satisfactory. Recently, at the annual meeting of the Incorporated Association of Municipal and Sanitary Engineers I had the privilege of listening to an address on the comparative cost of electricity and gas by W. H. Preece, Esq., F.R.S., electrical adviser to the Post Office authorities, and he, after describing the quantities of electricity and gas obtainable from the same quantity of coal, and other technical matters, stated that 'the average amount, taking the return from the nine chief towns of this country, paid per gas-burner per annum is 9s., the average price of gas being 3s. per 1,000 cubic feet; the average amount per lamp of the 200,000 electric lamps burning in London is 10s., the average price being 7½d. per Board of Trade unit.' In Manchester Mr. Preece stated that the average price paid per gas lamp was 7s. 6d., and that electricity would cost 8s. 4d. That the post office at Newcastle was lighted by electricity supplied at 4½d. per unit, with a discount of 20 per cent., which made the cost of electric lighting there very nearly approach that of gas (gas being 2s. per 1,000 cubic feet, with a discount of 10 per cent.). He further stated that at Bolton, Messrs. Horrocks, Crewdson, and Co. had used electric light for six years, the cost per electric lamp being 4s. 0¼d. against 5s. 6¾d. per gas burner. Among the advantages of electricity over gas, Mr. Preece called attention to cleanliness, health, security from fire, and the small space which electric lighting works occupied. These statements and all the information I have collected proves that electricity now costs about the same, light for light, as is paid for gas in the town portion of the borough, and the ease and economy with which you are able to obtain the necessary capital to carry out the works should make the supply of electricity a fairly remunerative one to you, should a sufficient number of persons be prepared to lay it in, but I would not advise you to undertake a less installation than 4,000 lights, you yourselves requiring about 1,000 lights for Town Hall, Fish Wharf, Free Library, and Police Station, independently of any public lighting of streets you may undertake. Systems.—A great analogy exists between the distribution of electricity and the supply of water and gas, but there are three ways in which electricity may be applied to central lighting of towns—namely, direct supply, transformer system, and accumulator system. (The report went on to say that electricians are divided in opinion to a very considerable extent on which of the systems are the best for central station lighting.) I am of opinion that either the second or third system could be applied in this town. The second system appears to be the one more favourably received, it being a comparatively simple mode of distributing electricity, but in case of breakdown of machinery the supply would fail, and the machinery must be kept running if only a small number of lights are required. As a rule consumers would not, however, object to the supply being off from midnight until lighting time next day. The advantages of the third system are that the electricity can be stored so that breakdowns in the machinery would make no difference in the lights and electricity can be generated during the day for night use, but the storage batteries would require careful attention. Lighting of Public Streets.—If this is done a portion of the town, such as streets, squares, etc., would have to be lighted with arc lamps, while the narrow streets and rows would be lighted with incandescent lamps. Recommendations.—I would recommend: 1. That information be obtained as to the number of persons in the town willing to guarantee taking a supply from you for a not less term than two years, and what their requirements would be; and that an advertisement be issued in local papers in a similar form to that given at the end of this report. 2. That I obtain the latest information in a tabulated form from each town in which the electric lighting has been adopted, either by the Town Council or by a private company; also from towns which have obtained provisional orders, as to what has been done, the system at

work, the results of its working, and general information likely to be of use to you in determining the best course to adopt. 3. That the borough accountant obtain information as to the financial results which have attended the working of the electric light either by private companies or corporations, and report thereon. 4. That a small committee shall be empowered to visit some six or eight towns and inspect the various systems at work with a view to considering the questions of the best system for you to adopt, and the practicability and desirability of lighting the roads and streets with the electric light.—I am, gentlemen, yours obediently, J. W. COCKRILL, A.R.I.B.A., A.M.I.C.E., borough surveyor."

On the motion of **Mr. Burton**, seconded by **Mr. Fenner**, it was resolved to recommend the Council to adopt the borough surveyor's four recommendations, and to appoint the following sub-committee to carry out the borough surveyor's fourth recommendation: the chairman, and Messrs. Arnott, Harvey George, and Martins.

Mr. Harvey-George moved the adoption of the report, and

Mr. F. D. Palmer seconded, observing that he would withdraw the motion in his name on the agenda paper, to the effect that it be an instruction to the special committee to proceed with the electric lighting order forthwith, as the committee had taken the course he proposed.

The report was adopted, and, on the motion of **Mr. Harvey-George**, Mr. Palmer was added to the committee.

NEW COMPANIES REGISTERED.

British Electro-Chemical Agency, Limited.—Registered by Bonner, Wright, and Co., Ingram House, 165, Fenchurch-street, E.C., with a capital of £75,000 in £10 shares. Object: to adopt and carry into effect an agreement expressed to be made between the Electric Construction Corporation, Limited, of the one part and this Company of the other part, and to carry on in all its branches the business of electricians and electrical engineers. The first subscribers are:

	Shares.
J. Ebbsmith, Worcester House, Walbrook	1
J. Pender, Thorne Hall, Rugby	1
J. B. Verity, 31, King-street, Covent-garden, W.C.	1
H. C. Mance, Kt., Manova, Newnham-road, Bedford	1
T. Parker, Newbridge, Wolverhampton	1
J. Balfour, Savoy-hill House, W.C.	1
J. S. Balfour, Whitehall-court, S.W.	1

There shall not be less than three nor more than seven Directors. The first shall be Messrs. J. Ebbsmith, J. B. Verity, and J. Balfour. Qualification, £250. Remuneration, £1,000 per annum, with an additional sum of 10 per cent. on the net profits of the Company. Ordinary Directors: When not more than 5 per cent. dividend shall be paid, £150 each per annum; when not more than 10 per cent. dividend, £300 each; and £600 each after payment of 10 per cent. dividend; such remuneration to be divided as the Directors themselves shall determine.

The Electric Installation and Maintenance Company, for the supply of electricity to the Crystal Palace, Sydenham, and district, is a new undertaking with a capital of £100,000, divided into 10,000 £10 shares, of which 626 shares have been already allotted, the present issue being £60,000 in 6,000 shares, 1,124 of which will be allotted as fully paid-up to Messrs. J. E. H. Gordon and Co., Limited, the contractors, in part payment for the works. The Company has obtained a provisional order from the Board of Trade, which has been duly confirmed by Act of Parliament. The objects of the Company will primarily be to supply, by means of electric motors, the power required by exhibitors at the forthcoming Electrical Exhibition at the Crystal Palace in the ensuing winter, and, further, to supply electricity for light and power purposes to the Crystal Palace and district surrounding it.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts for last week amounted to £4,261.

City and South London Railway.—The receipts for the week ending 15th inst. were £653, against £821 for the week ending 8th inst.

Western and Brazilian Telegraph Company.—The receipts for the week ending August 14, after deducting 17 per cent. of the gross receipts payable to the London-Platino Brazilian Telegraph Company, were £2,835.

PROVISIONAL PATENTS, 1891.

AUGUST 10.

13503. **Improvements in electric machines and apparatuses for differential phase alternating currents.** Michael von Dolivo-Dobrowolsky and the Company Allgemeine Elektricitäts Gesellschaft, 47, Lincoln's-inn-fields, London. (Complete specification.)

13465. **Improvements in electrical automatic stopping apparatus for weft pile cutting machines.** William Oscar Drey, 64, Barton-arcade, Manchester.

13492 **A method and apparatus for electrical propelling vehicles.** Francis Edward Elmore, 28, Southampton-buildings, London.

AUGUST 11.

13528. **Improved electric time-registering apparatus for cabs and the like.** Arthur Douglas, 13, Southampton King's Cross, London.

13529 **Improvements in methods and apparatus for ... and utilising electric light.** James Alfred ... Rockley-road, Shepherd's Bush, London.

13553. **Improvements in electrically heated ovens** Mitchell, 115, Cannon-street, London. (Complete specification.)

13554. **Improvements in electric steam generators** Mitchell, 115, Cannon-street, London. (Complete specification.)

13558. **Improvements in unipolar continuous current ... or dynamo-electric machines.** Jules Cauderay, 28, Southampton-buildings, London.

AUGUST 12.

13589. **Improvements in electric conductors.** Georg Heyl, 38, Alexander-street, Berlin, C., Germany

13627. **An improved alternating electric current** William Blanch Brain and Arthur James A... Lincoln's-inn-fields, London. (Complete specification.)

AUGUST 13.

13628. **Improvements in dynamos for generating ...** Wilson Hartnell, Benson's-building, Park-row, Leeds.

AUGUST 14.

13692. **Improvements in electric arc lamps.** Arthur Mitchel-Jones, 70, Market-street, Manchester.

13705. **An improved coupling for connecting electric ...** Alexander Shiels, 70, Wellington-street, Glasgow.

13714. **Improvements in and relating to apparatus for measuring electric currents.** Herbert Woodville ... York-mansions, Earl's Court, London.

13753. **Improvements in telegraphic call-boxes.** ... Melville Clark, 53, Chancery-lane, London (Jo... Noyes, United States.) (Complete specification.)

AUGUST 15.

13802. **Improved electric current generator for ... multiple phase alternating currents.** Johannes ... 28, Southampton-buildings, London.

13809 **New or improved machinery for covering ... ductors with leather.** George Hughes, 38, Cha... London (Emile Edward Legrand, France.) (Complete specification.)

SPECIFICATIONS PUBLISHED.

NOTES.

Prague.—The electric railway to the Baumgarten commenced running on July 18.

Electric Cars.—It is stated that there are now over 800 electric cars running regularly in the city of Boston (U.S.).

Chicago is to have an underground railway, and a company with a capital of 10 million dollars has been formed to carry out the work.

Electric Railways.—A practical treatise on "Electric Railways and their Working," is in preparation by Dr. Louis Bell and Mr. O. T. Crosby.

Whitechapel. — The Whitechapel Vestry, having determined to obtain their own provisional order, have instructed their clerk to take the necessary proceedings.

Personal.—Mr. J. T. Niblett, recently with Mr. Pitkin, has joined the Mining and General Lamp Company (who own the FitzGerald lithanode patents) as general manager.

British Association.—The new president-elect of the British Association is to be Sir Archibald Geikie. The meeting is to be held in Edinburgh, commencing 3rd August.

Early Telegraph Companies.—The well-known financial paper the *Oracle* is publishing a series of very interesting articles on the early financial and commercial history of the Atlantic telegraph companies.

Appointment.—Mr. T. Smith, five years engaged at Messrs. Immisch's works at Kentish Town, has been appointed secretary to the General Electric Traction Company, which position was rendered vacant by the sad death of Mr. Mackenzie.

Lowestoft.—The town clerk of Lowestoft has been instructed to report to the Town Council as to the cost of obtaining a provisional order under the Electric Lighting Acts; and also as to the charges made for electric current in other towns.

Maidstone.—The Maidstone Local Board are giving their earnest attention to the subject of the electric lighting of the town, and have appointed the Mayor, ex-Mayor, and Alderman Long as a committee to make enquiries as to the proposed provisional order.

Spain.—An electric central station is shortly to be erected at the mill belonging to one of the large capitalists in Aranjuez. A water power of 180 h.p. will be applied to light 31 arc lamps and 600 incandescents. Three Siemens four-pole dynamos are to be used.

City Lighting.—The Board of Trade have given their final consent to the transfer to the City of London Electric Lighting Company, Limited, the provisional orders granted to the Brush Electric Engineering Company, Limited, and the Laing, Wharton, and Down Construction Syndicate, Limited.

Edinburgh.—On Tuesday, at a meeting of the Edinburgh Town Council, a representation was made by the town clerk, submitting the Edinburgh Electric Lighting Order, and craving a remit to the Lord Provost's Committee to consider and report what steps should be taken under the order.

Telephone Wire Struck by Lightning.—In the storm passing over the City on August 19 the telephone wire at 56, Paternoster-row was struck by lightning, which set the bell ringing. The flash was very vivid, and the bell had ceased before the peal of thunder was heard. The time was about 1.43.

Edinburgh.—At Edinburgh Town Council, on Tuesday, a representation by the town clerk, submitting the Edinburgh Electric Lighting Order, was remitted to the Lord Provost's Committee to consider and report what steps should be taken under the order to institute the commencement of electric lighting.

Hissing of the Arc.—In order to suppress the disagreeable noise in the arc, an inventor of the name of Allison has devised the plan of mixing an alkali silicate with the carbon. The evaporation of this as the arc burns forms a conducting vapour which is stated to overcome the inconveniences of hissing.

Electric Motor Outfit.—We notice in an American paper a cut of an electric motor and battery mounted on one stand. Such a thing as this is at once a novelty and useful piece of apparatus that is sure to find favour, and would be worthy of the attention of manufacturing electricians for small sizes of motors.

New Buildings.—Nunwick Hall, near Penrith, is about to be reconstructed for Mr. R. Heywood Thompson, the architect being Mr. Charles J. Ferguson, F.S.A., Carlisle. This should be a favourable time for introducing the "new illuminant." The same with the Armagh Asylum, which is to be added to. Address, Secretary, Board of Control, Dublin.

Bilston.—At the last meeting of the Bilston Town Council, the clerk (Mr. J. D. Wassell) was directed to advertise for tenders for lighting the Market Hall by electricity; also to ascertain from the Bilston Gas Company what sum they would pay the Commissioners for the privilege of lighting the hall, the company to provide all gas fittings.

"Punch" on Electric Lighting.—*Punch* has a vigorous cartoon this week showing a British householder contemplating the imp "Electricity" seated on an indescribable heap of picks, stones, and cables, and holding up his lamp. ELECTRIC LIGHT: "What, won't you let me in—a dear little chap like me?" HOUSEHOLDER: "Ah! You're a little too dear for me—at present."

Utilisation of Water Power.—A company has been formed at Solothurn, with a capital of 800,000f., to construct a canal between the Rivers Emme and Aar: the fall of water so made will be used to drive electric machinery. Two companies have been formed in the Jura for the utilisation of the power of the waterfall "Saut du Doubs" for the electric transmission of power.

Electric Miner's Lamp.—We are glad to learn that the prospect of work in electric miners' lamps is distinctly bright. Several of the larger collieries in the North of England are in negotiation for the extensive introduction of a storage battery lamp, and one colliery owner—subject to a test which the lamps are well calculated to withstand—is understood to have given an order for 600 of these electric miners' lamps.

Gas Engine Storage Cars.—The curious combination of gas engine, dynamo, motor, and storage batteries, all placed on a car, advocated by Mr. W. H. Palton, is stated to have been tried at Pullman "with much success." It seems an absurdity to engineering minds. There is one theoretical advantage, however, that the kinetic or potential energy of the car going down hill can be recovered and stored in the accumulators.

Liverpool Electric Railway.—The electric power for the Liverpool Overhead Electric Railway is, we understand, to be obtained from motors on each car, and not from an electric locomotive. The reason for this is the greater economy of traction, there being plenty of room in the overhead railway for the fitting of motors under the

carriages, an arrangement which could not be carried out in the restricted space in the tunnel of the South London line.

Electric Pinnaces.—We are pleased to learn from the General Electric Traction Company that they have received a third order for an electric pinnace from the Russian Government. The field for these electric pinnaces is very extensive, and it is understood that it is intended to fit several ironclads which have already electric light machinery on board entirely with these electric boats. Their use for the large Atlantic liners is also under contemplation.

Mont Blanc Observatory.—M. Imfeld, a Swiss engineer, has been engaged to examine the nature of the summit of Mont Blanc for the construction of M. Jansen's proposed observatory. Tunnels through the ice are being made at a point where it is thought that the ice is not over 40ft. thick. The conditions may be imagined from the fact that, in spite of the coke stoves, the temperature never rises above zero; the ink freezes, and water boils at 83deg. C., so that they cannot properly cook their meals.

The Barmen-Elberfeld Elevated Electric Railway.—It is stated that the difficulties in the way of giving a practical outcome to the projected elevated electric railway from Barmen to Elberfeld appear to have been overcome, as Messrs. Siemens and Halske, of Berlin, have now received instructions to proceed with the construction of the line. The railway will start from Barmen parallel with the River Wupper, which, near Elberfeld, will be spanned by a massive wrought-iron bridge to carry the railway.

New Insulation.—A new insulating material is manufactured by M. E. Legrand, composed of leather cuttings reduced to an impalpable powder, afterwards agglomerated by a special process under considerable pressure. The leather thus treated is no longer spongy, and is absolutely impermeable, having an insulation resistance, according to the *Bulletin International*, of about 1,000 megohms. It is incombustible, and stands the great currents that can be carried by the wires which it covers without melting or burning.

Deep Mining.—It is proposed at Wheeling, Virginia, to bore a hole direct into the earth for 20 miles or so, and 10ft. a day is now being constantly achieved. It is imagined that rich metal will be struck at some point lower down than usual, perhaps melted metals—copper, iron, or even gold and platinum—when the ore would spout up of its own accord without expense of mining. Fear is expressed that they may cause a miniature volcano, but it is more likely that they will strike water or oil before great depth is attained.

Electric Walking-Stick.—The ingenious M. Trouvé has again distinguished himself by the construction of an electric walking-stick, of which the knob consists of a small electric lamp in thick glass bulb, and the battery being two cells of a peculiar shape down the cane itself. The lamp gives sufficient light to read a newspaper in a train, or to light one'self upstairs at night. The genus "masher" will now have a chance to learn something about electrical science, and at the same time greatly amuse, interest, and astonish their friends.

Weymersch Battery.—During the past few months the Weymersch Electric Battery Synd[illegible], of 2, Victoria-mansions, Westminster, have made [illegible] improvement in the desig[illegible] [illegible]ir battery a[illegible] [illegible]d of its application to v[illegible] [illegible]al purpos[illegible] [illegible]pose giving an exhib[illegible] [illegible]ilities of [illegible] [illegible]ay (Friday) and o[illegible] [illegible]mber, [illegible]

may be seen charging accumulators, running a [illegible] Blackman fan, and working a Merryweather pu[illegible] 12 gallons a minute capacity.

Oil v. Electricity at Helston.—The Town C[illegible] of Helston last week appointed a committee to "t[illegible] necessary steps forthwith to invite tenders for the li[illegible] of the town with oil lamps in an efficient manner, [illegible] necessary, on account of urgency, to enter into nec[illegible] contracts for carrying out the lighting, avoiding, if poss[illegible] view of electricity in future), the purchase of any oil la[illegible] The committee were also allowed £10 for the purp[illegible] consulting an electrical engineer as to the probable [illegible] lighting the streets by electricity.

Cost of Electric Lighting Acts.—We note th[illegible] the last meeting of the Edinburgh Town Council, o[illegible] representation of the city chamberlain, the sum [illegible] £272. 13s. 3d., the cost of the promotion of the Edin[illegible] Corporation Electric Lighting Order, 1891, was transf[illegible] from the general police purposes account to the sp[illegible] account opened in the municipal department for adv[illegible] of expenses in connection with the promotion of the [illegible] The cost of obtaining a provisional order is often p[illegible] from £300 to £400. It will be seen from the above [illegible] the cost to the Edinburgh Corporation has been less [illegible] the former figure.

Deptford Station.—The statement recently is[illegible] that Mr. Ferranti had left the London Electric Compa[illegible] and gone abroad, resolves itself into the fact that [illegible] Deptford station now being completed for 100,000 lam[illegible] of which only 30,000 are yet taken up, and the need [illegible] economy pressing, the engagement of Mr. Ferranti as c[illegible] engineer to the corporation (which was coincident with [illegible] post as contractor) has in due course come to an end. [illegible] Ferranti is now devoting his whole energies to the devel[illegible] ment of his business at Charterhouse-square, which [illegible] naturally received only a portion of his attention duri[illegible] the great work at Deptford.

Substitute for Platinum.—It was recently announ[illegible] that Captain Walters, of Vienna, had invented a substitute [illegible] platinum for incandescent lamp manufactures. The al[illegible] seems to consist of tin 95 parts and copper five parts by weig[illegible] but other ingredients may be employed. It may be mi[illegible] with half to 1 per cent. of lead or zinc. The alloy adhe[illegible] strongly to glass surfaces, and is of the same coeffici[illegible] expansion as glass—a property hitherto only possessed [illegible] platinum, which is of course the cause of the use of [illegible] otherwise far too precious metal. The new alloy melts [illegible] 360deg. C., and if its promise be carried out should be [illegible] the utmost utility in electric lamp manufacture.

Course of Reading.—Dr. Louis Bell, in the *Electri[illegible] World*, has a chatty and useful article on a "Course [illegible] Electrical Reading." Whilst giving the names of some [illegible] the most useful books, he gives also much practical advi[illegible] "There is no royal road," he says, "to electrical knowledg[illegible] and he who seeks it is bound for continued and exasperati[illegible] disappointments. The natural tendency is to begin readi[illegible] special works before the general ones have been master[illegible] and the result of this, too often, is a sort of half-bak[illegible] electrician, neither capable of avoiding difficulties n[illegible] what is more important, of extricating himself if he [illegible] the misfortune to run foul of them."

British Association Grants.—The British Assoc[illegible] tion have adopted the following money grants, amo[illegible] others, to be appropriated to scientific purposes: Electri[illegible] standards (partly renewed), £27; meteorological observ[illegible] [illegible] on Ben Nevis, £50; photographs of meteorologic[illegible] [illegible]ena, £15; Pellian equation tables (partly renewe[illegible] £[illegible] of mathematical functions, £15; electroly[illegible]

£5 ; discharge of electricity from points, £50 ; seismological phenomena of Japan, £10 ; analysis of iron and steel (renewed), £8. 16s. ; formation of haloids from pure materials (partly renewed), £25. 5s. ; properties of solutions, £10 ; action of light upon dyed colours (partly renewed), £10.

Cork.—Says the *Gas World*: "From what the chairman of the Cork Gas Consumers' Company said to the shareholders at the half yearly meeting last week it is apparent that the directors of the company mean business by their proposal to acquire powers to supply the electric light. We hope they will persevere with the scheme, and so give the gas world generally an opportunity of judging what the prospects are of a gas company being able profitably to supply the electric light. It will be observed that the idea of the directors is to use gas engines for the generation of the electric current. They are fortunate in having a secretary in Mr. Denny Lane who has made a thorough study of both gas engines and the electric light."

Manchester.—The arrangements for supplying the public with the electric light are being rapidly pushed forward by the Electric Lighting Committee of the Manchester Corporation This committee had a meeting last week, and decided to make certain recommendations to the Gas Committee with reference to the details of the scheme. If the Gas Committee approve the recommendations, then the sanction of the Council will have to be obtained. They recommend, in the first place, that an engineer be appointed to prepare plans and specifications for carrying out the work. The committee do not as yet intend to interfere at all with the existing plan of street lighting; and the electric supply will be for houses, shops, and public buildings generally.

Electrical Accessories.—A company was formed a year or so ago under the name of the Electrical Accessories Company, in connection with Messrs. Drake and Gorham, and has been carried on from the same office. A great many useful and ingenious fittings were designed and manufactured, and a considerable measure of success has been attained, but the definite connection of a manufacturing with a contracting company rather militated against wider extension, and we now learn that the interest of Messrs. Drake and Gorham in the company has now been transferred, with all patterns, models, and patent rights, to the company, which is now entirely distinct. The Electrical Accessories Company will carry on business under the same name, and will shortly remove to another address.

Continuous-Current Transmission at Frankfort.—Besides the alternate-current transmission at Frankfort, the commencement of which we announce elsewhere, an installation of considerable importance has been almost at the same time started from Offenbach to Frankfort by continuous-current transmission. This has been carried out by the Lahmeyer Company, of Frankfort, and consists in the transmission of 100 h p. a distance of six miles. The current is a continuous one from a drum armature compound-wound dynamo of 2,000 volts, transformed in a secondary dynamo at the exhibition to 70 volts for supplying electric light and motors. The Lahmeyer system of direct-current transformers is patented. The same firm, as already mentioned, exhibits the Haselwander rotary-current motor, besides a distribution of power on a low-tension circuit.

Wynward Park.—A large installation has just been completed by Messrs. Drake and Gorham for the Marquis of Londonderry, comprising upwards of 1,000 lights of different candle-powers. The plant consists of two Davey-Paxman Lancashire boilers, which provide steam for two horizontal compound engines driving two 40-unit dynamos. A smaller Robey engine is also fixed to drive a 15-unit machine, so that a small current may be generated economically. This method of supplying a small plant as an auxiliary to the larger engines has been largely adopted by Messrs. Drake and Gorham in their country house installations, and they find that it effects a considerable economy, as during a considerable portion of the year the number of lights required is but small. The superintendence of the work during erection was carried out by Mr. A. A. Campbell Swinton.

Disappearing Lampposts.—An ingenious suggestion has been made to the Brussels authorities with regard to the electric lighting of their principal streets, and particularly of the Grand' Place, in which the Hôtel de Ville is situated. It has hitherto been objected to the plans for the electrical illumination of this square, that the poles on which the lights were hung, and all proposed improvements in the lamps, were out of harmony with the surrounding architecture, which is of an exceedingly interesting character (many of the buildings being in the old style), and were apt to be an eyesore in the daytime. It is now proposed that the light shall be shed upon the square from tall steel standards, which will be sunk in deep sheaths underground in daylight, and elevated by hydraulic pressure at dusk. Prizes of 1,000f. and 500f. are offered for the best design of lamppost.

An Enormous Microscope.—The Poeller Physical Optical Institute of Munich have under construction an enormous microscope for exhibition at Chicago in 1893. It will magnify to 16,000 diameters, or, as ordinarily fitted, to 11,000 diameters. An electric light of 11,000 c.p. is to be used for illuminating the image, which is to be projected on a screen. As the heat from this powerful light would derange the focus by expansion of the metal, an ingenious device is used to cool the metal. This is a small copper cylinder filled with liquid carbonic acid under a pressure of 350lb. to the square inch. It is connected with the microscope in such a manner that an electric regulator automatically opens a valve and allows a drop of the acid to escape in a spray on the metal to be cooled; the liquid immediately evaporates and produces intense cold. The whole cost of the instrument is said to be nearly £2,000.

High-Tension Continuous-Current System.—A correspondent of the *Times*, writing with reference to the use of high-tension continuous currents, states (apparently officially) that the Electric Installation and Maintenance Company, Limited, are about to supply the Crystal Palace and district with electricity on the system of a high-tension continuous current, with transformers and a reserve of accumulators, and that a similar system is also about being carried out for lighting the city of Oxford. The advantage of the system consists in being able to supply a whole town from one generating station, the low-tension distribution into the houses of consumers available both for light and power being made from small subsidiary stations, working automatically, and with little or no supervision. The first cost of this system is not greater than that of any other, while the cost of working, from the fact of the machinery being always on full load, is very economical.

Ipswich.—The chairman of the Ipswich Lighting Committee last week read a letter from Messrs. R. D. and J. B. Fraser, in which they agreed to erect at their own expense two electric arc lamps and brackets on their premises, each lamp to cost them £30. They also agree to provide electricity, necessary carbons, and attendance, for the said two arc lights of 500 c.p., and keep the same alight during the same hours as the other public lamps, for the next 10 years, if the committee pay £15 per annum. This

is a fraction over 1½d. an hour with an average of 10 hours per day. The present lamp and fittings to become Messrs. Fraser's absolute property, as those it is proposed to erect shall be. It was stated that some time since an arrangement was made for one lamp, the first cost of which was £26, and that the present lighting cost £10. 17s. 6d., against the proposed £15 ; but if two or three other street lamps could be extinguished, for each another £3 would be taken off. It was unanimously agreed to accept Messrs. Fraser's offer.

Growth of Electric Lighting.—Mr. W. H. Massey, writing to the *Times* with reference to the recent articles on the growth of electric lighting in London, says that it is an open secret that some of the existing companies cannot earn a dividend unless the price per Board of Trade unit is raised. The number of incandescent lamps may increase, but there is a decided tendency towards economy amongst the users of them, so that the earning power, so to speak, of each lamp will be steadily reduced ; and extensions may lead to actual loss instead of gain to the supply companies. Makers of dynamos, steam engines, and other apparatus are interested in showing the contrary ; but the fact is (Mr. Massey adds), nevertheless, as stated. With regard to the relative positions of England and America, he says that when in the United States last winter, he was surprised to find that even then in London alone there were more incandescent lamps than could be heard of in five of their largest cities (including New York) all put together.

Obituary.—We are sorry to have to report the death of Hon. Henry Cecil Raikes, the Postmaster-General of the United Kingdom, at the comparatively early age of 53. Mr. Raikes had long been ill, owing doubtless to the severe strain of Parliamentary Post Office duties, to say nothing of his other commercial work, for he was director in several companies. It was reported that he had been struck by lightning while riding in Hyde Park, and though it is perfectly true he was riding in the park during the thunderstorm, it is by no means certain that he really suffered a shock. It would, indeed, have been too grim that the chief user of electricity in England had suffered from the effects of electric shock. Mr. Raikes only came before the technical world by reason of his position as chief of the Post Office, and it would be idle to deny that considerable friction existed under his rule. He endeavoured to do his duty faithfully to his employer, the Government, and in him they have undoubtedly lost a painstaking and devoted servant.

Willson Dynamos.—*Industries* is sharply taken to task by Mr. Thos. L. Willson—the designer of the immense Willson dynamo for manufacture of aluminium in America—for its description and remarks thereon. In the first place, the output of the machine is 7,500 amperes at 100 volts instead of 15,000 at 50 volts, as incorrectly stated, and the current density is therefore only 2,500 amperes per square inch instead of 5,000 as stated. Again, with regard to Foucault currents, where enormous waste of power and great sparking was expected, Mr. Willson states that the Foucault currents are not a serious matter, as evidenced by the fact that the dynamo gives an efficiency of conversion of over 95 per cent. and runs absolutely without sparking. Where there is only one convolution of armature winding (as in this dynamo) there is minimum of sparking, and, as a fact, he says, the machines run quite sparkless at any load within their limits of capacity. Other little matters are also explained, demonstrating the worthiness of workmanship and design of this dynamo.

South Shields.—The Corporation of South Shields is desirous of receiving proposals from electric lighting companies and others for the laying down, manufacture, ... and working of the electric light in the borough ... pursuance of the provisional order granted by the ... of Trade to the Corporation, and which has recently re... the Royal assent. The Corporation is authorised ... down distributing mains within certain streets ... a period of two years, and offers are invited ... supplying certain streets with electric light, ... term of years and at a price per annum, and with ... conditions as may be stated in the proposal, and the ... may contain proposals for supplying the remainder of ... town or any parts thereof. Proposals to be sealed and ... to Mr. J. M. Moore, town clerk, 35, Market-place, S... Shields, by September 16, endorsed " Proposals for E... Lighting." Any person may obtain a copy of the A... Parliament confirming the order from Messrs. Eyre ... Spottiswoode, printers to the Queen, Fetter-lane, Lo... E.C.

The Invention of Fuses.—Here is the account ... invention of the fusible strip, as given in the Ame... technical press. Early in November, 1879, Edison ... invited a number of prominent men to see his three ... system and the carbon filament. Someone asked, "Wh... would happen if anyone put a bar of metal across ... wires?" "It would short-circuit the whole business, ... the thing would be a fizzle." Edison pondered the... saw the importance of the question, especially as so... the guests were known to be not too favourably disp... Finally he ordered the wire to be cut in several places, ... these breaks were connected with little strips of lead, ... whole laboratory being kept busy casting strips ... complete the story, it is said that a now well-known ... trician did actually suggest the playing of a joke by ... a bar across the wires, to which the assistant assented, ... only effect being that two or three lamps went out, but ... rest went on as usual. We wonder whether this was ... first use of the fusible strip, and more, why he d... patent it.

Electroculture.—Experiments have been carried ... in France, in Lot-et-Garonne, by M. Barat, upon the ap... cation of electricity to the culture of potatoes, tom... and hemp. A row of hemp, subjected to the influen... the electric current, produced a row of stalks 18in. hi... than those not electrified in the same time. A kilogra... (2·2lb.) of potatoes planted in the path of the current ... duced 21 kilogrammes of very large and healthy tu... while the unelectrified patches only gave 12½ kilogra... of medium size. The electrified tomatoes also became ... some eight days before the others. A curious fact ... been remarked by M. Barat in his experiments. If a q... tity of manure is near the positive pole, the constit... parts of this manure are transported towards ... negative pole, and their effects make themselves ... around a distance of some yards. This would seem ... be a fresh proof of the opinion long advanced upon the ... played by electricity in the growth of plants, an op... also adopted by M. Specnew, who has given some atte... to these phenomena : this is, that the action of the ele... current upon plants seems to consist in the more active ... solution of the organic principles existing in the soil wh... are thus brought within the reach of the roots.

Electric Welding Company.—We have se... times alluded to the fact that a large company was to ... floated to work the electric welding patents of Prof. El... Thomson. This company, under the name of the Ele... Welding Company, has been brought out this week, wi... capital of £460,000 in 45,000 ordinary shares, tak... 10 per cent. cumulative dividend, and 1,000 founders' sh... of £10 each, taking half the profit over 10 per cent. The ...

...) is of £260,000, one-third of which will be taken by ... vendors. The applications close on Saturday. The ...ctors are Sir Geo. Barclay Bruce (Past Pres. I.C.E.), ... Ashmead Bartlett, M.P., Captain A. H. Chapman ...ssrs. Clarke, Chapman, and Co.), William F. ...ch, J.P. (Vulcan Iron Works), and Joseph ...caid, M.I.C.E.; consulting engineer, Sir Frederick ...mwell; office, 2, Tokenhouse-buildings, E.C. We have ...ady commented several times upon the enterprise. It ...tated that besides the machine which the London and ...rth-Western Railway Company has running at Crewe, ...ding plants have been installed or are in course of instal...on on approbation or exhibit, as follows: One at the Lan...hire and Yorkshire Railway Works at Horwich; three at the ...rks of Messrs. Mather and Platt, at Salford; one at the ...rks of the Liverpool Condenser Company, Liverpool; one ... the works of Messrs. Clarke, Chapman, and Co., Gates...ad; one at Messrs. Dobson and Barlow's, of Bolton; one ... Messrs. Stewart and Clydesdale's, at Coatbridge, near ...asgow; one at Sir George Elliott's, at Cardiff; one has ...en ordered for Palmer's Shipbuilding and Iron Company, ...mited, of Jarrow-on-Tyne; and one may be seen in full ...ork at Fanshawe-street, Hoxton.

The Kousmine Diffusion Battery.—The diffusion ...ttery of M. Kousmine has been much used in Russia. ...y making use of the phenomenon of diffusion, M. ...ousmine has succeeded in overcoming the increase in ...ternal resistance of the bichromate of potash battery due ...) the formation of crystals on the positive electrode. The ...ositive carbon electrode consists of four strips attached to ...e lid of the battery. The negative zinc electrode consists ...f a circular grating resting on the bottom of the battery. ...y means of a funnel a 15deg. Beaumé solution of sulphuric ...cid is introduced until it just reaches the lower end of the ...arbon strips. A 6 to 7 per cent. solution of bichromate ...f potash is next introduced. The two liquids do not mix ...n account of the great difference in their densities. When ...he battery is short-circuited it is easy to see that ...hemical action only takes place close to the lower ...end of the carbon strips, which are gradually surrounded by a violet ring two or three millimetres deep. Above this region the bichromate solution retains its original colour. The bichromate solution being very weak, the chromic crystals dissolve as soon as they are formed, and the positive electrode is not covered by a deposit as in other batteries. The solution of these crystals, having a greater density than the surrounding liquid, falls to the bottom. The sulphate of zinc also falls to the bottom of the cell, causing more sulphuric acid to rise. A cell having the following dimensions has been tested by a committee of experts: Height, 20 centimetres; diameter, 15 centimetres; surface of zinc, 176 square centimetres; bichromate solution, 6 per cent.; sulphuric acid, 15deg. Beaumé. The committee reported that after having been circuited for 8½ hours on an external resistance of ·32 ohm, and then left on open circuit for 10½ hours, the cell continued to work for 4½ hours, when the circuit was again closed, and that it gave during 13 hours 36 ampere-hours for an expenditure of 48 grammes of zinc.

Gas v. Electricity in Ireland.—Mr. Ross, of Dungannon, president of the North of Ireland Association of Gas Managers, made some pertinent remarks as to electric lighting in the annual address last week at Belfast. He still decried the electric light as the "light of the future" in more than one sense, but seemed to think it a blessing in disguise, and that, in the end, the electric light will be found to have been of service to gas companies rather than the reverse. "On the one hand," said Mr. Ross, "a needed stimulus has been given to the improvement of the apparatus for burning gas; and, on the other hand, there has been created a demand for improved light, which we are in a condition to supply. The residents in large towns and cities especially will no longer be content with the modicum of street lighting which was considered quite satisfactory before the era of electric light experiments. Let the public be made aware that it is the local authorities, and not the gas companies, who are responsible for the street lighting, and that it rests with the former whether it shall be good or defective. The gas companies can supply light to any extent that may be ordered and paid for. No reasonable effort should be spared to secure the goodwill of the general body of consumers. Since writing the above, I observe that the electric light has been introduced into Carlow by Messrs. J. E. H. Gordon and Co. The same company have obtained the contract for lighting Larne; and water is to be the motive power. Of course, we shall have our eyes on Carlow in order to see whether or not it will be more successful than Dundalk. I also notice that the same firm have obtained a contract from the Portadown Town Commissioners to light several of the leading streets in that town. The electric light seems, therefore, to be advancing. Well, be it so. There is room enough for both it and gas, and I am not, and never was, the least doubtful that gas would still 'forge ahead,' and its consumption increase."

Stafford County Asylum.—A complete installation of electrical communication has lately been completed at the County Asylum, Stafford, which with regard to increased facilities for an alarm being given in case of fire and for the purposes of intercommunication between the various officials, will make it one of the foremost institutions in the country. The installation, which has been carried out by Messrs. W. A. Shaw and Co., of Heaton Chapel, near Stockport, electrical engineers, under the superintendence of Mr. Nevett, the resident clerk of works, consists of a system of fire alarm pulls, which are fixed in selected portions of the buildings. One of these being pulled out an alarm is immediately given by the ringing of 11 powerful electric bells, of special manufacture, which continue ringing until the pull is replaced. The position of the alarm is also indicated on six distinct indicators at the principal points of the buildings. In addition to this, the officials and attendants (who are members of the fire brigade) are alarmed separately of the danger by bells fixed near their rooms. There is also a complete telephone system by which the medical superintendent can communicate with the various officials throughout the buildings, and these instruments are arranged for intercommunication between the officials as may be desired. One of Gent and Co.'s inkmarking watchman's clocks, which registers the time when an electric push is pressed by the night watchmen, is also a feature of the installation. This registers from 18 different positions in the building. The work and material is of high quality, much of the latter having been specially manufactured, and from the tests that have been made by Mr. W. H. Cheadle, county surveyor, everything has been found to work satisfactorily and ready for use at any moment when required. The wire is of No. 16 gauge throughout, and upwards of 12 miles has been used in the work. Several false alarms of fire have been given to test the working and to exercise the fire brigade. It is hardly necessary to say how serious an event a fire would be at any institution of this kind, and any effort to minimise the danger of such an occurrence should be encouraged to the highest degree of perfection. Great praise is due to the asylum committee and Dr. Christie, the medical superintendent, for this and many other necessary and important improvements.

THE OERLIKON THREE-PHASE DYNAMOS.

The installation for the transmission of power by alternating rotary current from Lauffen to Frankfort having now become an accomplished fact, the description and illustration of the dynamos used in this installation will be doubly interesting to electrical engineers.

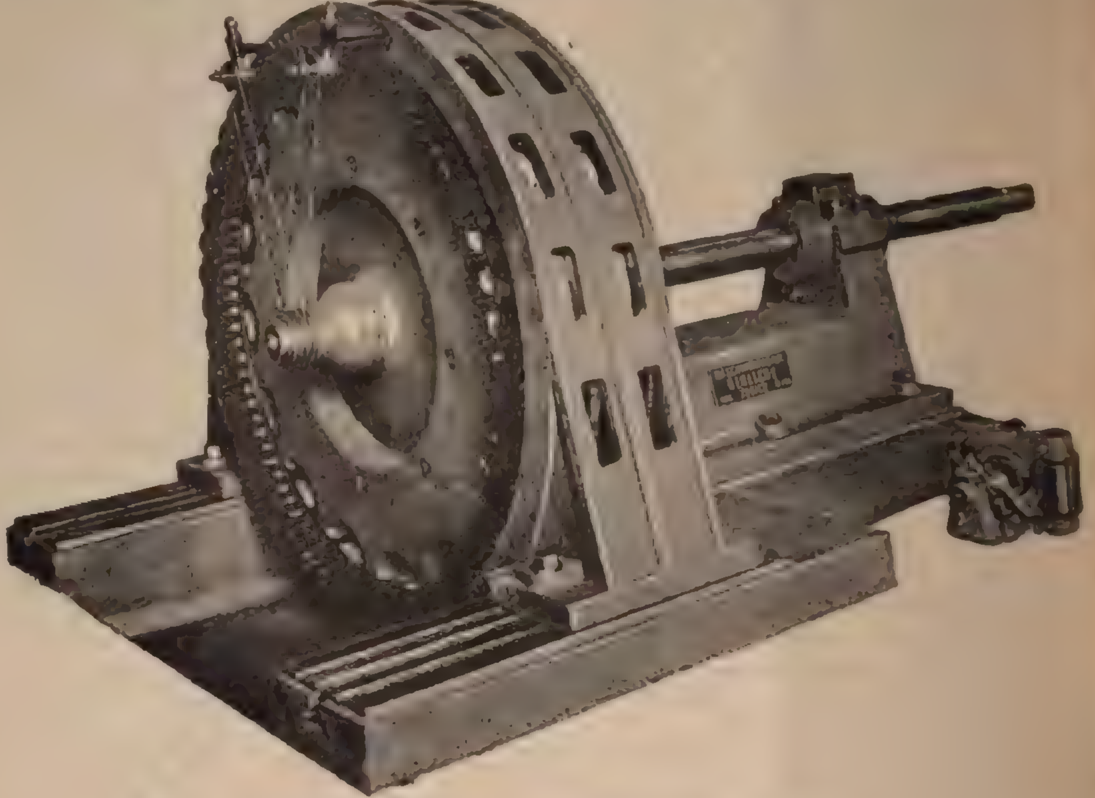

FIG. 1.—Oerlikon Three-Phase Rotary Current Dynamo, General View.

The electric transmission of power by means of electricity has now become an almost every day occurrence, but owing to the great distances by which the waterfalls—the usual sources of natural power—are separated from the centres of distribution, high pressures are necessary to

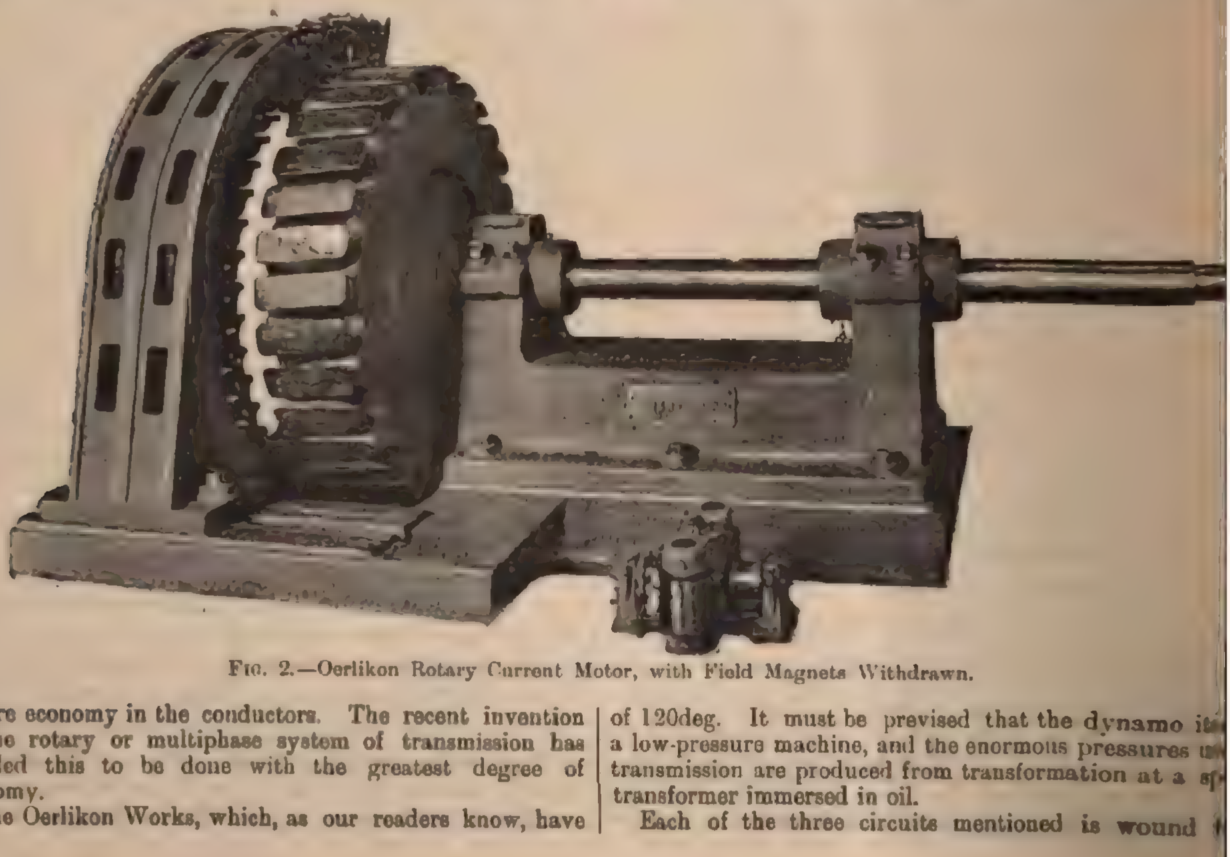

FIG. 2.—Oerlikon Rotary Current Motor, with Field Magnets Withdrawn.

ensure economy in the conductors. The recent invention of the rotary or multiphase system of transmission has enabled this to be done with the greatest degree of economy.

The Oerlikon Works, which, as our readers know, have long made a speciality of transmission of powe[r] having just completed the transmission plant at F... for 300 horse-power at 20,000 volts, a distan... miles, have several other plants which they are ... lay down on the multiphase system, with dyn... motors devised by Mr. C. E. L. Brown, chief eng... the Oerlikon Works.

A general view of the 300-h.p. multiphase dyn... seen in Fig. 1. This machine runs at 150 revolut... minute. The armature circuits are arranged in the ... we have already explained to give three separate alt... circuits, whose phases lag behind each other to the e... of 120deg. It must be prevised that the dynamo it... a low-pressure machine, and the enormous pressures u... transmission are produced from transformation at a sp... transformer immersed in oil.

Each of the three circuits mentioned is wound ...

of 50 volts to give a current of 1,400 amperes. To
e difficulties of contacts with such an enormous
the armature is made stationary, and the field
revolve. The conductors in the armature are
netres in diameter, and consist of massive copper
ulated by being slipped inside asbestos tubes, and
into holes punched out of the iron periphery.

There being three circuits, there are in all 96 bars on the armature. These three circuits are connected up to each other in the method familiar to electrical engineers in the Thomson-Houston arc dynamo. The core of the armature is surrounded by a frame of cast iron, and the whole can be moved along the bed-plate for repair or cleaning, leaving the field magnet exposed (see Fig. 2).

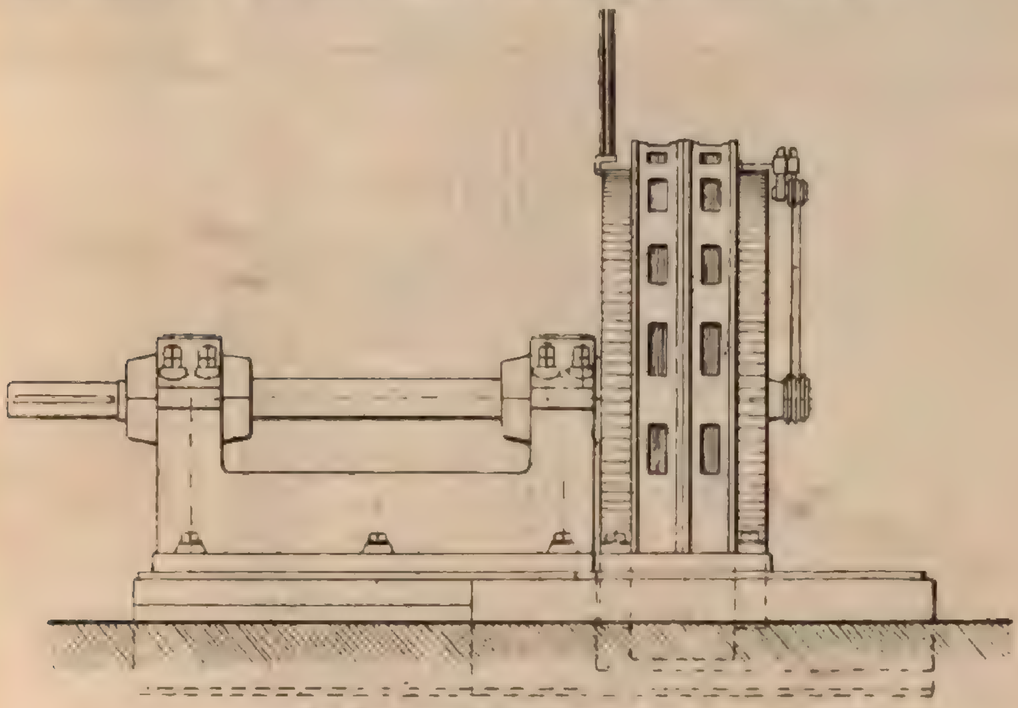

Fig. 3.—Section of Oerlikon Dynamo.

t currents, which would rise to enormous amounts
large conductors if arranged in the ordinary way,
this arrangement, avoided, and, in fact, tests made
ese buried conductors even up to 50 millimetres
did not show any loss by Foucault currents.

The exciting coils are wound upon a kind of iron wheel, two steel rims, each having 16 projecting teeth forming pole-pieces, are bolted to this pulley, one on each side. This arrangement permits the maximum utilisation of the magnetism, and both the weight of copper and the amount

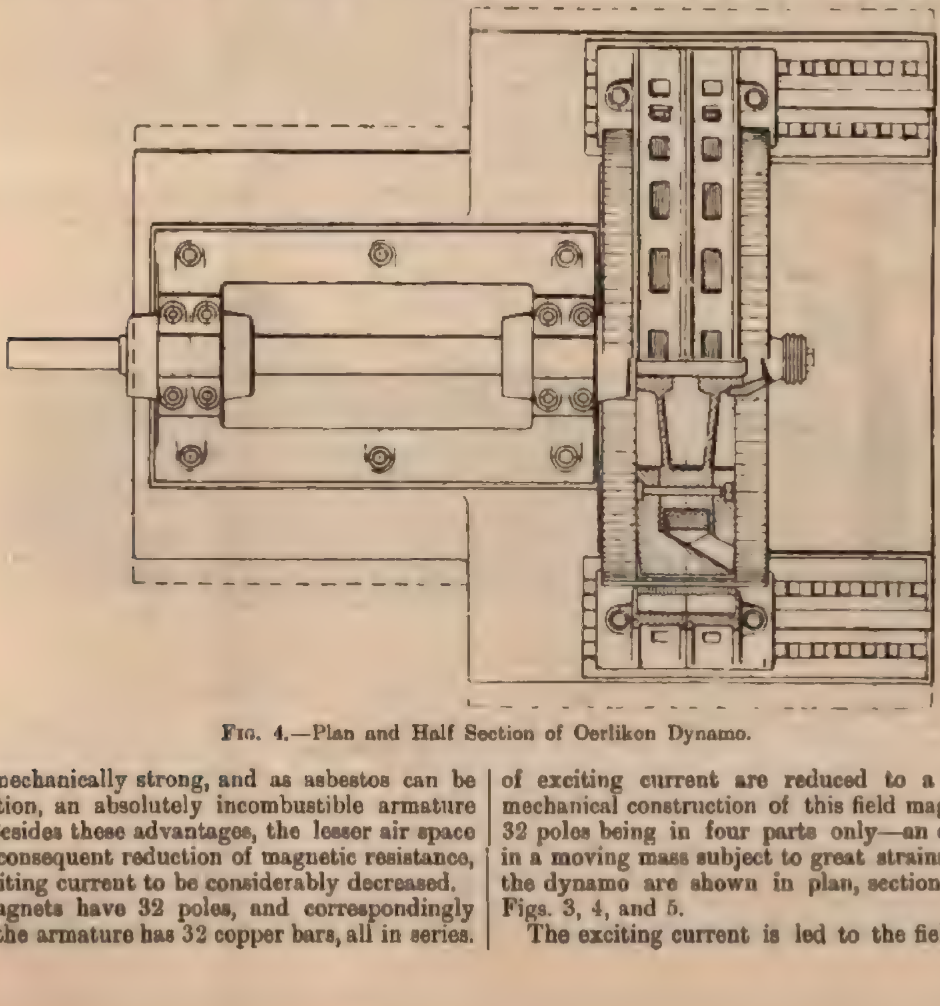

Fig. 4.—Plan and Half Section of Oerlikon Dynamo.

vice is mechanically strong, and as asbestos can be
insulation, an absolutely incombustible armature
ned. Besides these advantages, the lesser air space
l, with consequent reduction of magnetic resistance,
the exciting current to be considerably decreased.
field magnets have 32 poles, and correspondingly
cuit of the armature has 32 copper bars, all in series.

of exciting current are reduced to a minimum. The mechanical construction of this field magnet is simple, the 32 poles being in four parts only—an extreme advantage in a moving mass subject to great strains. The details of the dynamo are shown in plan, section, and elevation in Figs. 3, 4, and 5.

The exciting current is led to the field magnets by two

metallic bands, each passing round a grooved ring on the dynamo spindle, round a pulley connected to a terminal, as shown in Fig. 1. The armature has bearings on one side only, the huge spindle being carried on a double bracket bolted, as shown, to the bed-plate.

A dynamo of this type can equally well work as a synchronising motor, but it differs from the synchronising alternate-current motors already devised, inasmuch as it starts without difficulty under load.

The following figures will be read with interest. The total weight of copper on the field magnets is 300 kilo-

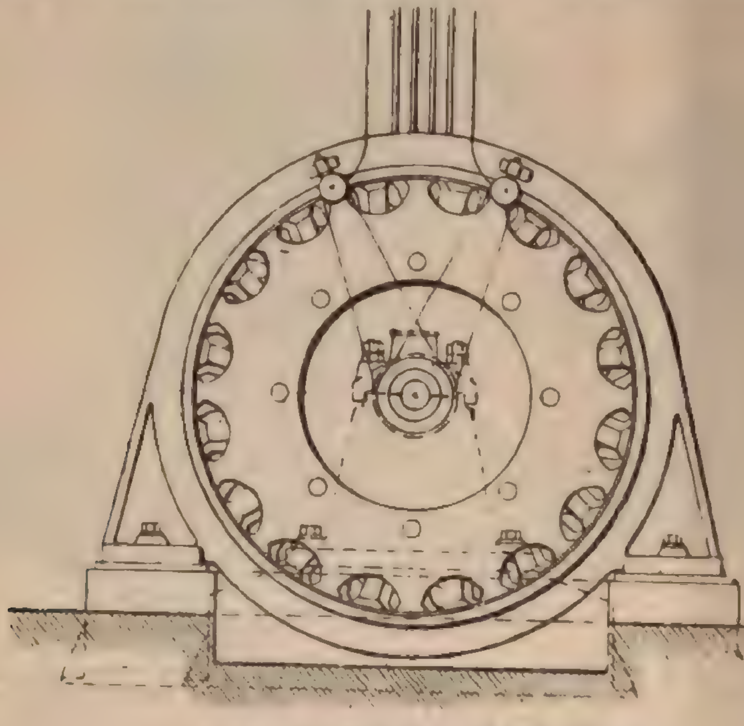

FIG. 5.—Side Elevation of Oerlikon Dynamo.

grammes (660lb.), which is only a small proportion of the weight of copper usually required on machines of this size. The exciting current required to give 50 volts on open circuit is only 100 watts—that is, ·05 per cent. of the output. At full load, by reason of the reaction of the armature, this amount is slightly increased, but it never has been found to be more than a fraction of 1 per cent. When running at full speed and at normal pressure, the losses by friction amount to 3,600 watts—about 1·6 or 1·7 per cent. of the maximum output.

The heating loss (C^2R) in the armature at full load amounts to 3,500 watts. Adding these losses, a commercial efficiency of quite 96 per cent. is obtained, and the losses being so small, the heating is negligible. The total weight without bed-plate is 9,600 kilogrammes (21,120lb., or nearly 10 tons).

Besides the Frankfort transmission plant, the Oerlikon Company have several dynamos of this type under construction. Dynamos are being built for a transmission of power over a distance of six miles at Heilbronn and also at Zurich. Three dynamos with vertical driving axles for co[...] direct to turbines, and two motors with vertical a[...] also being constructed for the supply of the w[...] to their own works at Oerlikon from a wate[...] distance of about 12 miles.

...EW (CARBONATE OF IRON) FAURE BATTERY.

The following particulars of the new carbonate of iron ...ttery of M. Camille A. Faure are given in the *Bulletin de ...lectricité* for August 20:

The battery is composed of wooden troughs, say, about ...ft. long by 3ft. 9in. high and 6ft. 6in. wide, enclosing ...me hundred or so double electrodes 6ft. 6in. wide. These ...ectrodes are constituted of an agglomerate of carbon ...tained by grinding up in a mill, drying, and then carbon...ing at 1,400deg. C. a paste composed of quarter by weight ... oats, quarter of bituminous coal, and half of very porous ...ayey earth. An agglomerate is thus obtained which is ...xtremely porous, with which one side of the electrodes ...nly is covered, the other receiving a coating of tar, ...endered entirely impermeable by rebaking. The porous ...ide of the electrode is covered with a large piece of netting ...r coarse sailcloth.

The space between these double electrodes is filled in ...ith granulated iron. The liquid used is salt water led in ...y tubes. The current is taken from two iron plates at ...he two extremities; the space between one of the plates ...nd the last electrode is filled in with coke or copper ...urnings of a sufficient conductivity to carry the current of ...,000 amperes, generated by this battery at a tension of ...bout 1·15 volts.

The elements of iron and carbon immersed in salt water ...NaCl) produce chlorate of iron, caustic soda, and hydrogen, with an E.M.F. of about ·30 volt; the hydrogen recombining with the oxygen increases this by ·40 volt, and the carbonisation of the soda by the carbonate of iron adds another ·30 volt, which is again increased ·15 volt by the use of reduced porous iron instead of solid iron. Thus the total E.M.F., according to M. Faure, is:

$$\cdot30 + \cdot40 + \cdot30 + \cdot15 = 1\cdot15 \text{ volts.}$$

In the electrolytic reaction the carbonate of iron and the chlorate of iron form carbonate of iron and chlorate of sodium, which is thus regenerated: the battery only uses the iron transformed into carbonate, which, as will be seen, is easily regenerated, as well as the carbonic acid used for this regeneration.

The cloth-covered porous surfaces constitute the positive faces of the electrodes; they are depolarised by the gases, which penetrate between the faces of each double electrode, which are arranged in cone shape, by holes placed in the bases of this cone, and of which the inert part—the nitrogen—escapes by the porous face, at the same time agitating the liquid.

The reduction of the carbonate of iron takes place in a retort charged with carbonate of iron, and traversed from top to bottom by gas reducers—CO, H, etc.—coming from a gasogene. Passing from the retort, these gases take fire at the contact of air, forming carbonic acid, which passes around the retort to the chimney, whence a portion of the gas is drawn by a pump, which forces it, after washing, into the battery. The air necessary for the combustion of the gasogene arrives, already heated, by a chimney, and the reduced spongy iron passes away cold by a channel placed at the base.

The installation of a Faure primary battery comprises, therefore, besides the battery properly so called—(1,000 elements)—a pump capable of forcing 1,000 cubic metres of carbonic acid per hour, a machine to agglomerate the carbonate of iron passed out of the channels, into bricks, and the reducing chamber.

According to M. Faure, the consumption of fuel in the retort is not more than 0·3lb. of coal per pound of iron used in the battery, or per horse-power hour at the battery terminals.

ON THE ELECTRIFICATION OF STEEL NEEDLE-POINTS IN AIR.*

BY A. P. CHATTOCK.

§ 1. As Faraday long ago put it, the discharge of electricity from a point into a gas may be looked upon as a particular case of sparking between a conductor, the point, and a non-conductor, the surrounding gas. It is, moreover, a particularly interesting form of discharge, as compared with that taking place between two conductors, from the fact that it seems more likely to throw light on the unsymmetrical behaviour of positive and negative electricity. For there is evidence which points to the surface of the electrode as the origin of that want of symmetry; and by experimenting with one electrode only, one is able, to a certain extent, to separate its effect on positive electricity from that on negative—such separation being impossible in the case of sparks between two conductors, as both effects are there necessarily present together.

The phenomena connected with discharge from points group themselves naturally under two heads: Those occurring before or at the beginning of discharge, and those occurring during the passage of electricity from the point. What follows refers to the first of these divisions only.

§ 2. When an earth-connected sewing-needle is placed with its end facing the centre of an insulated metal plate, and the latter is gradually electrified, there comes a point at which the needle begins to discharge on to the plate. This point, for given conditions, is very definite, and corresponds to a breaking down of some resistance between the needle and the plate. It seemed desirable to discover how much of the dielectric was concerned in this process. For this purpose measurements were made of the strength of the electrostatic field at the surface of the needle-point at the instant that discharge occurred, the distance of the plate from the needle being varied from 0·04 centimetre to 5 centimetres, while the needle was suspended in such a manner (§ 8) that the attraction between it and the plate could be determined.

Now the attraction is due of course to the tension in the lines of force which end at the surface of the needle; and since their direction is everywhere normal to the surface, it follows that if the needle be a true cylinder placed symmetrically with regard to the plate, the mechanical pulls of the lines of force upon its sides will balance, and the needle will be urged towards the plate with a force which depends only on the lines ending at its point (its other end being shielded from induction). Moreover, so long as the distance from the point to the plate is greater than a few times the diameter of the point, the distribution of electricity on the latter will be practically independent of that distance; and the strength of the electrostatic field just in front of the point will thus come to be proportional to the square root of the mechanical pull on the point. The needle becomes, in fact, its own electrometer, and measures the difference of potential between its point and the air a short distance from it.

In Table I. the value of the square root of the pull, P, in dynes on the point of a fine† sewing-needle at the instant of discharge are given for various distances, d, in centimetres between its point and a metal plate. The constancy of $\sqrt{P}$ speaks for itself.

It is true that an ordinary sewing-needle is not a perfect cylinder, but tapers gradually to its point, so that part of P must be due to lines of force on its sides; but this must be very small, for the density of charge on the sides is small compared with that at the point, and the force per square centimetre is proportional to the square of the density, and in addition to this the force on the sides has to be resolved into a direction almost at right angles to itself before it can affect P. Indeed, the very constancy of P, when d is varied, may be regarded as evidence that this part of P is negligible. (Other reasons are given in § 3.)

The two needles, A and B, on which the measurements were made were numbered alike by the makers, and the agreement in the values of $\sqrt{P}$ for the two is fairly close. This is the more satisfactory as the readings were taken under somewhat different conditions. The needle A was suspended in the larger of the two instruments described in § 8. It discharged on to a disc of tin 13 centimetres in diameter, with its edge protected by a ring of thick wire. The disc and the inside of the instrument were covered with a thin film of vaseline. The readings on B were taken with the small instrument. The disc in this case was a penny with its surface ground and polished. No vaseline was used.

The positive value of $\sqrt{P}$ for the two needles differ by about 3 per cent., whereas the negative values differ by 10 per cent. This is worth pointing out, as it is in accordance with what appears to be a general rule—viz., that the positive discharge is more constant and stable than the negative, and far less independent on the condition of the discharging point.

§ 3. One may, however, go further than simply showing the constancy of the discharge field at the point. In terms of the attraction of the needle and the radius of curvature of the point, it is possible to calculate its value.

Let $d\,a$ represent an element of area of the point's surface, and θ the angle between the direction of the lines of force at $d\,a$ and

the axis of the needle. Then, if the pull on the needle towards the plate be P,

$$P = \frac{1}{8\pi}\int f^2 \cos\theta \, d\,a$$

over the surface of the point, f being the field strength at $d\,a$.

Take, now, the case of a needle with its point ground to a hemisphere, and assume (what will not be strictly true) that the value of f is uniform all over it (see below). Then the above equation becomes

$$P = \frac{r^2 f^2}{8} \text{ or } f = \frac{\sqrt{8P}}{r}$$

where r is the radius of curvature of the point. The average value of $\sqrt{P}$ for positive discharge from needle B (Table I.) is 1·59. That for negative is 1·16. The value of r for so fine a needle is rather uncertain, as it tapers towards the point. Measured under a microscope it seems to lie between $1{\cdot}9 \times 10^{-3}$ and $2{\cdot}3 \times 10^{-3}$ centimetres. Taking the mean of these numbers one obtains the value of the field of force, f, close in front of the point

$$f = \frac{\sqrt{8P}}{r} = 2{,}140 \text{ E.S. units for } + \text{ discharge.}$$

$$= 1{,}560 \quad ,, \quad ,, \quad - \quad ,,$$

The highest measured value of f for discharge in air is, I believe, that obtained by Dr. Liebig for sparks between plates (*Phil. Mag.*, July, 1887, p. 106)—viz., 400 E.S. units for a spark-length of 0·0066 centimetre. This is much less than either of the above numbers, but the length of discharge at the point is probably much less than 0·0066 centimetre. The results may, moreover, be verified by calculation from potential data.

Although the value of f is so large at the surface of the needle-point, the lines of force diverge rapidly, and at a very short distance from the point the field becomes inappreciable. In other words, there occurs within this short distance a step of potential (v) which, if the point is hemispherical and small, may be taken as equal to $\frac{Q}{r}$, where Q is twice the charge on the hemisphere (Q, as already assumed, being uniformly distributed over the point).

In the same way, $f = \frac{Q}{r^2}$, whence

$$v = \frac{Q}{r} = f v = \sqrt{8P},$$

its value being thus independent of the somewhat uncertain quantity r.

For needle B,

$$v = 4{\cdot}5 \text{ E.S. units for } + \text{ discharge.}$$
$$= 3{\cdot}3 \quad ,, \quad ,, \quad - \quad ,,$$

In order to verify the above values of f, it will be conve[nient and] sufficient to show that these values of v calculated [from P are] in agreement with those calculated from potential me[asurements].

The column headed V, in Table I., gives the [step of] potential in E.S. units between the needle and the p[late]; except for the presence of the needle itself, the field [in] which it was placed would have consisted of parallel lines; [the] point of the needle was arranged in this experiment to [project] three or four millimetres beyond a flat screen of tinfoil [with a] small hole in it, and the distance from the tinfoil to the [disc (a] penny) on to which the needle discharged was small comp[ared with] the diameter of the disc, so long as the value of d was [less] than a centimetre. Even with the needle in position [the field] would be disturbed for a very small distance only round [the] point, on account of the extreme smallness of the latter. [Hence] V may be regarded as consisting of two parts—one [constant] (viz., v) and occurring in a small space close to the point; [the other] proportional to d for small values of d.

Taking the mean of the values of V for each value [of d, we] obtain the numbers plotted with d in Curves I.* The upp[er curve] is for positive discharge, the lower for negative. Up to a [distance] of something less than a centimetre from point to plate, the [values] of V lie very fairly on the straight lines ruled throug[h them]. V, a constant, is thus proportional to d; and the value[s of the] constants are of course to be found where the ruled lines [cut the] axis of V. These points are hardly distinguishable [from the] values (which are marked by crosses) of the step of potent[ial at the] point calculated above from P (viz., 4·5 and 3·3). The[re is,] indeed, a slight tendency to exceed these values; but the [agree]ment is certainly striking, considering the complete indep[endence] of the two methods of measurement.

The small amount (3 to 6 per cent.) by which the poten[tial] calculated from V exceeds that calculated from P may be a[ccounted] for, I think, by the fact that the lines of force from the point do not diverge quite as rapidly as calculation [assumes]. The parallel lines of the rest of the field keep them tog[ether and] so increase the real step of potential at the point without [increasing P] in proportion. To test this point I measured P for a needle [of] the same size as B, first suspending it in a parallel field, a[nd then] with its point at the centre of curvature of a spherical c[up]. In the first case, $\sqrt{P}$ was about 3 or 4 per cent. less than in the [second,] showing, as it seems to me in the light of what follows, th[at in the] parallel field f at the point was nearer the average val[ue of the] field through a small distance from the point-surface tha[n in the] radial field of the second case; and to about the same am[ount as] the above discrepancy requires.

This accounts, moreover, for the fact that needle B is [the] one which does not agree with the results of Table II. Its [value] ($f \times r^{0{\cdot}8}$) being 15·5 at a pressure of 76 centimetres.

As regards the measurement of potential in the above, th[e electro]meter described in § 8 was used; its constant being de[termined] by comparison with short sparks between brass knobs of [...] metres diameter.

The following are the readings taken :

Spark length.		V from spark-length (E.S. unit).	$\sqrt{\text{Electrometer reading}}$.	C[...] of [...]
Observed.	Corrected for flat plates.			
0·127	0·125	17·8	6·63	
,,	,,	,,	6·63	
0·190	0·186	24·8	9·23	
,,	,,	,,	9·39	

The values of V were taken from Dr. Liebig's pape[r already] referred to.

I think, then, it may be safely concluded that the attr[action of] a plate on a needle-point is practically due *only* to the line[s of force] ending at this point, even when the needle is not a perfect [hemisphere;] for a conical point could only have the effect of increasi[ng P, and] so making the step of potential calculated from it bigger t[han that] from V, whereas the reverse is the case. It is true that th[e field] must be greater at the centre of the point than at the sid[es of the] hemisphere. But this is what P chiefly depends upon, [and it is] also precisely here that discharge occurs and the valu[e of f is] required. Hence the connection established above betwe[en P and] f seems to be practically true, although the assumption [that f is] uniform over the point-surface is not.

In what follows, therefore, the values of f have in e[very case] been determined from P and r.

Effect of Curvature of Discharging Surface.

§ 4. Two conclusions appear, then, to result from the fo[regoing]. In the first place, the absence of discharge below a certain [step of] potential, which is constant for given conditions, impl[ies the] breaking down of some resistance before electricity can p[ass from] a point; and, secondly, the fact that f is independent of [d points] to the near neighbourhood or actual surface of the poin[t as the] seat of this resistance.

All this is in accordance with what is known regardi[ng the] discharge of electricity in gases, and is indeed only what on[e would] naturally have expected. It still remains to consider whe[ther the] resistance to discharge is to be sought in the gas itself, [or at the] surface of the point, or in both.

* These curves may appear when Mr. Chattock's paper [is pub]lished in the *Phil. Mag.* They were not shown at the Association Meeting.

In Curve IV., r is plotted with f at 76 centimetres pressure from this table.

The possible ways in which resistance may arise are, I think, all be included under three heads :

(*a*) It may exist in the gas itself, to a greater than molecular distance from the point. For this the gas must become possessed of something in the nature of structure round about the point—i.e., cease to be gas in the ordinary sense of the word—and the only kind of structure that suggests itself as likely is that of the polarised Grotthuss chains, which Prof. J. J. Thomson has used with such effect in his beautiful theory of striæ.

(*b*) It may exist at the surface of the metal only, and consist in the tearing away from the point by electrical force of electrified particles which are clinging to it (a special case of which is the forcing of charged particles through a non-conducting layer on the point.

(*c*) Or it may mean the pulling off of something in the nature of a film possessing surface-tension.

As a matter of fact (*b*) and (*c*) are two opposite extremes of the same phenomenon. In both, particles adhering to the point are pulled off, but the adhesion of (*b*) is normal to the surface only—i.e., between the particles and the metal—while in (*c*) it is tangential to the surface only—*i.e.*, between the particles themselves. An actual case would lie somewhere between the two, and probably much nearer to (*b*) than to (*c*).

Now in the case (*a*) of Grotthuss chains the field, f, at the point, as measured by the pull upon it, should increase as the sharpness of the point increases ; and for two reasons. In the first place, for chains of given length there will be some average strength of field required to break them, the value of which will always be less than that measured at the surface of the point on account of the divergence of the lines of force there ; and the difference between the measured and the average field will be more marked as the divergence—*i.e.*, the sharpness of the point—increases. Secondly, the chains will be shorter at a sharp point than at a blunt one on account of this same divergence ; and this again will necessitate a stronger field to break them, for much the same reason that a short piece of iron is harder to magnetise than a long one.

The same sort of variation of f with sharpness of point will occur in the case of (*c*), if the mechanical pull of the field on the point-surface be looked on as having to tear off a film stretched over it.

But to pull small particles off a point whose radius of curvature is large compared with their diameters will always require the same value of f. Hence (*b*) differs from (*a*) and (*c*) in requiring that f shall be independent of r.

The effect on f of altering r was therefore investigated. Steel needles were ground by a watchmaker to hemispherical points of different diameters and burnished with a hard steel-tool. The values of f in air were then determined for each at various pressures ; the instrument used being the smaller of the two described in § 8. Curves connecting air-pressure, p, and f were then plotted, and from these the numbers given in Table II. were taken. The values of f for positive discharge are given for three pressures—76, 40, and 20 centimetres of mercury. Those for negative discharge are only given as 20 centimetres. The reason being that the latter show a good deal of irregularity at higher pressures, seeming, as will be seen later, to depend largely on the condition of the point-surface, which the positive values do not. The values of f for needle C are inserted with queries, as they are almost certainly too high. The extreme fineness of its point necessitated a very rapid tapering to the sharpest part, so that a good deal of the measured pull must have been due to lines of force starting from its sides. This is borne out by the numbers in the four last columns.

Now, these columns show that below a point radius of $\frac{1}{10}$ millimetre f varies in close proportion with $r^{-0.8}$, and they consequently negative hypothesis (*b*). But they also negative (*c*), for the pull per square centimetre normal to a film of surface-tension, T, and radius of curvature r necessary to break it is proportional to T/r, and if this pull is to be supplied by f it follows that f^2 must be proportional to T/r, which gives $-0{\cdot}5$ instead of $-0{\cdot}8$ as the power of r with which f varies. Even $-0{\cdot}5$ is higher than can be assumed, for it is calculated on the supposition that there is no cohesion between the film and the point, and the existence of cohesion would still further reduce the power of r, as tending to bring the film nearer to class (*b*).

Resistance to discharge at a point is thus to be found in the surrounding gas, and is, therefore, practically reduced to the breaking down of Grotthuss chains, the length of which are not negligible compared with the radius of curvature of the point. I do not mean by this to exclude surface-resistance as a possible factor in discharge—indeed, what follows shews that it may be very appreciable ; but it is not the whole, nor, I believe, an important part, of the resistance at a clean point.

§ 5. After a point has been used for discharge for some time its resistance increases greatly, and when discharge occurs it begins with a suddenness and violence which is very suggestive of the bursting of a film. The effect is increased if the point be now reburnished (without regrinding), though this process makes it look as if it had never been used. For instance, Curves II. are those connecting the pressures of the air with f for needle H. The continuous curve A B represents f at the commencement of positive discharge, C D being for negative. The readings for these two curves were taken alternately, two at a time, the pressure being gradually increased. They correspond to an unused clean needle. The cloud of points (O for positive and × for negative discharge) was obtained on attempting to repeat the curves, and it was noticeable that each repetition increased the values of f, though the needle was well polished on dry wash-leather and rouge each time. Afterwards the needle was re-burnished, and the dotted curves E F (+) and G H (−) obtained, showing a still further increase of f and no less irregularity in its values than before.

The above, therefore, furnishes evidence of the growth of resistance at a point where it is used. That the current does not permanently clear the formation away in getting through is obvious from the readings ; but if a reading be taken quickly after another with a point in this condition, the second value of f is often slightly lower than the first ; as if the film had not had time to finish forming again after the first discharge. Now if this were so it would follow that the value of f, when the current stops, should be less than when it starts (for a used point only ; the two values agree closely for a clean one). To test this, needle H was again taken and the values of f determined for various air-pressures at the point when the current just stopped, the potential of the needle being gradually diminished until a high-resistance (7,000 ω) Elliot galvanometer between the needle and the earth stood at zero. The results are given in Curves III. A B and C D for the unused point are repeated from Curves II. for comparison. J K and L M are the new curves. They are marked by circles. The agreement between J K and A B could not be closer, and points unmistakably to a *temporary* cleaning of the point while current is flowing. L M, for negative discharge, is very curious—coinciding as it does with C D at low pressures, while it leaves it so completely higher up. It was noticeable that just in proportion as the two curves diverged, the stoppage of the current was marked by increasing suddenness. At high pressures it was impossible to get the needle to discharge at all with a small current ; either the flow was strong or it stopped altogether with a jerk—the same effect, though almost microscopic, being just perceptible at the cessation of positive discharge also. This being so, it follows that the values of f on the negative curve really correspond to a strong current and not to the point where the current stops. Hence their greater values. The sudden cutting off of the negative current was very striking, and suggested rather forcibly the covering over of the point by some sort of film that had been perforated by it. It is true that the positive discharge was hardly affected, but this is only an example of what has been already alluded to—the relatively greater instability of negative than of positive discharge.

(To be continued.)

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom............	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	8s. 8d	...	17s. 4d.
Other Places..................	4s. 10d.	...	9s. 8d.	..	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VII. inclusive, new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them ...ieving that they will get full value for the... ...

Specime... ...paper ... ...uest.

THE B. A.—CARDIFF MEETING.

The general opinion of the Cardiff meet... unfavourable. Perhaps a good deal of the ad... criticism has been caused by the weather, fo... more depressing time it would be hard to con... even if it was ordered from Brummagem. There is a feature

meetings becoming only too common, and that tantalising reference to an incomplete investiga- . We are told that the student or professor is ...ed upon something wonderful and important, ...hat at present the work is unfinished. So much ... is wasted, and before another year the half-...pleted experiments, never continued, are for-...n, and the section hears nothing further about ...

...matter more nearly concerning the managers of ...nical papers rather than their readers might ... be considered. Is it impossible, for example, ...stribute a complete list of *all* the papers to be ...ght before the section upon the first morning of ... meeting? As things are now managed, it is ...urgatorial task to report these technical ...ers. In fact, they could not and would not ...eported at all if authors and secretaries did ... hand over the MSS. It often happens, how-..., that more than one person wants a MS. ...he same time, and because of the physical im-...sibility of several men having the same MS. in ...erent places at the same time, a greater strain ...ut upon those who have to obtain the copy. If ... list of papers was known upon the first day, ...angements could be easily made with authors, and ... trouble experienced in this direction. We take ...or granted that the association is for the advance-...nt of science, and that authors require publicity for ...ir papers—a publicity, too, not given by a hurried ...ding before a dozen hearers, and an abstract ... the *Proceedings* published six months hence. ...ction G is by far the best managed as regards this ...ing of information. The greater part of the ...stracts are really ready when the meeting opens, ...d can be obtained upon application to the ...retaries.

The British Association would die of inanition ...re its proceedings to pass unnoticed for a couple of ...ars. It has no great claim upon the sympathies ... the public, and though *conversaziones* and picnics, ...rden parties and balls, may give the necessary ...creation while work is taking its share in ...e meeting, these social pleasures will not ...d to the advancement of science nor keep ...e association alive. There is a growing dissatis-...ction in allowing certain men to act pretty much ... they like. Papers from these men—scrappy, ...finished, or finished—are put before better papers ... other men. Time is wasted in the murmured ...ngratulations of a mutual admiration society, ...hile through these indulgences time cannot be ...und for the proper consideration of papers by ...her men.

That our interpretation of the necessities of the ...e is the correct one, and that it is the ...chnical press which advances science and not ...tional meetings, is proved by the result of the ...scussion on units held under the joint auspices of ...ctions A and G. The result really was that every ...eaker wanted some change or other—hardly any ...o agreed as to the necessity of any particular ...ange, and it was hoped the technical journals would take the matter up, and by some means so bring affairs to a focus that the Measurement Committee may next year be prepared with a proposal.

If we know aught of the feelings of technical papers, and the ideas of practical men, we imagine they will decline to trouble themselves about the matter. The desire for continued change is not to be commended. Better wait a little than change things too soon, a proceeding which would only necessitate another change almost immediately.

THE ELECTRICAL TRANSMISSION OF POWER AT FRANKFORT.

A Reuter's telegram from Frankfort-on-Main, August 25th, has the following important statement announcing the success of the Frankfort transmission of power—an announcement which may be fairly construed into one of the most eventful occurrences of the nineteenth century: "At noon to-day the electric lamps in the exhibition here were lighted for the first time by the current transmitted from the generating centre at the Lauffen falls of the Neckar, over 100 miles distant from this city. Yesterday the various authorities of Wurtemberg, Baden, Hesse, and Prussia, through whose territory the cable passes, formally took over the undertaking, and subsequently made it over to the General Electricity Company of Berlin and to the Oerlikon Machine Works of Switzerland, the constructors of the plant and electrical appliances. At eight o'clock in the evening the electrical current was transmitted from Lauffen along the cable, and it was found that the precautionary measures adopted along the cable line to ensure the safe transmission of the electric current were perfect. The representatives of the Wurtemberg authorities had assembled at Lauffen itself, the generating centre, while the representatives of the Baden and Hesse authorities, together with Herr von Miller, representing the exhibition, Herr Ebert, representing the Imperial Postal Department, Herr Strecker, the head engineer of the Telegraph Department, Herr von Dobrowolski, representing the electricity company, and Prof. Weber, of the Testing Committee, met at Eberbach, on the confines of Baden and Hesse, where they made some experiments. The transmission of the electrical current, derived from water power over a distance of 108 miles, is therefore an accomplished fact."

We may add that we learn that the voltage has already been run up to 16,000 volts, and the transferred power to over 80 h.p., used to supply 800 incandescent lamps and to drive a motor for pumping water to the artificial waterfall. The cost of the undertaking is given at £40,000.

CORRESPONDENCE.

"One man's word is no man's word
Justice needs that both be heard."

THE ST. PANCRAS EXHIBITION.

SIR,—If you will kindly publish this letter in your next issue we shall be greatly obliged, for although the matter is

neither edifying or important, since circulars containing an inaccurate statement concerning us have been printed and distributed, we feel bound to take some notice.

We, in common, we presume, with the rest of the exhibitors of the recent St. Pancras Electrical Exhibition, have received from Mr. Eccleston Gibb, the treasurer, a balance-sheet, accompanied by a circular, concluding thus: "If Messrs. Potter and Joel pay the balance still due from them—viz., £4. 10s. 10d.—this will be distributed at a future date."

The facts are as follows: We refused to pay our account in full, pointing out that, owing to the telephone exhibit having been placed in the ante-room which formed the sole means of access to and egress from our stand for the first week of the exhibition (especially during the evenings), visitors were quite unable to reach our exhibit, the throng in the telephone-room being so dense.

Any of the exhibitors will corroborate this, and it was fully recognised at the time by the committee, the telephones being ultimately removed to a corridor on the ground floor.

Needless to say, the success of our exhibit was seriously marred by this blunder on the part of those responsible for the arrangements.

On June 5 last we wrote to Mr. Eccleston Gibb regretting that a question had arisen with reference to our account and enclosing cheque in settlement, which cheque was accepted, and until the receipt of the circular in question we were under the impression that the matter was settled.

We think that the publication of such a statement as that complained of show very questionable taste on the part of Mr. Gibb, or whoever may be responsible, and, in conclusion, we beg to state that we do not for a moment admit that any balance is due from us, nor have we any intention of making any further payment.—Yours, etc.,

HENRY F. JOEL AND CO.

31, Wilson-street, E.C., August 26, 1891.

ELECTRICAL TRADES SECTION.—FRANKFORT EXHIBITION.

SIR,—The sub-committee recommends that gentlemen joining the party in connection with the Electrical Trades Section of the London Chamber of Commerce should travel *viâ* Dover and Ostend, leaving Holborn Viaduct Station by the train at 10 o'clock a.m. on Saturday, the 5th September. Each member of the party should provide himself with the necessary travelling ticket, and it is recommended that such tickets be obtained through Messrs. Cook and Son, Ludgate-circus, E.C., the fare being, *viâ* Dover and Ostend, £5. 16s. first-class return, available 30 days. The ticket should be taken on or before the 2nd September, and in the event of this being done, Messrs. Cook and Son will engage reserved railway carriages between London and Frankfort, and members are requested to specify that they belong to the Electrical Trades Section party. Members are further notified that ladies may be included in the party.

With regard to hotel accommodation the sub-committee could not well engage definitely sufficient rooms beforehand for the entire party, but the committee suggests to members to adhere to the following suggestions, in which case they will no doubt be suited for rooms. They can either buy coupons for rooms and dinners, through Messrs. Cook and Sons, for the Swan Hotel, Frankfort, and if such coupons are taken at the same time as the ticket, Messrs. Cook will take steps to reserve sufficient and good accommodation. Or members of the party can secure rooms at the Britannia Hotel, or Hotel Romscher Kaiser, if they write to the proprietors about a week beforehand, mentioning that they belong the Electrical Trades Section party.

The committee is in communication with the president of the Electro-Technical Society of Frankfort with respect to tickets for the various events in connection with the exhibition and congress, and ge[...] will be advised, if necessary, as to what special a[...] can be made in this respect.—Yours, etc.,

KENRIC[...] [...]cretary.

THE BRITISH ASSOCIATION AT CARDI

PRESIDENTIAL ADDRESS BY WILLIAM HUG
D.C.L. (OXON.), LL.D. (CANTAB., EDIN., ET DUBL
(LUGD. BAT.), F.R.S., F.R.A.S., HON. F.R.S.E.,
SPONDANT DE L'INSTITUT DE FRANCE.

(*Continued from page 186.*)

Prof. Rowland looks to the solar lines which are
for as a means of enabling him to discover such ne
elements as still lurk in rare minerals and earths, by
their spectra directly with that of the sun. He has alre
yttrium spectroscopically into three components, and
two. The comparison of the results of this independ
method with the remarkable but different conclusions
Lecoq de Boisbaudran and Mr. Crookes have been led
from spectroscopic observation of these bodies when
molecular bombardment in a vacuum tube, will be
much interest. It is worthy of remark that as our
the spectrum of hydrogen in its complete form cam
the stars, it is now from the sun that chemistry is pro
to be enriched by the discovery of new elements.

In a discussion in the Bakerian lecture for 1885 of wh
up to that time of the sun's corona, I was led to the
that the corona is essentially a phenomenon similar in
its formation to the tails of comets—namely, that it
the most part probably of matter going from the sun
action of a force, possibly electrical, which varies as the
and can therefore in the case of highly-attenuated ma
master the force of gravity even near the sun. Thou
the coronal particles may return to the sun, those whi
long rays or streamers do not return; they separ
become too diffused to be any longer visible, and may
furnish the matter of the zodiacal light, which other
received a satisfactory explanation. And further, if
exist at the sun, the changes of terrestrial magnetism
to direct electric action, as the earth moves throug
inductive force.

These conclusions appear to be in accordance broadly
lines along which thought has been directed by the
subsequent eclipses. Prof. Schuster takes an essentiall
view, and suggests that there may be a direct electric
between the sun and the planets. He asks further w
sun may not act like a magnet in consequence of its
about its axis. Prof. Bigelow has recently treated th
forms by the theory of spherical harmonics, on the
that we see phenomena similar to those of free electricity,
being lines of force, and the coronal matter discharged fro
or at least arranged or controlled by these forces. At the
ties of the streams, for some reasons, the repulsive pow
lost, and gravitation set in, bringing the matter back to
The matter which does leave the sun is persistently tran
the equatorial plane of the corona. In fact, the zodiacal
be the accumulation at great distances from the sun
equator of such like material. Photographs on a large
be desirable for the full development of the conclusions
follow from this study of the curved forms of the coronal
Prof. Schaeberle, however, considers that the coronal p
may be satisfactorily accounted for on the supposition
corona is formed of streams of matter ejected mainly from
zones with great initial velocities, but smaller than 38
second. Further, that the different types of the corona
the effects of perspective on the streams from the earth's
the time relatively to the plane of the solar equator.

Of the physical and the chemical nature of the coron
we know very little. Schuster concludes, from an exam
the eclipses of 1882, 1883, and 1886, that the continuous
of the corona has the maximum of actinic intensity
considerably towards the red when compared with the
of the sun, which shows that it can only be due in sma
solar light scattered by small particles. The lines of cal
of hydrogen do not appear to form part of the normal sp
the corona. The green coronal line has no known repr
in terrestrial substances, nor has Schuster been able to
any of our elements in the other lines of the corona.

The spectra of the stars are almost infinitely diversified
can be arranged with some exceptions in a series in
adjacent spectra, especially in the photographic region, ar
distinguishable, passing from the bluish-white stars, li
through stars more or less solar in character, to stars wi
spectra, which divide themselves into two apparently ind
groups, according as the stronger edge of the bands is to
red or the blue. In such an arrangement the sun's place
the middle of the series.

At present a difference of opinion exists as to the di
the series in which evolution is proceeding, whether
condensation white stars pass into the orange and red
whether these more coloured stars are younger and wi
white by increasing age. The latter view was suggested
stone Stoney in 1867.

About 10 years ago Ritter, in a series of papers, di
behaviour of gaseous masses during condensation, and th
resulting constitution of the heavenly bodies. Accordi
a star passes through the orange and red stages twice, fi
comparatively short period of increasing temperature
minates in the white stage, and a second time during
red stage of gradual cooling. He suggested that the

stars may correspond to these different periods: the
being those in which the stronger edge of the dark
rards the blue, the other banded stars, which are rela-
luminous and few in number, being those which are
g extinction through age.

, a similar evolutional order has been suggested, which
on the hypothesis that the nebulæ and stars consist of
eteoric stones in different stages of condensation. More
e view has been put forward that the diversified spectra
do not represent the stages of an evolutional progress,
for the most part to differences of original constitution.
minutes which can be given to this part of the address
ient for a discussion of these different views. I purpose,
to state briefly, and with reserve as the subject is
me of the considerations from the characters of their
ich appeared to me to be in favour of the evolutional
ich I arranged the stars from their photographic spectra
is order is essentially the same as Vogel had previously
his classification of the stars in 1874, in which the
, which are most numerous, represent the early adult
ersistent stage of stellar life, the solar condition that of
ity and of commencing age; while in the orange and
ith banded spectra we see the setting in and advance of
But this statement must be taken broadly, and not as
hat all stars, however different in mass and possibly to
extent in original constitution, exhibit one invariable
of spectra.

pectra of the white stars the dark metallic lines are
nconspicuous, and occasionally absent, at the same time
rk lines of hydrogen are usually strong, and more or
upon a continuous spectrum, which is remarkable for
y at the blue end. In some of these stars the hydrogen
ther lines are bright, and sometimes variable.

eater or less prominence of the hydrogen lines, dark or
haracteristic of the white stars as a class, and diminishes
rith the incoming and increase in strength of the other
re probably justified in regarding it as due to some
which occur naturally during the progress of stellar
t to a peculiarity of original constitution.

ce a strong absorption spectrum a substance must be
icular temperature at which it is notably absorptive;
r, this temperature must be sufficiently below that of
behind from which the light comes for the gas to appear,
special rays are concerned, as darkness upon it. Con-
e high temperature to which hydrogen must be raised
n show its characteristic emission and absorption, we
bly be right in attributing the relative feebleness or
the other lines, not to the paucity of the metallic
it rather to their being so hot relatively to the sub-
ind them as to show feebly, if at all, by reversion.
e of things would more probably be found, it seems to
ditions anterior to the solar stage. A considerable
he sun would probably give rise to banded spectra due
ds, or to more complex molecules, which might form
ndensing points of the vapours.

and stars are generally regarded as consisting of glowing
rounded by a photosphere where condensation is taking
temperature of the photospheric layer from which the
t of the radiation comes being constantly renewed from
natter within.

rface the convection currents would be strong, pro-
onsiderable commotion, by which the different gases
ixed and not allowed to retain the inequality of pro-
different levels due to their vapour densities.

conditions of the radiating photosphere and those of
ove it, on which the character of the spectrum of a
s, will be determined, not only by temperature, but
force of gravity in these regions; this force will be
star's mass and its stage of condensation, and will
ater as the star continues to condense.

e of the sun the force of gravity has already become
the surface that the decrease of the density of the gases
remely rapid, passing in the space of a few miles from
pressure to a density infinitesimally small; conse-
temperature gradient at the surface, if determined
pansion, must be extremely rapid. The gases here,
e exposed to the fierce radiation of the sun, and unless
sparent would take up heat, especially if any solid or
icles were present from condensation or convection

se causes, within a very small extent of space at the
he sun, all bodies with which we are acquainted should
ndition in which the extremely tenuous gas could no
a visible spectrum. The insignificance of the angle
y this space as seen from the earth should cause the
f the solar atmosphere to appear defined. If the
hich we see be that of the sun proper, the matter above
to be regarded as in an essentially dynamical con-
ssemblage, so to speak, of gaseous projectiles for the
lling back upon the sun after a greater or less range
But in any case it is within a space of relatively small
e sun, and probably in the other solar stars, that the
hich is manifested by dark lines is to be regarded as
s

ackward in the star's life, we should find a gradual
f gravity at the surface, a reduction of the temperature
far as it was determined by expansion, and convection
less violence producing less interference with the pro-
uantities of gases due to their vapour densities, while
f eruptions would be more extensive.

At last we might come to a state of things in which, if the star were hot enough, only hydrogen might be sufficiently cool relatively to the radiation behind to produce a strong absorption. The lower vapours would be protected, and might continue to be relatively too hot for their lines to appear very dark upon the continuous spectrum; besides, their lines might be possibly to some extent effaced by the coming in under such conditions in the vapours themselves of a continuous spectrum.

In such a star the light radiated towards the upper part of the atmosphere may have come from portions lower down of the atmosphere itself, or at least from parts not greatly hotter. There may be no such great difference of temperature of the low and less low portions of the star's atmosphere as to make the darkening effect of absorption of the protected metallic vapours to prevail over the illuminating effect of their emission.

It is only by a vibratory motion corresponding to a very high temperature that the bright lines of the first spectrum of hydrogen can be brought out, and by the equivalence of absorbing and emitting power that the corresponding spectrum of absorption should be produced; yet for a strong absorption to show itself, the hydrogen must be cool relatively to the source of radiation behind it, whether this be condensed particles or gas. Such conditions, it seems to me, should occur in the earlier rather than in the more advanced stages of condensation.

The subject is obscure, and we may go wrong in our mode of conceiving of the probable progress of events, but there can be no doubt that in one remarkable instance the white-star spectrum is associated with an early stage of condensation.

Sirius is one of the most conspicuous examples of one type of this class of stars. Photometric observations combined with its ascertained parallax show that this star emits from 40 to 60 times the light of the sun, even to the eye, which is insensible to ultra-violet light, in which Sirius is very rich, while we learn from the motion of its companion that its mass is not much more than double that of our sun. It follows that unless we attribute to this star an improbably great emissive power, it must be of immense size, and in a much more diffuse and therefore an earlier condition than our sun; though probably at a later stage than those white stars in which the hydrogen lines are bright.

A direct determination of the relative temperature of the photospheres of the stars might possibly be obtained in some cases from the relative position of maximum radiation of their continuous spectra. Langley has shown that through the whole range of temperature on which we can experiment, and presumably at temperatures beyond, the maximum of radiation power in solid bodies gradually shifts upwards in the spectrum from the infra-red through the red and orange, and that in the sun it has reached the blue.

The defined character as a rule of the stellar lines of absorption suggests that the vapours producing them do not at the same time exert any strong power of general absorption. Consequently we should probably not go far wrong, when the photosphere consists of liquid or solid particles, if we could compare select parts of the continuous spectrum between the stronger lines or where they are fewest. It is obvious that if extended portions of different stellar spectra were compared, their true relation would be obscured by the line-absorption.

The increase of temperature, as shown by the rise in the spectrum of the maximum of radiation, may not always be accompanied by a corresponding greater brightness of a star as estimated by the eye, which is an extremely imperfect photometric instrument. Not only is the eye blind to large regions of radiation, but even for the small range of light that we can see the visual effect varies enormously with its colour. According to Prof. Langley, the same amount of energy which just enables us to perceive light in the crimson at A would in the green produce a visual effect 100,000 times greater. In the violet the proportional effect would be 1,600, in the blue 62,000, in the yellow 28,000, in the orange 14,000, and in the red 1,200. Captain Abney's recent experiments make the sensitiveness of the eye for the green near F to be 750 times greater than for red about C. It is for this reason, at least in part, that I suggested in 1864, and have since shown by direct observation that the spectrum of the nebula in Andromeda, and presumably of similar nebulæ, is in appearance only wanting in the red.

The stage at which the maximum radiation is in the green, corresponding to the eye's greatest sensitiveness, would be that in which it could be most favourably measured by eye photometry. As the maximum rose into the violet and beyond, the star would increase in visual brightness, but not in proportion to the increase of energy radiated by it.

The brightness of a star would be affected by the nature of the substance by which the light was chiefly emitted. In the laboratory solid carbon exhibits the highest emissive power. A stellar stage in which radiation comes, to a large extent, from a photosphere of the solid particles of this substance would be favourable for great brilliancy. Though the stars are built up of matter essentially similar to that of the sun, it does not follow that the proportion of the different elements is everywhere the same. It may be that the substances condensed in the photospheres of different stars may differ in their emissive powers, but probably not to a great extent.

All the heavenly bodies are seen by us through the tinted medium of our atmosphere. According to Langley, the solar stage of stars is not really yellow, but even as gauged by our imperfect eyes, would appear bluish-white if we could free ourselves from the deceptive influences of our surroundings.

From these considerations it follows that we can scarcely infer the evolutional stages of the stars from a simple comparison of their eye-magnitudes. We should expect the white stars to be, as a class, less dense than the stars in the solar stage. As great mass might bring in the solar type of spectrum at a relatively

earlier time, some of the brightest of these stars may be very massive and brighter than the sun—for example, the brilliant star Arcturus. For these reasons the solar stars should not only be denser than the white stars, but perhaps, as a class, surpass them in mass and eye-brightness.

It has been shown by Lane that, so long as a condensing gaseous mass remains subject to the laws of a purely gaseous body, its temperature will continue to rise.

The greater or less breadth of the lines of absorption of hydrogen in the white stars may be due to variations of the depth of the hydrogen in the line of sight, arising from the causes which have been discussed. At the sides of the lines the absorption and emission are feebler than in the middle, and would come out more strongly with a greater thickness of gas.

The diversities among the white stars are nearly as numerous as the individuals of the class. Time does not permit me to do more than to record that in addition to the three sub-classes into which they have been divided by Vogel, Scheiner has recently investigated minor differences as suggested by the character of the third line of hydrogen near G. He has pointed out, too, that so far as his observations go the white stars in the constellation of Orion stand alone, with the exception of Algol, in possessing a dark line in the blue which has apparently the same position as a bright line in the great nebula of the same constellation; and Pickering finds in his photographs of the spectra of these stars dark lines corresponding to the principal lines of the bright-line stars, and the planetary nebulæ with the exception of the chief nebular line. The association of white stars with nebular matter in Orion, in the Pleiades, in the region of the Milky Way, and in other parts of the heavens, may be regarded as falling in with the view that I taken.

In the stars possibly further removed from the white class than our sun, belonging to the first division of Vogel's third class, which are distinguished by absorption bands with their stronger edge towards the blue, the hydrogen lines are narrower than in the solar spectrum. In these stars the density-gradient is probably still more rapid, the depth of hydrogen may be less, and possibly the hydrogen molecules may be affected by a larger number of encounters with dissimilar molecules. In some red stars with dark hydrecarbon bands the hydrogen lines have not certainly been observed; if they are really absent, it may be because the temperature has fallen below the point at which hydrogen can exert its characteristic absorption; besides, some hydrogen will have united with the carbon. The coming in of the hydrocarbon bands may indicate a later evolution stage, but the temperature may still be high, as acetylene can exist in the electric arc.

A number of small stars, more or less similar to those which are known by the names of their discoverers, Wolf and Rayet, have been found by Pickering in his photographs. These are remarkable for several brilliant groups of bright lines, including frequently the hydrogen lines and the line D_3, upon a continuous spectrum strong in blue and violet rays, in which are also dark lines of absorption. As some of the bright groups appear in his photographs to agree in position with corresponding bright lines in the planetary nebulæ, Pickering suggests that these stars should be placed in one class with them, but the brightest nebular line is absent from these stars. The simplest conception of their nature would be that each star is surrounded by a nebula, the bright groups being due to gaseous matter outside the star. Mr. Roberts, however, has not been able to bring out any indication of nebulosity by prolonged exposure. The remarkable star η Argus may belong to this class of the heavenly bodies.

In the nebulæ, the elder Herschel saw portions of the fiery mist or "shining fluid" out of which the heavens and the earth had been slowly fashioned. For a time this view of the nebulæ gave place to that which regarded them as external galaxies, cosmical "sandheaps," too remote to be resolved into separate stars; though indeed, in 1858, Mr. Herbert Spencer showed that the observations of nebulæ up to that time were really in favour of an evolutional progress.

In 1864 I brought the spectroscope to bear upon them; the bright lines which flashed upon the eye showed the source of the light to be glowing gas, and so restored these bodies to what is probably their true place, as an early stage of sidereal life.

At that early time our knowledge of stellar spectra was small. For this reason partly, and probably also under the undue influence of theological opinions then widely prevalent, I unwisely wrote in my original paper in 1864, "that in these objects we no longer have to do with a special modification of our own type of sun, but find ourselves in presence of objects possessing a distinct and peculiar plan of structure." Two years later, however, in a lecture before this association, I took a truer position. "Our views of the universe," I said, "are undergoing important changes; let us wait for more facts with minds unfettered by any dogmatic theory, and therefore free to receive the teaching, whatever it may be, of new observations."

Let us turn aside for a moment from the nebulæ in the sky to the conclusions to which philosophers had been irresistibly led by a consideration of the features of the solar system. We have before us in the sun and planets obviously not a haphazard aggregation of bodies, but a system resting upon a multitude of relations pointing to a common physical cause. From these considerations Kant and Laplace formulated the nebular hypothesis, resting it on gravitation alone, for at that time the science of the conservation of energy was practically unknown. These philosophers showed how, on the supp[illegible] that the space now occupied by the solar system was once fill[illegible] rous mass, the formation of the sun and [illegible] could [illegible] ccounted for.

By a tota[illegible] ethod [illegible] ern science traces the solar sy[illegible] state of things at the beginning. According to Helmholtz, the sun's [illegible] tained by the contraction of his mass, at the rate [illegible] a year. Whether at the present time the sun is [illegible] colder we do not certainly know. We can reason back [illegible] when the sun was sufficiently expanded to fill the [illegible] occupied by the solar system, and was reduced to a [illegible] nebula. Though man's life—the life of the race, [illegible] short to give us direct evidence of any distinct stage [illegible] a process, still the probability is great that the nebular [illegible] especially in the more precise form given to it [illegible] represent broadly, notwithstanding some difficulties, the [illegible] of events through which the sun and planets have [illegible]

The nebular hypothesis of Laplace requires a [illegible] fluid which at successive epochs become unstable [illegible] motion and left behind rings—or more probably, perhaps [illegible] of matter from the equatorial regions.

The difficulties to which I have referred have sugge[illegible] thinkers a different view of things, according to [illegible] necessary to suppose that one part of the system [illegible] supports another. The whole may consist of a [illegible] crete bodies even if these bodies be the ultimate [illegible] matter. The planets may have been formed by [illegible] accretion of such discrete bodies. On the view that [illegible] of the condensing solar system consisted of separate [illegible] masses, we have no longer the fluid pressure which is [illegible] part of Laplace's theory. Fay, in his theory of [illegible] meteorites, has to throw over this fundamental idea of [illegible] hypothesis, and he formulates instead a different [illegible] events in which the outer planets were formed last—a [illegible] has difficulties of its own.

Prof. George Darwin has recently shown, from an [illegible] of the mechanical conditions of a swarm of meteorites [illegible] certain assumptions a meteoric swarm might behave [illegible] gas, and in this way bring back the fluid-pressure [illegible] one part of the system on the other, which is required [illegible] theory. One chief assumption consists in supposing [illegible] inelastic bodies as meteoric stones might attain the [illegible] ticity of a high order which is necessary to the theory [illegible] sudden volatilisation of a part of their mass at an [illegible] which what is virtually a violent explosive is introd[illegible] the two colliding stones. Prof. Darwin is careful to [illegible] it must necessarily be obscure as to how a small [illegible] matter can take up a very large amount of energy [illegible] fraction of a second.

Any direct indications from the heavens themselves [illegible] slight, are of so great value, that I should perhaps in [illegible] tion call attention to a recent remarkable photograph [illegible] Roberts of the great nebula in Andromeda. On the [illegible] seem to have presented to us some stage of cosmical [illegible] gigantic scale. The photograph shows a sort of whirlp[illegible] ance of the luminous matter which is distributed in a pl[illegible] to the line of sight, in which a series of rings of bright [illegible] rated by dark spaces, greatly foreshortened by [illegible] surround a large undefined central mass. We are igno[illegible] parallax of this nebula, but there can be little doubt [illegible] looking upon a system very remote, and therefore of a [illegible] great beyond our power of adequate comprehension. T[illegible] of this nebula, in whatever state it may be, app[illegible] distributed, as in so many other nebulæ, in rings or spirals [illegible] and to suggest a stage in a succession of evolutional [illegible] inconsistent with that which the nebular hypothesis req[illegible] liken this object more directly to any particular stage [illegible] formation of the solar system would be "to compare th[illegible] with small," and might be indeed to introduce a false [illegible] but on the other hand, we should err through an excess [illegible] if we did not accept the remarkable features brought to [illegible] this photograph as a presumptive indication of a progress [illegible] in cosmical history following broadly upon the lines of [illegible] theory.

The old view of the original matter of the nebulæ, th[illegible] sisted of a "fiery mist,"

> "a tumultuous cloud
> Instinct with fire and nitre,"

fell at once with the rise of the science of thermodyna[illegible] 1854 Helmholtz showed that the supposition of an orig[illegible] condition of the nebulous stuff was unnecessary, since [illegible] mutual gravitation of widely-separated matter we have [illegible] potential energy sufficient to generate the high temperat[illegible] sun and stars. We can scarcely go wrong in attributing [illegible] of the nebulæ to the conversion of the gravitational [illegible] shrinkage into molecular motion.

The idea that the light of comets and of nebulæ may be [illegible] succession of ignited flashes of gas from the encounters of [illegible] stones was suggested by Prof. Tait, and was brought to [illegible] of this association in 1871 by Sir William Thomson in [illegible] dential address.

The spectrum of the bright-line nebulæ is certainly [illegible] spectrum as we should expect from the flashing by col[illegible] meteorites similar to those which have been analysed in o[illegible] tories. The strongest lines of the substances which in [illegible] such meteorites would first show themselves—iron, [illegible] magnesium, nickel, etc.—are not those which disting[illegible] nebular spectrum. On the contrary, this spectrum [illegible] remarkable for a few brilliant lines, very narrow and [illegible] upon a background of a faint continuous spectrum, which [illegible] n[illegible]rous bright lines, and probably some lines of absorp[illegible] [illegible] two most conspicuous lines have not been interpr[illegible] [illegible] the second line falls near, it is not coincident with [illegible] line of iron. It is hardly necessary to say that th[illegible]

position of the brightest line to the bright double line of gen, as seen in a small spectroscope in 1864, naturally ested at that early time the possibility of the presence of this ent in the nebulæ, I have been careful to point out, to prevent prehension, that in more recent years the nitrogen line and equently a lead line have been employed by me solely as ial points of reference in the spectrum.

e third line we know to be the second line of the first trum of hydrogen. Mr. Keeler has seen the first hydrogen in the red, and photographs show that this hydrogen rum is probably present in its complete form, or nearly so, e first learnt to know it in the absorption spectrum of the o stars.

e are not surprised to find associated with it the line D_3, near osition of the absent sodium lines, probably due to the atom e unknown gas, which in the sun can only show itself in the rts of highest temperature, and for this reason does not l itself by absorption in the solar spectrum.

is not unreasonable to assume that the two brightest lines, h are of the same order, are produced by substances of a lar nature, in which a vibratory motion, corresponding to a high temperature, is also necessary. These substances, as as that represented by the line D_3, may be possibly some of unknown elements which are wanting in our terrestrial nistry between hydrogen and lithium, unless, indeed, D_3 be on lighter side of hydrogen.

the laboratory we must have recourse to the electric discharge ring out the spectrum of hydrogen; but in a vacuum tube, igh the radiation may be great, from the relative fewness of luminous atoms or molecules, or from some other cause, the perature of the gas as a whole may be low.

n account of the large extent of the nebulæ a comparatively ll number of luminous molecules or atoms would probably be icient to make the nebulæ as bright as they appear to us. On h an assumption the average temperature may be low, but the ividual particles, which by their encounters are luminous, must e motions corresponding to a very high temperature, and in sense be extremely hot.

n such diffuse masses, from the great mean length of free path, encounters would be rare but correspondingly violent, and d to bring about vibrations of comparatively short period, as ears to be the case if we may judge by the great relative ghtness of the more refrangible lines of the nebular spectrum.

uch a view may perhaps reconcile the high temperature which nebular spectrum undoubtedly suggests with the much lower an temperature of the gaseous mass, which we should expect so early a stage of condensation, unless we assume a very rmous mass; or that the matter coming together had pre-usly considerable motion, or considerable molecular agitation.

The inquisitiveness of the human mind does not allow us to main content with the interpretation of the present state of the mical masses, but suggests the question—

"What see'st thou else
In the dark backward and abysm of time?"

What was the original state of things? How has it come about at by the side of ageing worlds we have nebulæ in a relatively nger stage? Have any of them received their birth from dark ns, which have collided into new life, and so belong to a second later generation of the heavenly bodies?

During the short historic period, indeed, there is no record of ch an event; still it would seem to be only through the collision dark suns, of which the number must be increasing, that a nporary rejuvenescence of the heavens is possible, and by such bings and flowings of stellar life that the inevitable end to which olution in its apparently uncompensated progress is carrying us n even for a little be delayed.

We cannot refuse to admit as possible such an origin for nebulæ. In considering, however, the formation of the existing nebulæ we ust bear in mind that in the part of the heavens within our ken e stars still in the early and middle stages of evolution exceed eatly in number those which appear to be in an advanced con-tion of condensation. Indeed, we find some stars which may be garded as not far advanced beyond the nebular condition.

It may be that the cosmical bodies which are still nebulous owe eir later development to some conditions of the part of space here they occur, such as conceivably a greater original homo-neity, in consequence of which condensation began less early other parts of space condensation may have been still further layed, or even have not yet begun. It is worthy of remark that ese nebulæ group themselves about the Milky Way, where we d a preponderance of the white-star type of stars, and almost clusively the bright-line stars which Pickering associates with e planetary nebulæ. Further, Dr. Gill concludes, from the pidity with which they impress themselves upon the plate, that e fainter stars of the Milky Way also, to a large extent, belong this early type of stars. At the same time other types of stars our also over this region, and the red hydrocarbon stars are and in certain parts; but possibly these stars may be before or hind the Milky Way, and not physically connected with it.

If light matter be suggested by the spectrum of these nebulæ, may be asked further, as a pure speculation, whether in them e are witnessing possibly a later condensation of the light matter hich had been left behind, at least in a relatively greater propor-on, after the first growth of worlds into which the heavier matter ndensed, though not without some entanglement of the lighter bstances. The wide extent and great diffuseness of this bright e nebulosity over a large part of the constellation of Orion may regarded, perhaps, as pointing in this direction. The diffuse bulous matter streaming round the Pleiades may possibly be another instance, though the character of its spectrum has not yet been ascertained. In the planetary nebulæ, as a rule, there is a sensible increase of the faint continuous spectrum, as well as a slight thickening of the bright lines towards the centre of the nebula, appearances which are in favour of the view that these bodies are condensing gaseous masses.

Prof. G. Darwin, in his investigation of the equilibrium of a rotating mass of fluid, found, in accordance with the independent researches of Poincaré, that when a portion of the central body becomes detached through increasing angular velocity, the portion should bear a far larger ratio to the remainder than is observed in the planets and satellites of the solar system, even taking into account heterogeneity from the condensation of the parent mass.

(*To be continued.*)

ADDRESS TO THE MATHEMATICAL AND PHYSICAL SECTION OF THE BRITISH ASSOCIATION.

BY PROF. OLIVER J. LODGE, D.SC., PRESIDENT OF THE SECTION.

(*Concluded from page 188.*)

In the early days of the Copernican theory, Galileo for some years refrained from teaching it, though fully believing its truth, because he considered that he had better get more fully settled in his university chair before evoking the storm of controversy which the abandonment of the Ptolemaic system would arouse. The same thing in very minor degree is going on to-day. I know of men who hesitate to avow interest in these new investigations (I do not mean credence—the time is too early for avowing credence in any but the most rudimentary and definitely ascertained facts—but hesitate to avow interest) until they have settled down more securely and made a name for themselves in other lines. Caution and slow progress are extremely necessary; fear of avowing interest or of examining into unorthodox facts is, I venture to say, not in accordance with the highest traditions of the scientific attitude.

We are, I suppose, to some extent afraid of each other, but we are still more afraid of ourselves. We have great respect for the opinions of our elders and superiors; we find the matter distasteful to them, so we are silent. We have, moreover, a righteous mistrust of our own powers and knowledge; we perceive that it is a wide region extending into several already cultivated branches of science, that a many-sided and highly-trained mind is necessary adequately to cope with all its ramifications, that in the absence of strict enquiry imposture has been rampant in some portions of it for centuries, and that unless we are preternaturally careful we may get led into quagmires if we venture on it at all.

Now let me be more definite, and try to state what this field is, the exploration of which is regarded as so dangerous. I might call it the borderland of physics and psychology. I might call it the connection between life and energy; or the connection between mind and matter. It is an intermediate region, bounded on the north by psychology, on the south by physics, on the east by physiology, and on the west by pathology and medicine. An occasional psychologist has groped down into it and become a metaphysician. An occasional physicist has wandered up into it and lost his base, to the horror of his quondam brethren. Biologists mostly look at it askance, or deny its existence. A few medical practitioners, after long maintenance of a similar attitude, have begun to annex a portion of its western frontier. The whole region seems to be inhabited mainly by savages, many of them, so far as we can judge from a distance, given to gross superstition. It may, for all I know, have been hastily traversed and rudely surveyed by a few clear-eyed travellers; but their legends concerning it are not very credible, certainly are not believed.

Why not leave it to the metaphysicians? I say it has been left to them along enough. They have explored it with insufficient equipment. The physical knowledge of the great philosophers has been necessarily scanty. Men of genius they were, and their writings may, when interpreted, mean much. But to us, as physicists, they are unsatisfactory; their methods are not our methods. They may be said to have floated a balloon over the region with a looking-glass attached, in which they have caught queer and fragmentary glimpses. They may have seen more than we give them credit for, but they appear to have guessed far more than they saw.

Our method is different. We prefer to creep slowly from our base of physical knowledge, to engineer carefully as we go, establishing forts, making roads, and thoroughly exploring the country; making a progress very slow, but very lasting. The psychologists from their side may meet us. I hope they will; but one or other of us ought to begin.

A vulnerable spot on our side seems to be the connection between life and energy. The conservation of energy has been so long established as to have become a commonplace. The relation of life to energy is not understood. Life is not energy, and the death of an animal affects the amount of energy no whit; yet a live animal exerts control over energy which a dead one cannot. Life is a guiding or directing principle, disturbing to the physical world, but not yet given a place in the scheme of physics. The transfer of energy is accounted for by the performance of work; the guidance of energy needs no work, but demands force only. What is force? and how can living beings exert it in the way they do? As automata, worked by preceding conditions—that is, by the past—say the materialists? Are we so sure that they are not worked by the future, too? In other words, that the totality of things, by which everyone must admit that actions are guided, includes the future as well as the past, and that to attempt to

deduce those actions from the past only will prove impossible.* In some way matter can be moved, guided, disturbed by the agency of living beings; in some way there is a control, a directing agency active, and events are caused as its choice and will that would otherwise not happen.

A luminous and helpful idea is that *time* is but a relative mode of regarding things; we progress through phenomena at a certain definite pace, and this subjective advance we interpret in an objective manner, as if events necessarily happened in this order and at this precise rate. But that may be only one mode of regarding them. The event may be in some sense existent always, both past and future, and it may be we who are arriving at them, not they which are happening. The analogy of a traveller in a railway train is useful. If he could never leave the train nor alter its pace, he would probably consider the landscapes as necessarily successive, and be unable to conceive their co-existence.

The analogy of a solid cut into sections is closer. We recognise the universe in sections, and each section we call the present. It is like the string of slices cut by a microtome; it is our way of studying the whole. But we may err in supposing that the body only exists in the slices which pass before our microscope in regular order and succession.

We perceive, therefore, a possible fourth dimensional aspect about time, the inexorableness of whose flow may be a natural part of our present limitations. And if once we grasp the idea that past and future may be actually existing, we can recognise that they may have a controlling influence on all present action, and the two together may constitute "the higher plane," or the totality of things, after which, as it seems to me, we are impelled to seek, in connection with the directing of force or determinism, and the action of living beings consciously directed to a definite and preconceived end.

Inanimate matter is controlled by the *vis à tergo*; it is operated on solely by the past.† Given certain conditions, and the effect in due time follows. Attempts have been made to apply the same principle to living and conscious beings, but without much success. These seem to work for an object, even if it be the mere seeking for food; they are controlled by the idea of something not yet palpable. Given certain conditions, and their action cannot certainly be predicted; they have a sense of option and free will. Either their actions are really arbitrary and indeterminate, which is highly improbable, or they are controlled by the future as well as by the past. Imagine beings thus controlled: automata you may still call them, but they will be living automata, and will exhibit all the characteristics of live creatures. Moreover, if they have a merely experiential knowledge, necessarily limited by memory and bounded by the past, they will be unable to predict each other's actions with any certainty, because the whole of the data are not before them. May not a clearer apprehension of the meaning of life, and will, and determinism be gradually reached in some such direction as this?

By what means is force exerted, and what, definitely, is force? I can hardly put the question here and now so as to be intelligible, except to those who have approached and thought over the same difficulties; but I venture to say that there is here something not provided for in the orthodox scheme of physics; that modern physics is not complete, and that a line of possible advance lies in this direction.

I might go farther. Given that force can be exerted by an act of will, do we understand the mechanism by which this is done? And if there is a gap in our knowledge between the conscious idea of a motion and the liberation of muscular energy needed to accomplish it, how do we know that a body may not be moved without ordinary material contact by an act of will? I have no evidence that such a thing is possible. I have tried once or twice to observe its asserted occurrence, and failed to get anything that satisfied me. Others may have been more fortunate. In any case, I hold that we require more knowledge before we can deny the possibility. If the conservation of energy were upset by the process, we should have grounds for denying it; but nothing that we know is upset by the discovery of a novel medium of communication, perhaps some more immediate action through the ether. It is no use theorising; it is unwise to decline to examine phenomena because we feel too sure of their impossibility. We ought to know the universe very thoroughly and completely before we take up that attitude.

Again, it is familiar that a thought may be excited in the brain of another person, transferred thither from our brain, by pulling a suitable trigger; by liberating energy in the form of sound, for instance, or by the mechanical act of writing, or in other ways. A pre-arranged code called language, and a material medium of communication, are the recognised methods. May there not also be an immaterial (perhaps an ethereal) medium of communication? Is it possible that an idea can be transferred from one person to another by a process such as we have not yet grown accustomed to, and know practically nothing about? In this case I have evidence. I assert that I have seen it done, and am perfectly convinced of the fact. Many others are satisfied of the truth of it too. Why must we speak of it with bated breath, as of a thing of which we are ashamed? What right have we to be ashamed of a truth?

And after all, when we have grown accustomed to it, it will not seem altogether strange. It is, perhaps, a natural consequence of the community of life or family relationship running through all living beings. The transmission of life may be likened in some ways to the transmission of magnetism, and all magnets are sympathetically connected, so that if suitably suspended a vibration from one disturbs others, even though they be distant ninety-two million miles.

It is sometimes objected that, granting thought-transference or telepathy to be a fact, it belongs more especially to lower forms of life and that as the cerebral hemispheres develop we become independent of it; that what we notice is the relic of a decaying faculty, not the germ of a new and fruitful sense; and that progress is not to be made by studying or attending to it. It may be that it is an immature mode of communication, adapted to lower stages of consciousness than ours, but how much can we not learn by studying immature stages? As well might the objection be urged against a study of embryology. It may, on the other hand, be an indication of a higher mode of communication, which shall survive our temporary connection with ordinary matter.

I have spoken of the apparently direct action of mind on mind, and of a possible action of mind on matter. But the whole region is unexplored territory, and it is conceivable that matter may react on mind in a way we can at present only dimly imagine. In fact, the barrier between the two may gradually melt away, as so many other barriers have done, and we may end in a wider perception of the unity of Nature, such as philosophers have already dreamt of.

I care not what the end may be. I do care that the enquiry shall be conducted by us, and that we shall be free from the disgrace of jogging along accustomed roads, leaving to outsiders the work, the ridicule, and the gratification of unfolding a new region to unwilling eyes.

It may be held that such investigations are not physical, and do not concern us. We cannot tell without trying. In that I trust my instinct. I believe there is something in this region which does concern us as physicists. It may concern other sciences too. It must, one would suppose, some day concern biology; but with that I have nothing to do. Biologists have their region, we have ours, and there is no need for us to hang back from an investigation because they do. Our own science, of physics or natural philosophy in its widest sense, is the king of the sciences, and it is for us to lead, not to follow.

And I say, have faith in the intelligibility of the universe. Intelligibility has been the great creed in the strength of which all intellectual advance has been attempted, and all scientific progress made.

At first things always look mysterious. A comet, lightning, the aurora, the rainbow—all strange anomalous mysterious apparitions. But scrutinised in the dry light of science, their relationship with other better known things becomes apparent. They cease to be anomalous; and though a certain mystery necessarily remains, it is no more a property peculiar to them: it is shared by the commonest objects of daily life.

The operations of a chemist, again, if conducted in a haphazard manner, would be an indescribable medley of effervescences, precipitations, changes in colour and in substance; but, guided by a thread of theory running through them, the processes fall into a series, they all become fairly intelligible, and any explosion or catastrophe that may occur is capable of explanation too.

Now I say that the doctrine of ultimate intelligibility should be pressed into other departments also. At present we hang back from whole regions of enquiry and say they are not for us. A few we are beginning to grapple with. The nature of disease is yielding to scrutiny with fruitful result; the mental aberrations and abnormalties of hypnotism, duplex personality, and allied phenomena, are now at last being taken under the wing of science after long ridicule and contempt. The phenomenon of crime, the scientific meaning and justification of altruism, and other matters relating to life and conduct, are beginning, or perhaps are barely yet beginning, to show a vulnerable front over which the forces of science may pour.

Facts so strange that they have often been called miraculous are now no longer regarded as entirely incredible. All occurrences seem reasonable when contemplated from the right point of view, and some are believed in which in their essence are still quite marvellous. Apply warmth for a given period to a sparrow's egg, and what result could be more incredible or magical if now discovered for the first time? The possibilities of the universe are as infinite as is its physical extent. Why should we grope with our eyes always downward, and deny the possibility of everything out of our accustomed beat?

If there is a puzzle about free will, let it be attacked; puzzles mean a state of half knowledge. By the time we can grasp something more approximating to the totality of things the paradoxity of paradoxes drops away and becomes unrecognisable. I seem to myself to catch glimpses of clues to many of these old questions, and I urge that we should trust consciousness, which has led us thus far; should shrink from no problem when the time seems ripe for an attack upon it, and should not hesitate to press investigation, and ascertain the laws of even the most recondite problems of life and mind.

What we know is as nothing to that which remains to be known. This is sometimes said as a truism; sometimes it is half doubted. To me it seems the most literal truth, and that if we narrow our view to already half-conquered territory only, we shall be false to the men who won our freedom, and treasonable to the highest claims of science.

I must now return to the work of this section, from which I have apparently wandered rather far afield, further than is customary—perhaps further than is desirable. But I hold that occasionally a

* The expression "controlled by the future," I first heard in a conversation with G. F. Fitzgerald, who seemed to consider it applicable to all events, without exception.

† This is, of course, not assertion but suggestion. It may be erroneous to draw any such distinction between animate and inanimate.

wide outlook is wholesome, and that without such occasional survey the rigid attention to detail and minute scrutiny of every little fact which are so entirely admirable and are so rightly here fostered, are apt to become unhealthily dull and monotonous. Our life-work is concerned with the rigid framework of facts, the skeleton or outline map of the universe; and, though it is well for us occasionally to remember that the texture and colour and beauty which we habitually ignore are not therefore in the slightest degree non-existent, yet it is safest speedily to return to our base and continue the slow and laborious march with which we are familiar and which experience has justified. It is because I imagine that such systematic advance is now beginning to be possible in a fresh and unexpected direction that I have attempted to direct your attention to a subject which, if my prognostications are correct, may turn out to be one of special and peculiar interest to humanity.

THE LONDON-PARIS TELEPHONE.*

BY W. H. PREECE, F.R.S.

1. I have already on two occasions, at Newcastle and at Leeds, brought this subject before Section G, and have given the details of the length and construction of the proposed circuit. I have now to report not only that the line has been constructed and opened to the public, but that its success, telephonic and commercial, has exceeded the most sanguine anticipations. Speech has been maintained with perfect clearness and accuracy. The line has proved to be much better than it ought to have been, and the purpose of this paper is to show the reason why.

The lengths of the different sections of the circuit are as follows:

London to St. Margaret's Bay	84·5	miles.
St. Margaret's Bay to Sangatte (cable)	23·	,,
Sangatte to Paris	199·	,,
Paris underground	4·8	,,
Total	311·3	,,

The resistances are as follows:

Paris underground	70	ohms.
French line	294	,,
Cable	143	,,
English line	183	,,
Total (R)	693	,,

The capacities are as follows:

Paris underground	0·43	microfarads.
French line	3·33	,,
Cable	5·52	,,
English line	1·32	,,
Total (K)	10·62	,,

$$693 \times 10{\cdot}62 = 7{,}359 = K\,R,$$

a product which indicates that speech should be very good.

2. *Trials of Apparatus.*—The preliminary trials were made during the month of March between the chief telegraph offices of the two capitals, and the following microphone transmitters were compared:

Ader	Pencil form.
Berliner	Granular ,,
D'Arsonval	Pencil ,,
De Jongh	,, ,,
Gower-Bell	,, ,,
Post Office switch instrument	Granules and lamp filaments.
Roulez	Lamp filaments.
Turnbull	Pencil form.
Western Electric	Granular.

The receivers consisted of the latest form of double-pole Bell telephones with some Ader and D'Arsonval receivers for comparison. After repeated trials it was finally decided that the Ader, D'Arsonval, Gower-Bell (with double-pole receivers instead of tubes), Roulez, and Western Electric were the best, and were approximately equal.

These instruments were, therefore, selected for the further experiments, which consisted of using local extensions in Paris and London. The wires were in the first instance extended at the Paris end to the Observatory through an exchange at the Avenue des Gobelines. The length of this local line is 7 kms. The wires are guttapercha covered, placed underground, and not suitable for giving the best results.

The results were, however, fairly satisfactory. The wires were extended to the Treasury in London by means of the ordinary underground system. The distance is about two miles, and although the volume of sound and clearness of articulation were perceptibly reduced by these additions to the circuit, conversation was quite practicable.

Further trials were also made from the Avenue des Gobelines on underground wires of five kilometres long, and also with some renters in Paris with fairly satisfactory results. The selected telephones were equally efficient in all cases, which proves that to maintain easy conversation when the trunk wires are extended to local points it is only necessary that the local lines shall be of a standard not lower than that of the trunk line. The experiments also confirm the conclusion that long-distance speaking is solely a question of the circuit and its environments, and not one of apparatus. The instruments finally selected for actual work were Gower-Bell for London and Roulez for Paris.

3. The results are certainly most satisfactory. There is no circuit in or out of London on which speech is more perfect than it is between London and Paris. In fact, it is better than I anticipated, and better than calculation led me to expect. Speech has been possible not only to Paris but through Paris to Bruxelles, and even, with difficulty, through Paris to Marseilles, a distance of over 900 miles. The wires between Paris and Marseilles are massive copper wires specially erected for telephone business between those important places.

4. *Business Done.*—The charge for a conversation between London and Paris is 8s. for three minutes' complete use of the wire. The demand for the wire is very considerable. The average number of talks per day, exclusive of Sunday, is 86. The maximum has been 108. We have had as many calls as 19 per hour—the average is 15 during the busy hours of the day. As an instance of what can be done 150 words per minute have been dictated in Paris and transcribed in London by shorthand writing. Thus in three minutes 450 words were recorded, which at 8s. cost five words for a penny.

5. *Difficulties.* — The difficulties met with in long-distance speaking are several, and they may be divided into (*a*) those due to external disturbances and (*b*) those due to internal opposition.

(*a.*) Every current rising and falling in the neighbourhood of a telephone line within a region, say, of 100 yards, whether the wire conveying it be underground or overground, induces in the telephone circuit another current, producing in the telephone a sound which disturbs speech, and if the neighbouring wires are numerous and busy, as they are on our roads and railways, these sounds become confusing, noisy, and ultimately entirely preventative of speech. This disturbance is, however, completely removed by forming the telephone circuit of two wires placed as near to each other as possible, and twisted around each other without touching, so as to maintain the mean average distance of each wire from surrounding conductors the same everywhere. Thus similar currents are induced in each of the two wires, but being opposite in direction, as far as the circuit is concerned, they neutralise each other, and the circuit, therefore, becomes quite silent.

In England we make the two wires revolve completely round each other in every four poles, but in France it is done in every six poles. The reason for the change is the fact that in the English plan the actual crossing of the wires takes place in the span between the poles, while in the French plan it takes place at the poles. This is supposed to reduce the liability of the wires to be thrown into contact with each other by the wind, but, on the other hand, it diminishes the geometrical symmetry of the wires—so very essential to ensure silence. As a matter of fact, contacts do not occur on well-constructed lines, and I think our English wires, being more symmetrical, are freer from external disturbance than those in France.

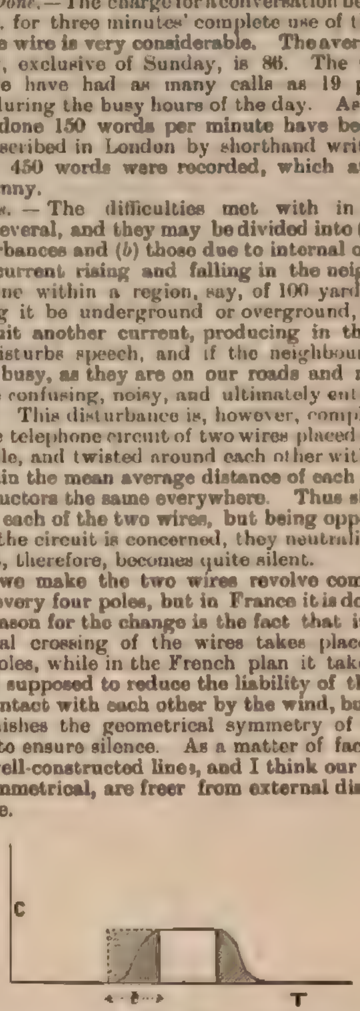

FIG. 1.

(*b.*) The internal opposition arises from the resistance, R, the capacity, K, and the electromagnetic inertia, L, of the circuit. A current of electricity takes time to rise to its maximum strength and time to fall back again to zero. Every circuit has what is called its time constant, *t*, Fig. 1, which regulates the number of current waves which can be transmitted through it per second. This is the time the current takes to rise from zero to its working maximum and the time it takes to fall from this maximum to zero again, shown by the shaded portions of the figure; the duration of the working current being immaterial and shown by the unshaded portion. The most rapid form of quick telegraphy requires about 150 currents per second, currents each of which must rise and fall in $\frac{1}{150}$th of a second, but for ordinary telephone speaking we must have about 1,500 currents per second, or the time which each current rises from zero to its maximum intensity must not exceed $\frac{1}{3000}$th part of a second. The time constant of a telephone circuit should therefore not be less than ·0003 second.

Resistance alone does not affect the time constant. It diminishes the intensity or strength of the currents only; but resistance, combined with electromagnetic inertia and with capacity, has a serious retarding effect on the rate of rise and fall of the currents. They increase the time constant and introduce a slowness which may be called retardance, for they diminish the rate at which currents can be transmitted. Now the retardance due to electromagnetic inertia increases directly with the amount of electromagnetic inertia present, but it diminishes with the amount of resistance of the conductor. It is expressed by the ratio $\frac{L}{R}$ while that due to capacity increases directly, both with the capacity and with the resistance, and it is expressed by the product, K R. The whole retardance, and, therefore, the speed of working the circuit or the clearness of speech, is given by the equation

$$\frac{L}{R} + K\,R = t$$

or

$$L + K\,R^2 = R\,t.$$

* Paper read before the British Association.

ow in telegraphy we are not able altogether to eliminate L, but we can counteract it, and if we can make $R\,t = 0$, then

$$L = -K R^2,$$

which is the principle of the shunted condenser that has been introduced with such signal success in our Post Office service, and has virtually doubled the carrying capacity of our wires.

If, in the above equation, we make $L = 0$

$$K R = t.$$

This is done in telephony, and hence we obtain the law of retardance, or the law by which we can calculate the distance to which speech is possible. All my calculations for the London and Paris line were based on this law, which experience has shown it to be true.

How is electromagnetic inertia practically eliminated? First, by the use of two massive copper wires, and secondly by symmetrically revolving them around each other. Now L depends on the geometry of the circuit, that is, on the relative form and position of the different parts of the circuit, which is invariable for the same circuit, and is represent by a coefficient, λ. It depends also on the magnetic qualities of the conductors employed and of the space embraced by the circuit. This specific magnetic capacity is a variable quantity, and is indicated by μ for the conductor and by μ_0 for air. It depends also on the rate at which currents rise and fall, and this is indicated by the differential coefficient $\frac{dC}{dt}$. It depends finally on the number of lines of force due to its own current which cut the conductor in the proper direction; this is indicated by β. Combining these together we can represent the electromagnetic inertia of a metallic telephone circuit as

$$L = \lambda\,(\mu + \mu_0)\,\frac{dC}{dt} \times \beta.$$

Now, $\lambda = 2 \log \frac{d^2}{a^2}$. Hence the smaller we make the distance, d, between the wires, and the greater we make their diameter, a, the smaller becomes λ. It is customary to call the value of μ for air, and copper, 1, but this is purely artificial and certainly not true. It must be very much less than one in every medium, excepting the magnetic metals, so much so that in copper it may be neglected altogether, while in the air it does not matter what it is, for by the method of twisting one conductor round the other, the

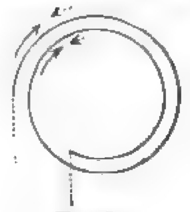

Fig. 2.

magnetisation of the air space by the one current of the circuit rotating in one direction is exactly neutralised by that of the other element of the circuit rotating in the opposite direction. Now, β, in two parallel conductors conveying currents of the same sense, that is flowing in the same direction, is retarding, Fig. 2, and is therefore a positive quantity, but when the currents flow in opposite directions, as in a metallic loop, Fig. 3, they tend to assist each other and are of a negative character. Hence in a metallic telephone circuit we may neglect L *in toto* as I have done.

I have never yet succeeded in tracing any evidence of electromagnetic inertia in long single copper wires, while in iron wires the value of L may certainly be taken at ·005 henry per mile.

Fig. 3.

In short metallic circuits, say of lengths up to 100 miles, this negative quantity does not appear, but in the Paris-London circuit this helpful mutual action of opposite currents comes on in a peculiar way. The presence of the cable introduces a large capacity practically in the centre of the circuit. The result is that we have in each branch of the circuit between the transmitter, say, at London and the cable at Dover, extra currents at the

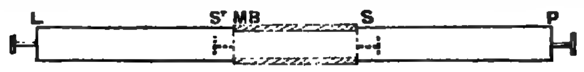

Fig. 4.

commencement of the operation, which, flowing in opposite directions, mutually react on each other, and practically prepare the way for the working currents. The presence of these currents is proved by the fact that when the cable is disconnected at Calais, as shown in Fig. 5, and telephones are inserted in series, as shown at D and D', speech is as perfect between London and St. Margaret's Bay as if the wires were connected across, or as if the circuit were through to Paris. Their effect is precisely the same as though the capacity of the aerial section were reduced by a quantity, M, which is of the same dimension or character as K. Hence the retardance equation becomes

$$R\,(K - M) = t.$$

Thus it happens that the London-Paris telephone works better than was expected. The nature of M is probably equivalent to about ·0075 ϕ per mile, and therefore K should be also about ·0075 ϕ instead of ·0156 ϕ per mile. This helpful action of mutual induction is present in all long circuits, and it is the reason why we were able to speak to Brussels and even to Marseilles. It appears in every metallic loop, and vitiates the measurement of electromagnetic inertia and of capacity of loops. Thus, if we measure the capacity of a loop as compared with a single wire, the amount per mile may be 50 per cent. greater than it ought to be, while if we measure the capacity of one branch of a circuit under the conditions of the London-Paris telephone line, it may be 50 per cent. less than it ought to be. This effect of M is shown by the dotted line in Fig. 1.

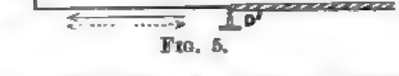

Fig. 5.

Telephonic currents—that is, currents induced in the secondary wire of an induction coil due to the variation of microphonic currents in the primary wire—are not alternating currents. They do not follow the constant periodic law, and they are not true harmonic sine functions of the time. The microphonic currents are intermittent or pulsatory, and always flow in the same direction. The secondary currents are also always of the same sign, as are the currents in a Ruhmkorff coil, and as are the currents in high vacua with which Crookes has made us so familiar. Moreover, the frequency of these currents is a very variable quantity, not only due to the various tones of voices, but to the various styles of articulation. Hence the laws of periodic alternate currents following the sine function of the time fail when we come to consider microphones and telephones. It is important to bear this in mind, for nearly everything that has hitherto been written on the subject assumes that telegraphic currents follow this periodic sine law. The currents derived from Bell's original magneto-transmitters are alternate, and comply more nearly with the law. The difference between them and microphones is at once perceptible. Muffling and disturbance due to the presence of electromagnetic inertia become evident, which are absent with microphones. I tested this between London and St. Margaret's, and found the effect most marked.

7. *Lightning.*—A metallic telephone circuit may have a static charge induced upon it by a thunder cloud, as shown in Fig. 6. Such a charge is an electric strain which is released when the charged cloud flashes into the earth or into a neighbouring cloud. If there be electromagnetic inertia present, the charge will surge backward and forward through the circuit until it dies out. If there be no E.M.F. present it will cease suddenly, and neutrality will be attained at once. Telephone circuits indicate this operation by peculiar and characteristic sounds. An iron wire circuit

Fig. 6.

produces a long swish or loud sigh, but a copper wire circuit like the Paris-London telephone emits a short, sharp report, like the crack of a pistol, which is sometimes startling, and has created fear, but there is no danger or liability to shock. Indeed, the start has more than once thrown the listener off his stool, and has led to the belief that he was knocked down by lightning.

8. The future of telephone working, especially in large cities, is one of underground wires, and the way to get over the difficulties of this kind of work is perfectly clear. We must have metallic circuits, twisted wires, low resistance, and low capacity. In Paris a remarkable cable, made by Fortin-Herman, gives an exceedingly low capacity—viz., only ·069 ϕ per mile. In the United States they are using a wire insulated with paper which gives ·08 ϕ per mile. We are using in London Fowler-Waring cable giving a capacity of 1·8 ϕ per mile, the capacity of gutta-covered wire being 3 ϕ per mile.

THE MEASUREMENT OF LIQUID RESISTANCES.*

BY J. SWINBURNE.

The great difficulties in measuring liquid resistances arise from polarisation at the electrodes. Various methods of eliminating the errors arising from polarisation, and from variations of surface resistance due to bubbles, have come into use; the most usual being to employ an alternating current and a telephone.

The following are some methods of avoiding polarisation errors in a manner analogous to that employed by Sir William Thomson, Mr. Heaviside, and others, in measuring low resistances. In

* Paper read before the British Assocition.

within one or two in a million. After standing for nearly three weeks they were marked all over, and varied nearly a tenth per cent. among themselves, and more than that compared with 1,621, which had been in another solution acting as a standard in other experiments.

From this it appears that in order to give good results the zincs should be heavily amalgamated. If thoroughly amalgamated, practically any zinc will do. The zincs which gave low E.M.F.'s were always the small ones—that is to say, those which would get the thickest coatings of iron.

To find out whether amalgamating altered the readings, an amalgam was made by touching mercury with zinc. It was more than ½ per cent. wrong. After dissolving more zinc, the reading was still low, though by stirring in zinc it soon came up to 0·9984 and 0·9994. A series of amalgams was made containing 25, 12½, 5, 2½, and 1 per cent. of zinc and one with less zinc. These were put in solution 1,628 of zinc sulphate with little iron. The solution was poured in and out many times to secure homogeneity, an important matter, to which I will return. The readings obtained were—

25 per cent.	1·000025	and	0·99999
12½ ,,	1·00008	,,	1·000000
5 ,,	1·000035	,,	1·000010
2½ ,,	1·00005	,,	1·000020
1 ,,	0·997225		
trace below 0·995			

The second readings, which were taken a few minutes later, are close enough. Amalgams therefore having some 2½ per cent. of zinc will do. Lord Rayleigh has done a great deal of work on amalgam cells, and he found the amalgam always cracked the tube. I made one H cell with amalgam in 1888 which had the platinum led out at the bottom, but it did not crack. I made several other cells at the same time with an internal test tube to hold the amalgam, and none of them cracked. On the other hand, the 5 per cent. amalgam broke its test tube. I would suggest that platinum sealed to German glass is always left under constraint, and the crystallisation of the zinc also adds pressure which cracks the tube. My H cell had a little lead glass just round the platinum ; moreover, it was very small. The 2½ per cent. amalgam is liquid, so there is no danger from it.

To sum up as to the zinc, then, I would suggest that if rod be used it should be well amalgamated first. It is gradually amalgamated in the cell, but this process is slow, especially if the solution contains basic zinc sulphate. The gradual amalgamation is probably one process that makes many cells take a few weeks to arrive at final values. If zinc rod is used, it would seem better to use platinum, silver, or zinc wire to make connection, and to avoid solder, otherwise it is only a matter of time till the zinc falls off. All these troubles are swept away by the use of zinc amalgam, as proposed by Lord Rayleigh. There is another reason in its favour to be mentioned under the head of temperature coefficients.

The Zinc Sulphate Solution.

The chief difficulty arises from the presence of iron. Samples were bought from Messrs. Hopkin and Williams and Becker. These both contained iron. Iron is often to be seen as a deposit after shaking up with zinc carbonate. Some sulphate of zinc was made by dissolving "pure" zinc in redistilled sulphuric acid. Provided there is always excess of zinc, one would expect little iron. Another batch was made by leaving excess of commercial granulated zinc in dilute commercial acid, which itself contains iron. Neither of these had enough iron to blacken zinc. None of the samples of zinc sulphate blackened copper. When I say that samples of sulphate of zinc bought as pure from such people as Messrs. Hopkin and Williams contain iron, I mean that they contain enough to cause variations in cells, not enough to get precipitates of Prussian blue. Zinc or barium carbonate might be expected to precipitate all the iron. It does not, however. Probably carbonate of iron really exists and remains in solution. In experiments on alkaline secondary cells with iron plates, I produced a green compound which appeared to be a real carbonate of iron. The best method of dealing with iron is to acknowledge its presence and amalgamate the zincs. The best zinc sulphate solutions I used were obtained by dissolving granulated zinc in dilute commercial acid, keeping the zinc in excess. Solution 1,628, already mentioned, was made this way. Of course, pure zinc and acid may be used. This method produces basic sulphate, too, especially if hot. This can be afterwards neutralised by acid.

It is usual to shake up zinc sulphate with "carbonate," and to filter before use. This is probably because the sulphate reddens litmus paper. Neutral zinc sulphate reddens litmus paper, however, so there seems little reason for adding zinc "carbonate." I imagine that any salt which can give up a little acid by forming a basic salt, will redden litmus. The sulphate can be neutralised by being left in contact with zinc. A solution that is strongly alkaline to methyl orange reddens litmus paper. What is bought as zinc "carbonate," is either a basic carbonate or a mixture containing oxide. There are some half-dozen basic sulphates of zinc, and shaking up with "carbonate" forms some of these. The presence of basic sulphate in the solution prevents the mercury salt getting to the zinc to amalgamate it. Mercurous sulphate is, I believe, split up by water into basic and acid mercurous sulphate. Basic zinc sulphate precipitates any normal mercurous sulphate that may be dissolved, and the acid sulphate as basic mercurous sulphate or as mercurous oxide. This accounts for the dark grey deposit often seen on the top of the paste in cells prepared in the usual way. The mercury salt thus cannot get to the zinc till the whole of the basic zinc salt has been used up.

In order to test the effects of various solutions of zinc sulphate test tubes with feet were filled with the solutions, and were connected with the standard solution by a syphon tube. This had one end blocked with filter paper to prevent mixture of solutions. It is needless to give tables of readings. Anomalous results were obtained at first, but they were all traceable to the zincs. After amalgamation, all the saturated solutions gave the same reading within a few in a million. 1,621, made by dissolving pure zinc in acid, was 100 in a million too low.

To test the effect of acid, I added a few drops of "normal"—that is, very dilute sulphuric acid—to a saturated solution of Hopkin and Williams's zinc sulphate. The solution was then strongly acid to methyl orange. The solution read 1·001200 against the 1,621 in some more of the same solution. On neutralising with zinc carbonate, the reading was 1·001100. Free acid appears to make little difference. This experiment was repeated with new solutions. The two zincs were first tested in the same solution. One gave about eight in a million ; this was moved into the other tube, B, of the same solution and taken as a standard. The reading was now 1·000110 for A. Five drops of pure acid were put in a small test tube, and a little of A added, and the tube cooled. Then the acid was added to A, which became strongly acid to methyl orange. The reading was now 1·000000. The liquid was then shaken up with zinc carbonate till alkaline to orange, and the reading rose to 1·0009. On the other hand, a solution which had been left in contact with excess of zinc carbonate for some weeks gave no deflection. In any case, the zinc will eventually use up any free acid. These anomalous results may be partly due to slight differences of density in the solutions, and partly to unascertained causes.

This is the last point that need be mentioned in connection with the solution. The solubility of zinc sulphate varies enormously with the temperature. If a tube of it is left with crystals at the bottom, when it comes to a low temperature all the crystals collect at the foot. When the temperature rises, the upper part can only become saturated again slowly by diffusion. To test this, two zincs were put in a test tube of saturated solution with crystals at the bottom. After a few days the top zinc gave 1·0005 compared with the bottom. The lower zinc was then raised, reading 1. The other zinc was then depressed, reading 0·999475. The difference of density thus causes an error of 5 in 10,000. This tube was some 10 centimetres long, so the error in standard cells may not be so great as this, still, diffusion is very slow even in a short cell. This also influences the temperature coefficient. The question of super-saturation has already been dealt with so thoroughly by Lord Rayleigh that I saw no use in experimenting on it. There are some half dozen hydrates and an anhydrous sulphate of zinc. If the solution is not heated above blood heat, the $Zn\,SO_4\,7H_2O$ crystallises out.

To sum up : the chief errors caused by the solution are due to traces of iron and variations of density. The zinc should therefore be amalgamated. I would suggest that zinc carbonate be omitted. To avoid changes of density, if a saturated solution is imperative, a zinc amalgam must be employed with crystals lying on its surface. This can be done in one of Lord Rayleigh's H cells, or a smaller tube can be slipped into the cell. The surfaces must be on the same level, else all the crystals will collect on the lower one, as that lowers the centre of gravity of the system, thus doing work. A small test tube full of crystals was put inside a larger tube of saturated solution, and this action was found actually to take place.

There is some further complication between the zinc and its solution. Even amalgams will give very large variations if moved about in the solution. This is the case even with dilute solutions. I can scarcely hazard a suggestion. Some Lippmann effect may be produced by shaking the amalgam. This does not seem at all likely. It is possible that zinc, even when amalgamated, will dissolve in sulphate, forming basic sulphate, provided the zinc is moved so that the hydrogen can get away in solution, as it cannot come off in bubbles. Ordinary zinc will dissolve in boiling zinc sulphate solution, the solution turning milky on cooling ; but I cannot make out whether amalgamated zinc does or not. In the cold it gives off bubbles slowly. I do not know whether any surface boundary layers can cause such effects ; whether there is an action like a frictional electric machine going on.

Mercurous Sulphate.

Samples of mercurous sulphate were bought from Messrs. Becker and Hopkin and Williams. I also had some samples from Hopkin and Williams, Becker and Griffin, bought in 1888, and some I made myself at the same time. I also prepared some new specimens by heating in an oven a flask with mercury twice distilled in vacuo and redistilled acid. The temperature was kept at 125deg. C. by a mercury regulator, and only a portion of the mercury was dissolved. The sulphate was washed with distilled water and dried. It is in white crystals.

Other samples were made by dissolving mercurous nitrate in water slightly acidified with nitric acid, and precipitating with zinc sulphate. This is perfectly white unless much washed. A yellow colour then appears.

There are several sulphates of mercury. There is mercuric sulphate, which, on shaking up with water, splits into acid mercuric sulphate, which is soluble, and basic mercuric sulphate, which is a bright yellow insoluble powder. There is, I believe, a mercuric-mercurous sulphalte. I do not know it, nor do I know if there are acid and basic salts to correspond. There is also mercurous sulphate, which some say is soluble in water, but which, I believe, splits up into acid mercurous sulphate, which is slightly soluble, and basic mercurous sulphate, which is a dirty yellow powder. In testing the pastes, some of that used for the

cells was used as a standard. Zinc No. 1,621 was kept in on of sulphate, and was connected by a syphon with the tube dard paste, the cell thus made being checked against the standard. After a few days there was never any deflec- The pastes could not be measured so easily as zincs or ns on account of their high resistance. There is also at trouble from want of contact with the platinum wires. heating these and dipping in mercury is not always . I found it better to bend the platinum into an eye and it in mercury, and not to consider it amalgamated till it p a film of mercury with it, or to use sodium amalgam. The tube was no longer stopped with filter paper, so its resist- as lower. Some of the experiments on pastes are given following table:

) was B.O.T. paste. Its readings are given in terms of the B.O.T. standard. The other pastes are given in terms 0. Columns one, two, and three are not corrected for the on of 1,650, as from the readings of 1,653, 1,654, and 1,654, as if the B.O.T. cell had been varying owing to alterations ity of the zinc sulphate solution.

1.—Paste given to me by Mr. Fox Bourne. The bottle had 's label, but the paste was grey like that of Hopkin and ns, from whom Mr. Fox Bourne had also bought sulphate. always far too high.

2.—Paste of basic mercuric sulphate. This was always very This goes to show that basic mercuric sulphate is harmless, mercuric sulphate may perhaps be rendered harmless by g it thoroughly.

3.—Paste made by dissolving mercury as already described. in low, gradually coming to be too high on shaking.

4.—Paste made by precipitating mercurous nitrate with zinc te. This is quite white unless copiously washed, then it is y yellow owing to the presence of basic protosulphate. ater containing chalk must not be used for washing. This contains no mercuric salts. To test the pastes for mercuric they were shaken with water and the solution precipitated alt and filtered. The filtrate was tested with hydrogen le and with potassium iodide. This paste seem right.

5.—Paste bought in 1891 from Becker. This was a white , and remained white as paste. Contained no persalt. ally fell to normal. The pastes nearly always give high s after stirring up well.

6.—Paste from Hopkin and Williams, 1891. Powder, grey, g yellowish in the paste, contains a good deal of persalt. s the paste generally used for cells. Two other specimens from the same firm some years ago also contained persul- The paste begins very high, gradually falling. Washing e persulphate may help this. I do not know if sodium e could be used to reduce the persalt.

7.—Paste from Griffin. Grey powder. Contains a great f persalt. On July 24th, 1891, excess of zinc carbonate was to this paste It frothed up and remained as a sort of . The reading then fell gradually till it was too low.

8.—Paste made by slow electrolysis. M Potier has proposed made by using a mercury anode and cathode in zinc te; but I have not the reference. The zinc amalgam is, of too weak unless a great deal of electricity is passed h. The paste formed is the yellow basic mercurous te. The reading was too high first, and fell to nearly . Finally a little acid was added on August 2nd, 1891, e reading was very high. I made other unsuccessful nents on Potier cells.

2.—H cell with 2½ per cent. amalgam. It was always low, ly because its solution was saturated at both poles. Of as this was a complete cell, it was compared direct with O.T. cell, and as the temperature coefficients are different, there are other causes of variation, it is impossible to say was at fault. Readings like those of 1,654 may be got with but not with different kinds of cell.

4.—Becker paste, 1888, with zinc carbonate.

5.—Same without carbonate. Probably there was not carbonate to convert the whole of the sulphate into basic Lord Rayleigh recommends the addition of a very small ty of zinc carbonate to the paste. If the paste has persul- the carbonate will first convert it into basic persulphate, appears to be harmless. An excess of zinc carbonate will, se, waste the mercurous sulphate.

3.—Complete cell with Becker paste; put in dry.

1.—H cell. Becker paste.

2.—Paste made by electrolysis in acid solution.

3.—Tube cell, with precipitated mercurous sulphate, made .

ill be seen that the cells seem to tend towards a common but that is almost all that can be said.

Board of Trade circular directs the paste to be rubbed up mercury. This would tend to reduce the persulphate to lphate. Mercury cannot be rubbed up with protosulphate, es not oxidise the surface, so the mercury is not "killed," llects in a globule. The mere fact of the mercury mixing that the sulphate is bad.

Mercury.

st the effect of impurities, some amalgam containing silver, , and zinc was taken. Sodium amalgam was added, and ole shaken up with salts of lead, iron, antimony, platinum, . The amalgam was then shaken up well with persalts ury. The mecuries to be tested were put in little crucibles lution of mercurous nitrate. After a few minutes they all

Temperature Coefficients.

The temperature coefficient of several cells was taken with some care. Three cells were tested first. They were put in a bath at about 30deg. C., the temperature being taken at each reading, and the water slightly stirred.

1,682	0·000312	and	0·000340
1,684	0·000861	,,	0·000840
1,683	0·000297	,,	0·000308

The reason for the discrepancy between the first and second reading of each cell is clear; the cell was colder than the water at first, then, as the cell warmed and the water cooled, the cell was left a little hotter than the water in which the thermometer was placed. Some days later the following readings were taken. In this case I kept the temperatures nearly constant by adding hot water.

1,680	0·000287	1,685	0·000492
1,682	0·000421	1,688	0·00085
1,683	0·000324	1,689	0·00042
1,684	0·000756		

Of these cells, 1,680, 1,683, 1,689, had dilute solutions, made up of equal weights of water and $ZnSO_4 \cdot 7H_2O$. 1,680 and 1,683 differed only in the mercury paste; 1,683 gave different coefficients on the two days. The variations in the other cells may be easily explained. If a cell with the zinc at the top has its solution saturated at, say, 15deg. C., and is then heated, the solution round the zinc is no longer saturated. The temperature coefficient of the cell depends on its past history in fact, and is lower in spring than in autumn. An H cell, or a tube cell, with crystals of zinc sulphate in contact with the zinc always has its solution saturated at both plates. 1,682 is an ordinary cell, but the zinc is at the top, hence its low temperature coefficient when heated. If left at 30deg. C. for a few weeks and then cooled, no doubt its temperature coefficient would rise to 0·0008 or 80. 1,684 is an H cell with crystals in both legs 1,685 is an electrolysis cell, with zinc at top. 1,688 is a tube cell, with crystals in both tubes, hence its high coefficient. It is thus clear that the temperature coefficient of a cell may vary from day to day according to its treatment, and may, perhaps, vary 100 per cent. between winter and summer. Even a variation between ·0008 and ·0006 means an error that may in extreme cases amount to something like a half per cent.—that is, it may be outside the limits I have here taken as worth considering. My water bath differed some two or three degrees from one evening to another, and, no doubt, varied more during the day and night. A new cell would thus be saturated at, say, 20deg., while the standard was saturated at, say, 15deg. If the coefficient of one was 0·0008, and of the other 0·0004, the error might easily be 0·0012 due to that alone. To avoid this difficulty the solution must be kept saturated by using the H or tube cell. Some authorities push the zinc into the paste. This may give the same result, but the zinc then amalgamates too much. Sometimes it has beads of mercury hanging to it, and if these are the only surfaces exposed the E.M.F. may be too low. Over-amalgamation also often detaches the zinc by weakening the solder. Moreover, the formation of so much zinc sulphate may use up all the water, thus rendering the cell dry, or producing a less hydrated salt.

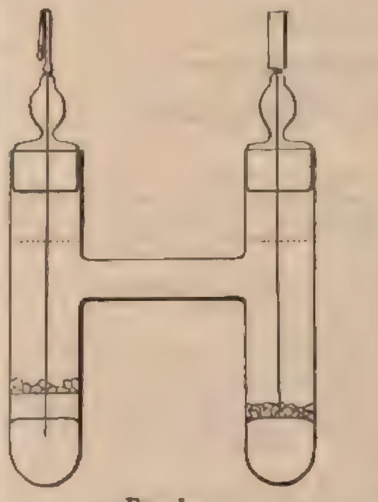

Fig. 1.

Fig. 2.

It would seem better to use a weaker solution. Prof. Carhart and others have proposed saturating at 0deg. C. It seems much simpler to use a standard solution of sulphate made by weighing. There is no particular advantage in saturating at 0deg. C. Weak solution cells have the very great advantage of low internal resistance. No doubt, crystals of zinc sulphate also lessen the available surfaces of the metal and lessen the current that can be taken without polarisation. The construction of the H cell is shown in Fig. 1. One leg contains amalgam with crystals on it, and the other paste. Platinum wires are sealed through glass stoppers, and end in little bracelet snaps. The stoppers are smeared with vaseline to prevent creeping. Fig. 2

is a tube cell. A test tube with a foot has a cork with two holes in it. Through one of them the tube with internal wire is led to the bottom. The mercury and paste are poured in through a funnel. The zinc tube is then pushed through the larger hole in the cork: it contains the amalgam, and has three holes in the side. It is strong to resist fracture. Solution is poured in gently above the level of the first hole. Rangoon oil is poured in over the level of the second hole. The third lets the air out. The zinc connection is then put in, with its cork fitting the smaller tube. If the solution is saturated, the inner tube must be long, so that the zinc surface is on a level with the crystals on the paste. If a dilute solution is used, the inner tube is shorter. This form of cell is convenient for immersing in a bath, and the zinc tubes can be taken out and changed, or tried in other cells.

Prof. Carhart mentions the effect of pressure on Daniell cells. I tried exhausting a Clark cell a third of an atmosphere, and raising its pressure, but though that must have affected the tendency of the liquid to evaporate, it made no perceptible difference in the reading.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts for last week amounted to £4,186.

City and South London Railway.—The receipts for the week ending 22nd inst. were £728, against £653 for the week ending 15th inst.

Electric Installation Company.—Letters of allotment in the Electric Installation and Maintenance Company, Limited, for the supply of electricity to the Crystal Palace, Sydenham, and district, have been posted.

The London Platino-Brazilian Telegraph Company announce that the half-yearly coupon on the 6 per cent. debentures, due on September 1st, will be paid by Messrs. Glyn, Mills, and Co., Lombard-street, E.C.

Western and Brazilian Telegraph Company.—The receipts for the week ending August 21, after deducting 17 per cent. of the gross receipts payable to the London-Platino Brazilian Telegraph Company, were £2,812.

New Company.—The Electric Welding Company, Limited, has been brought out at last. The capital has been put at £460,000 in 25,000 ordinary £10 shares and 1,000 founders' shares of £10. One-third of the ordinary shares are taken by the vendors, and the remainder are offered to the public that is, the vendors are to have £83,330 worth of shares. The Board is made up of the following names: Sir George Barclay Bruce, past president of the Institution of Civil Engineers; E. Ashmead-Bartlett, Esq., M.P., 6, Grosvenor-street, London, W.; Captain A. H. Chapman, J.P., Messrs. Clarke, Chapman, and Co., Victoria Works, Gateshead-on-Tyne; Wm. F. Gooch, Esq., J.P., managing director of the Vulcan Iron Works Company, Limited; Joseph Kincaid, Esq., M.I.C.E., director of the York Engineering Company, Limited. The consulting engineer is Sir Frederick Bramwell, Bart., F.R.S., past president of the Institution of Civil Engineers, 5, Great George-street, Westminster. The prospectus states that "This Company has been formed to acquire the British patents in respect of Prof. Elihu Thomson's inventions for the electric welding and working of metals." One of the welding machines can be seen at work at the Company's depot, Fanshawe-street, Hoxton.

PROVISIONAL PATENTS, 1891.

AUGUST 17.

13865. **Improvements in apparatus for giving notice, by means of electricity, of the heating of bearings.** Edmund Edwards, 35, Southampton-buildings, London. (Anton Backhaus, Germany.)

12880. **Aero dynamic motive power apparatus.** Joseph Desmaroux, 53, Chancery-lane, London.

AUGUST 18.

13917. **Improvements in telegraphing.** Daniel H. Smith, 141, Bath-street, Glasgow. (Complete specification.)

13926. **Improvements in electric locomotives and in electric conductors for use therewith.** Llewelyn Birchall Atkinson, Claude William Atkinson, and Frederick Hurd, 1, Queen Victoria-street, London.

13927. **A unison apparatus for printing telegraphs.** Henry Van Hoevenbergh, 1, Queen Victoria-street, London.

13936. **Improvements in and relating to electric motors, chiefly designed for use in connection with ventilating fans.** Charles Jacob Kintner, 45, Southampton-buildings, London. (Complete specification.)

13942. **Improvements in or connected with apparatus for completing and interrupting electric circuits.** Thomas Parker, John Harold Woodward, and Edmund Scott Gustave Rees, 47, Lincoln's-inn-fields, London.

AUGUST 19.

13961. **Appliances for an electrical parcel exchange system.** Alfred Rosling Bennett, 22, St. Albans-road, Harlesden, London.

14023. **Improvements in electrometers.** Carl Raab, T chambers, London.

14040. **Improvements in electric lighting and exting apparatus for gas-burners.** Henry Harris L Southampton-buildings, London. (Axel Orling, Sw

14042. **Improvements in electric lampholders.** Oscar Cooper, 54, Fleet-street, London.

AUGUST 20.

14063. **Improvements in telephonic transmitters.** Al Marr, 70, Market street, Manchester.

14067. **Improvements in moulds and machinery for the facture of glass switch-slabs for electrical and purposes.** Dan Rylands and Benjamin Stoner, S House, Stairfoot, near Barnsley.

14084. **Improvements in electrically actuated time-c apparatus** Joseph Appleton and William Thomas 77, Chancery-lane, London.

14089. **Improvements in electrical measuring app** Anthony Reckenzaun, 11, Furnival-street, London.

14096. **Combination electric lock** James Graham Th 23, Southampton-buildings, London.

14097. **Improvements in telephone transmitters, methods adopted for the transmission of ar speech, musical, and other sound-waves.** Luzerne Todd and John Todd, 13, King-street, C London.

14134. **Improvements in thermo-dynamic machines, apparatus and appliances connected therewith.** Henry Watkinson, 15, St. James's-row, Sheffield.

14150. **Improvements in electric fire detectors or** Harwood Morgan, 55, Chancery-lane, London. Dion, France.)

14171. **An improvement in car conductors from over electric cars** George Sylvester Grimstone, 28, ampton-buildings, London.

AUGUST 22.

14217. **A new or improved printing telegraphic ap** Sacco Gospare and Luigi Giacomini, 54, Cast London.

14234. **Improvements in and relating to electric ra** Michaelangelo Cattori, 45, Southampton-buildings, (Complete specification.)

14236. **An improved method of arranging apparat generating and distributing electricity by alt currents.** Henry Robert Low and George Edward Pritchett, 41, Beaconsfield-road, Twickenham.

SPECIFICATIONS PUBLISHED.

1882.

4303. **Electrical storage batteries.** Frankland. (Second 6d.

1888.

NOTES.

Russian Exhibition.—An international exhibition is announced, under the auspices of the Russian Government, at Odessa in 1894.

Lignite.—The use of lignite as a substitute for coal, from which great things were expected in Italy, has proved not to have the value claimed.

Melun.—Negotiations are in progress between the Municipality of Melun, France, and the local company for lighting the public lamps by electricity.

People's Palace.—It has been decided to light up the People's Palace at Whitechapel with electric light. Messrs. Slingo and Brooker are to superintend the installation.

Dissolution of Partnership.—We see it announced that Messrs. Johnson, Matthey, and Co., Hatton garden, the well-known assayists and metallurgical chemists, have dissolved partnership.

Change of Offices.—The Brush Company are, we understand, removing their central offices from Belvedere-road to their premises opposite the Mansion House Station, in Queen Victoria-street.

Carbon Works.—As will be seen from our advertisement columns, Messrs. Wheatley Kirk and Co. have for disposal a small compact works, with engine, presses, grinding plant, and furnaces for manufacture of carbon, with stock of material, as a going concern.

Guernsey Electric Railway.—As the Channel Islands are outside the provisions of the Board of Trade, the supervision of the erection of the line is being carried out by the Special States Committee, who have appointed Mr. Bernard Drake as their electrical adviser.

Testing Cell.—The Mining and General Electric Lamp Company are now making a very small lithanode cell, suitable for testing purposes. The total weight is 2½oz., including terminals and electrolyte. Its capacity when discharged at the rate of ·1 ampere is one ampere-hour.

Helmholtz Medal. — In commemoration of Prof. Helmholtz's seventieth birthday a medal like that of Copley is hereafter to be struck by the Berlin Academy. It will bear the portrait of the *savant*, and is to be given every two or three years as a reward of merit to an eminent German man of science.

Sunderland.—An application was made by Mr. R. J. Charlton to the Sunderland Town Council for permission to lay a pipe across the street, underneath the carriageway, for the purpose of conveying an electric wire from Mr. Thornton's Theatre Royal to Mr. Laing's bar. The matter was referred to the Electric Lighting Committe.

Electric Dinner Effects.—At the dinner given during the recent visit of the French Navy to Portsmouth, some striking effects were obtained at the dinner table in the Jan Van Beers' style, by lighting up the table (which was of glass) underneath, so as to glow in the "red, white, and blue" of the familiar tricolour. The idea was duly applauded.

Books Received.—"The Electromagnet and Electromagnetic Magnetism," by Silvanus P. Thompson, D.Sc., B.A., F.R.S., published by Messrs. E. and F. N. Spon; also "Electricity in Mining," by the same author and publisher. This latter pamphlet gives the full text of the author's lecture at Cardiff during the recent meeting of the British Association.

Cables to Brazil.—France and Brazil are now in telegraphic communication with each other *viâ* the Antilles. On Wednesday the first official message was transmitted over the cable congratulating President Carnot on the fact. On the same day the first direct cable between the United States and Brazil, stretching from Punta Rassa, Florida, to Para, was opened.

Paris Telephone.—M. Jean P. A. Martin, member of the Association of French Stenographers, writes to the *Times* bearing his testimony to the efficiency of the Paris-London telephone, which he uses every day, but wishing to know why, when telephoning is perfectly distinct between London and Lyons, redtapeism or other cause prevents the use of the line direct to Lyons.

Shoreditch.—On Tuesday the Shoreditch Vestry, Mr. N. Moss, L.C.C., presiding, decided to obtain power to supply electricity within the parish of Shoreditch for public and private purposes; and to memorialise the Board of Trade for a provisional order under the Electric Lighting Acts, 1882 and 1888, to enable the Vestry to supply the parish or any part thereof with electricity.

Salford.—The Salford Borough Council, on Wednesday, adopted a resolution of the General Health Committee accepting the tender of the Manchester Edison-Swan Electric Lighting Company for the electric light installation required at the sanatorium, in accordance with specifications prepared, for the sum of £1,312. Mr. Alderman W. Robinson said that they would save £300 by adopting the system proposed.

Missing Letters.—Our readers will doubtless have noticed in the daily papers this week the statement that a large number of letters have never reached their destination, and that over 2,000 have been just discovered. Among these were some addressed to this office. If any of our correspondents have sent any important communication which has not been attended to they would do well to communicate again.

Waterfalls.—The *Moniteur Industriel* states that an English syndicate is visiting France to investigate the various falls of water with a view to purchase. The price of waterfalls is evidently likely to go up now that light, power, and heat can be so easily manufactured out of their hydraulic power. The French papers remind their readers that a good waterfall has now become to all intents and purposes an "everlasting coalfield."

A Fire Detector.—A neat and simple fire alarm has recently been devised, consisting of a stud placed in a porcelain base and surrounded by, but not touching, a knob of fusible metal of considerable surface projecting into the room. The electric circuit is arranged to energise a relay on the slightest contact of the metal with the stud, and the whole is so cheap that they might be placed in every room of a mill or public building at small cost.

Partnership.—Mr. J. Edward Waller, who has for many years been associated with Mr. Joseph Kincaid as his manager, has entered into partnership with Mr. Edward Manville, consulting electrical engineer. Messrs. Waller and Manville will carry on at 39, Victoria-street, Westminster, S.W., the profession of consulting civil and electrical engineers, a desirable combination in the rapidly-advancing condition of the applications of electricity.

Obituary.—We much regret to have to record the death of one of the members of the Old Students' Association, at the age of 22, Mr. George T. S. Müller, who was well known to most of the members of the above-named association, as he was one of the most regular attendants at

meetings and social events. While bathing at Hampstead on Friday morning, August 28, being suddenly seized with cramp he sank, and was drowned before help could be given.

Magnetic Variation.—The hydrographic department of the Government has given notice of a curious error in one of the Admiralty charts, the correction of which is of importance to mariners navigating Liverpool Bay. It appears that in certain copies of the Admiralty plan, No. 1,951, for Liverpool Bay, it is stated that the magnetic variation taken in 1888 increases 9deg. annually. This should be altered to "Magnetic variation in 1888 decreasing 8deg. annually."

Electric Railways in France.—The General Council has granted the concession for the extension of the electric tramway from Montferrand to Clermont, to Royat, and to the summit of Puy-de-Dôme. This project comprises the adherence system, the gear system, and the cable system. It is expected that within 18 months the formalities and necessary works will have been completed, and that excursionists and visitors will be able to make the ascension of Puy-de-Dôme by railway.

Visit to Frankfort.—It is announced that 20 members of the Electrical Trades Section of the London Chamber of Commerce have arranged to depart for Frankfort on September 6. The president of the Electrotechnical Congress has written to assure them of welcome, and to mention that tickets for the congress will not be sent, but will be given on personal presentation at the office of reception opposite the railway station. Other members not mentioned on the list may also obtain tickets on application.

Shrewsbury.—At the Shrewsbury Town Council last week Mr. S. M. Morris moved that the consent of the Council be granted to the application of the Shropshire Electric Light and Power Company, Limited, to the Board of Trade for a license to erect and maintain electric lines and works, and to supply electricity within the borough of Shrewsbury, subject to power being reserved for the Council to purchase at the end of either seven, fourteen, twenty-one, twenty-eight, or thirty-five years, at a price to be agreed upon by arbitration. This was seconded by Mr. T. M. How, and, after a brief discussion, agreed to.

Gas, Water, and Electric Light Directory.—We are in receipt of the "Gas, Water, and Electric Lighting Companies' Directory for 1891," edited by Charles W. Hastings, and published by Hazell, Watson, and Viney. The work contains an account of every town with gas, water, or electric light, with very full particulars of formation of company, capital, dividends, names of officers, population, and so forth. The work should be extremely valuable as a book of reference to those interested in municipal lighting questions. There is also a useful chapter on the rating of these companies.

Free Telephones.—The Consolidated Telephone Construction and Maintenance Company, Limited, are advertising that they—the sole manufacturers of telephones for all the exchange companies in the United Kingdom since the year 1881, as also sole manufacturers of telephones for use abroad since the same year—can, by an agreement with the National Telephone Company, Limited, of Oxford-court, Cannon-street, London, supply telephones of all kinds under the Crossley, the Gower-Bell, the Hunnings, the Blake, and their kindred patents, for sale outright, free of all royalties and all claims whatsoever.

Substitutes for Platinum.—Another substitute for platinum as regards similarity of coefficient of expansion with that of glass is announced, the discovery of Mr. R. A. Fessenden, of Roseville, Ne[illegible] This consists of an alloy of iron, nickel, cobalt, silicon, and gold or silver. The advantage claimed is for the manufacture of vacuum tubes, but it is very evident that if in the near future incandescent lamps are to be as cheap as lamp glasses, the reduction in the cost of connections in the substitution of some alloy for the expensive platinum, now solely used, would prove a most important element in the case.

Electric Light and Fishing.—A correspondent of *Land and Water* states that fishing all along by Totland Bay, Isle of Wight, was always poor, but that since the setting up of the search-light for the forts it has become worse. He also heard that there used to be a very good place for fish near the lighthouse at St. Catherine's Point, but that the electric light has driven them all away, and that now it is quite useless putting out nets in a spot where a few years since a decent haul was looked on as a certainty. He solicits opinions on this matter from those who are more versed in sea fish and their ways than he is himself.

Lightning at Keighley.—On Friday a heavy thunderstorm broke over the town of Keighley, accompanied by heavy rain, and a cottager and his family had a narrow escape. About half-past four o'clock the man, whose name is Bartle, was awakened by a thunderclap, and found that the bedroom was a mass of flame. His wife and family, who were also asleep upstairs, jumped up in a state of great alarm, but beyond a black eye, received by Bartle himself, and a slight injury to his wife's arm, no personal damage appears to have been sustained. The house windows were for the most part shattered, along with parts of the woodwork.

Electric Fittings.—The influence of the spread of electric lighting is nowhere more forcibly shown than in the way the trade in gas fittings is slowly but gradually dwindling away, leading many hitherto exclusively gas fitting firms to go into electric fitting. Amongst these, Messrs. E. Emanuel and Sons, Limited, of 4, High-street, Marylebone, are turning their attention to electric switches and lamp fittings. We have recently called at their showroom and were shown some handsome switchboards on slate in teak cases, fuses, wall plugs, and other apparatus. They also keep in stock brackets, electroliers, and table lamps in brass and hammered iron.

Galvanic Action in Ice Cream Machines.—A new danger has been discerned due to unsuspected electrical action. Dr. G. S. Hull, it is stated, has recently carried out experiments with ice cream freezers, and he finds that electrolytic action takes place between the freezer and the paddle when the ice cream and fruit salts are introduced, which results in the production of poisonous salts of copper and zinc. This is probably the explanation of the mysterious deaths by poisoning which have resulted from eating ice cream. The remedy is easy: the freezer and mixing paddle should be of the same material. Journals circulating in hot climates would do well to widely circulate the knowledge of this fact.

Canterbury.—At the Canterbury General Purposes Committee it was stated that the town clerk had communicated with the Dover Town Council, who were in the same state as Canterbury, having only heard from the Brush Company. Mr. Wells wanted to know whether there was not a ring of the companies. Mr. Cross said that the Brush Company's offer should be considered, and a definite conclusion come to at once. Alderman Mount said he would put a proposal forward at the next meeting to this effect. He said the company had offered to repay the £200 paid for the provisional order, and to carry out the

work without charging a penny or asking for the public light contract. What the Council could want better than that he did not know. The matter then dropped.

Column Printing Telegraph Machines.—A writ was on Saturday served on the Exchange Telegraph Company by the solicitors to the Column Printing Telegraph Syndicate, Limited, in respect of an alleged infringement of the Column Syndicate's patents, and a notification has been issued to all users of the alleged infringing machine that they are legally liable if they continue to use the instrument. The allegation of the plaintiffs is that they have the only practical column printing telegraph instrument in existence, and that the Exchange Telegraph Company had not been able to make a machine under their own patent to accomplish the same results, or to work satisfactorily, until they had infringed a material part of the instrument belonging to the Column Printing Syndicate.

Electric Tanning Patents.—An interesting point to patentees and commercial men in general has arisen with regard to the patents of the British Tanning Company. The patents for a process of electric tanning granted in Paris to Messrs. Worms and Balé were also taken out in America and in Great Britain and Ireland. By some error the United States patents were published prior to the British patents, and these became invalidated, and were the subject of an adverse decision in the Chancery Courts last January. The company might have availed themselves of the Act of Convention, by which the date of the American patent could have been put back to that of the French patent. But they have adopted the other course open to them, and a special Act of Parliament has been passed, which received Royal assent on July 28th, the effect of which is to restore the patent rights.

Telephones and Coast Guard Telegraphs.—At the meeting of the Associated Chamber of Commerce in Dublin, on Wednesday, a resolution was proposed by Mr. Plummer, of the Newcastle and Gateshead Chamber, to the effect that as the telephone patents are expiring, the Post Office should be communicated with, to place the telephonic system of the country under such regulations as would give the public the greatest facilities. An amendment by Mr. Massey, of Hull, suggesting that the matter was one for local enterprise, was, after a good deal of discussion, unanimously adopted. On the motion of Captain Bailey, of Plymouth, seconded by Mr. Hunter, and supported by Sir Henry Waring, the association expressed its conviction that the coast guard stations, the shore and rock lighthouses, and the lightships of the United Kingdom, should be placed in telegraphic or telephonic communication with the general telegraph system of the country.

Accident to Train-Lighting Dynamo.—A singular accident occurred on Thursday last week to the 9.17 Great Northern train from Barnet to Moorgate-street. The carriages are lighted by electricity, the current being supplied by a dynamo placed in a special compartment attached to the rear guard's van. Soon after the train left the Finchley Station, the rear guard discovered that flames were issuing from the electrical chamber, and that fire had taken considerable hold of the woodwork. By opening the air-valve, he released the vacuum brake, and brought the train to a standstill. A gang of porters were quickly on the spot; and by the plentiful use of water, they subdued the fire. A telegram was despatched to Finsbury Park, where an electrician met the train. It was then found that the dynamo was intact, and the light was available for the remainder of the journey. It is conjectured that undue friction in connection with the dynamo had set light to the woodwork of the chamber.

Odessa.—Her Majesty's Consul-General at Odessa (Mr. T. B. Sandwith), writing to the Foreign Office, mentions that the port of Odessa (in contradistinction to the town of that name), having for many years remained unlit even by oil lamps, and within two years only being lit by gas, has at length been illuminated by electricity. An installation has been completed at a cost of 80,000 roubles (£8,400). This consists of 64 arc lamps of 2,000 c.p. each, and of two lanterns, one at each end of the breakwater which runs the whole length of the port. The illuminating power is generated by two of Willans's vertical engines of 67 h.p. each. The Odessa Town Council has assigned a sum of 20,000 roubles (£2,100) annually for the working expenses. The new installation is regarded as a great boon by the shipping interest, the whole port being brilliantly lighted, so as to admit of the loading and discharging of steamers by night as well as by day.

Electrolytic Separation of Zinc.—The process introduced by M. Nhansen may be applied to the electrolytic separation of zinc by employing a bath, the temperature of which can be lowered according to the density of current employed. The inventor notices that the temperature must be lowered as the density of current is reduced. The mean of 120 observations is shown in the following table:

Density in amperes	State of metal obtained. 10deg.	20deg.	30deg.	40deg. Cent.
10	compact	spongy	spongy	spongy
50	—	semi-comp	—	—
100	—	compact	semi-comp	—
150	—	—	compact	semi-comp.
200	—	—	—	compact

If it is desired to work with a density of "100 per square metre," the bath, to obtain compact metal, must be kept about 20deg. C. In commercial practice it is always preferable to use currents of less than 50 amperes density, and to maintain the temperature below 10deg. C. by means of ice or refrigerating apparatus.

Electric Melting and Welding.—A new claimant for honours in electrical welding or forging is receiving attention in Boston, according to the New York *Electrical Review*. An exhibition was recently given by Mr. George D. Burton. The Press accounts state that one experiment was the melting into liquid form of a bar of steel an inch in diameter and 12in. long in 45 seconds, without the temperature of the room being raised a single degree from its normal condition. Another thing shown was the making of a steel railroad spike. The bar was cut into the required length, the pieces passed through the electrical machine, where one end was heated, and then to a die, which shapes the head on to the heated end, the point being compressed into the shape without heating. Another exhibit was the forming of an auger screw, the flat bar of iron being fastened in the machine at the two ends and heated almost instantly, and then twisted into the required spiral by the automatic turn of the machine. These experiments were witnessed by Dr. W. H. Wahl, Prof. Van der Weyde, and others.

Crystal Palace Exhibition.—The Crystal Palace Electrical Exhibition, to be opened on the 1st January next, has now received the sanction of the Board of Trade, and is duly certified as an international exhibition, under the provisions of the Patents, Designs, and Trade Marks Act, 1883. This Act provides for the publication of any description of the invention during the period of the exhibition, or the use of the invention for the purposes of the exhibition, or its use by any person elsewhere without the privity or consent of the inventor, without prejudicing the right of the inventor to apply for and obtain provisional protection, and a patent within six months of the opening of the exhibition. The

right of application for registration of designs is also protected by this Act for a period of six months from the opening of the exhibition. The exhibits of her Majesty's Government will include historical telegraphic and electrical apparatus, instruments, and appliances, as well as the modern apparatus and instruments now in use in the Postal Telegraph Department. This exhibit will be arranged under the direction of Mr. W. H. Preece, F.R.S.

Lightning Conductors.—It may be remembered that in the spring of 1888 Prof. Oliver Lodge, F.R.S., gave two lectures on "Lightning Conductors" to the Society of Arts, in which he promulgated several revolutionary views on the subject, and supported them by a series of direct experiments with Leyden jars. The experiments also branched off into a study of electric waves, a subject which was being simultaneously worked at in Germany by Hertz. At the British Association meeting in Bath that same year, Prof. Lodge's views were goodnaturedly controverted by Mr. W. H. Preece, partly for the purpose of raising a discussion and partly because some of them were rather startling. Since then a more complete communication from Prof. Lodge to the Institution of Electrical Engineers and to many scientific periodicals, as well as a recent paper read before the Royal Society, are generally held to have fairly substantiated the new views, and we understand that during the present year Prof. Lodge has been engaged in welding together the principal portions of all this literature, with sundry additions, and that Messrs. Whittaker and Co. propose to issue it as a large volume of the Specialists' series in the course of the autumn.

Bolton Technical School.—The careful consideration of the Bolton Technical School Committee has been given to the question of engines, and they have decided to put down the Griffin double-acting gas engine of Messrs. Dick, Kerr, and Co., Kilmarnock and London. In this engine there is an explosion every revolution, first on one side of the piston head and then the other, which ensures great regularity in running. The consumption of gas in these engines is stated to be as small as in best single-acting engines. Two engines are required, each to indicate 35 h.p. One will be used to work the machinery and the other the electric lighting, but they will be so arranged as to be worked separately for either purpose, so that any accident to either engine would not completely stop any part of the work of the school. In addition to the large engines, a 3-h.p. engine will be provided, and serve as a starting engine for the large ones, and also will be available for use when it is required to run only a small portion of the machinery. This will enable students to use some of the machinery for special purposes without the necessity of running the large engines, and will be a great convenience in the effective working of the school.

Manchester.—At a meeting of the Manchester City Council on Wednesday, Mr. Brooks moved the approval of the proceedings of the Gas Committee, together with a resolution to apply to the Local Government Board to sanction the borrowing of £150,000 for the purpose of carrying out the electric lighting scheme of the Corporation. Sir John Harwood, in seconding the resolution, said that for some time the committee had been taking the opinion of the best men in the country as to the best mode of putting down an installation of electricity. They consulted a considerable number of the best-known electrical engineers, and that morning he had a final conference with Dr. Hopkinson, who, he believed, was one of the best authorities in this country. The whole of the arrangements had been placed in his hands. The scheme would involve o[illegible] for 12 months after it was finished. The c[illegible] the hydraulic power and electricity schemes would work in harmony, and they expected that under the same rule, and very largely under the same administration, they should be able to have the same motive power, so far as steam was concerned, driving those two forces, and producing for Manchester the very best modern approved form of both hydraulic power and electricity. The resolution was adopted.

Artificial Production of Rain.—Within the last three weeks, according to the New York correspondent of the *Standard*, nine showers of rain, of which one was considerable, have been artificially produced in a region almost rainless normally. The district selected for experiment by the United States Agricultural Department is near the midland staked plains of Texas, a grazing country, where agriculture is impossible because of the aridity of the climate. For more than three years no rain has fallen there, except in very occasional small showers. On Wednesday the vegetation was parched, the sky unclouded, the barometer at 30·5, the hygrometer between dry and very dry. The cowboys, who are shrewd judges of the weather, declared that rain was impossible. With this condition of the atmosphere the following experiment was tried: Five balloons, each 12ft. in diameter, and charged with one-third oxygen and two-thirds hydrogen, were exploded by electricity on time fuses, at heights ranging from 1,000ft. to five miles. Three hundred and fifty pounds of Rackarock dynamite was also exploded in scattered packages of from 10lb. to 20lb., at intervals of one minute, ending at 10 p.m. At three o'clock the next morning a sharp clap of thunder was followed by heavy rain. At sunrise a beautiful rainbow was seen. The rain stopped at eight o'clock, but began again to fall after more explosives had been used.

Cause of Heat in Electric Welding.—According to Prof. Elihu Thomson, says an exchange, it is not the extra resistance at the break that gives rise to the heating in electric welding. The imperfect contact there no doubt hastens the heating of the joint, but a solid bar placed between the clamps of an electric welding machine can also be raised to the welding temperature. The real cause of the concentration of the heating between the clamps is the relatively greater conductivity of other portions of the welding circuit, which is usually composed of massive copper conductors, kept cool in the case of large work by the circulation of water. By keeping the conductors cool in this way their resistance is maintained constant, and an accentuation of heating effect follows at the joint where the rise in temperature increases the resistance. In large works it has been found that hydraulic power can be advantageously employed both for clamping and making contact with the pieces to be welded or worked. In dealing with metals such as lead, tin, zinc, the temperature required for welding is so low that the metal never glows, and the progress of the breaking cannot be watched with the eye. By properly shaping their ends, leaden water-pipes can easily be welded together end to end. The meeting edges should be thinned so as to reduce the surface of contact below the area of the pipe wall. Joints thus made are very good and sound. Most metals can be welded without the use of a flux, but for good work a flux is often desirable.

The Marvin Electric Drill.—The Marvin electric percussion drill, a recent American invention, consists of an iron bar, to which a drill is connected, reciprocating axially between two solenoids intermittently energised by pulsations of current delivered to the two coils in alternation over separate circuits from a special dynamo. The two solenoids are mounted in a boiler tube casing, and the whole apparatus is mounted upon an adjustable support. As the coils are alternately supplied with pulsations of current over

separate circuits from a special dynamo, no commutating devices or sliding contacts are required either upon the drill or in its vicinity. The moving parts are simply an iron rod travelling axially, and a ratchet arrangement that serves to turn the drill slightly at each stroke. The whole machine is designed to endure the roughest kind of abuse in mines and quarries. The machines now ready are capable of drilling holes from 1ft. to 8ft. deep, and from 1in. to 2in. in diameter. They will cut about 8ft. per hour in granite, and require about 5 h.p. The drill travels in synchronism with the dynamo, and by feeding the machine up to the rock the stroke may be made as short as is desired for starting a hole, while the number of strokes per minute remains the same. A peculiar property of the machine is that when the machine is withdrawn out of striking range of the rock the plunger immediately loses its stroke. It takes up a position about midway between the coils, and its motion becomes a mere quivering. There is no pounding against buffers, as the rod is perfectly cushioned by the magnetic action of the coils. At full stroke the drill has an excursion of about 4in., and strikes 650 blows per minute. It is of about the same weight and bulk as an air drill of the same capacity.

Arbroath.—The electric light has just been introduced in a practical form into Arbroath by Mr. Andrew Lowson, flaxspinner and manufacturer. The installation has been carried out by Messrs. Lowdon Bros., Tay-street, Dundee, and the work having now been completed the light was last week submitted to a final test. The installation is similar in most respects to numerous others fitted up in the district by the Messrs. Lowdon. The total number of lamps is about 300, these being distributed over the factory, the preparing, spinning, and winding departments, the mechanics' shop, and offices. The dynamo, placed in the engine-room, is a compound-wound "Manchester," capable of developing a current of 180 amperes at 105 volts, and also of supplying 300 incandescent lamps of 16 c.p. each. The dynamo is driven by the main factory engine, power being transmitted from the main shafting to a pulley in the engine-room. A switchboard is fitted up in the engine-room. In the factory about 160 lamps are fitted up, one light being provided for each loom. The lamps are suspended by flexible wire ropes from the wooden casings, and are hung about 2½ft. above the centre of the looms. Each lamp is provided with a reflector, the whole of the illuminating power being thus concentrated on the loom. Judging from the results of the test a single lamp appeared to give sufficient light for each loom, and the shadows were considerably less than gas light. Two lamps are sufficient for the effective lighting of each pass in the spinning department. In the mechanics' shop ingeniously contrived hand-lamps are provided for the use of the workmen. Wall sockets are fixed at intervals along the benches, so that the workmen can have lamps which can be either hung up, or placed upon the bench at the spot most convenient for him. The trial was witnessed by a number of leading manufacturers and gentlemen belonging to Arbroath.

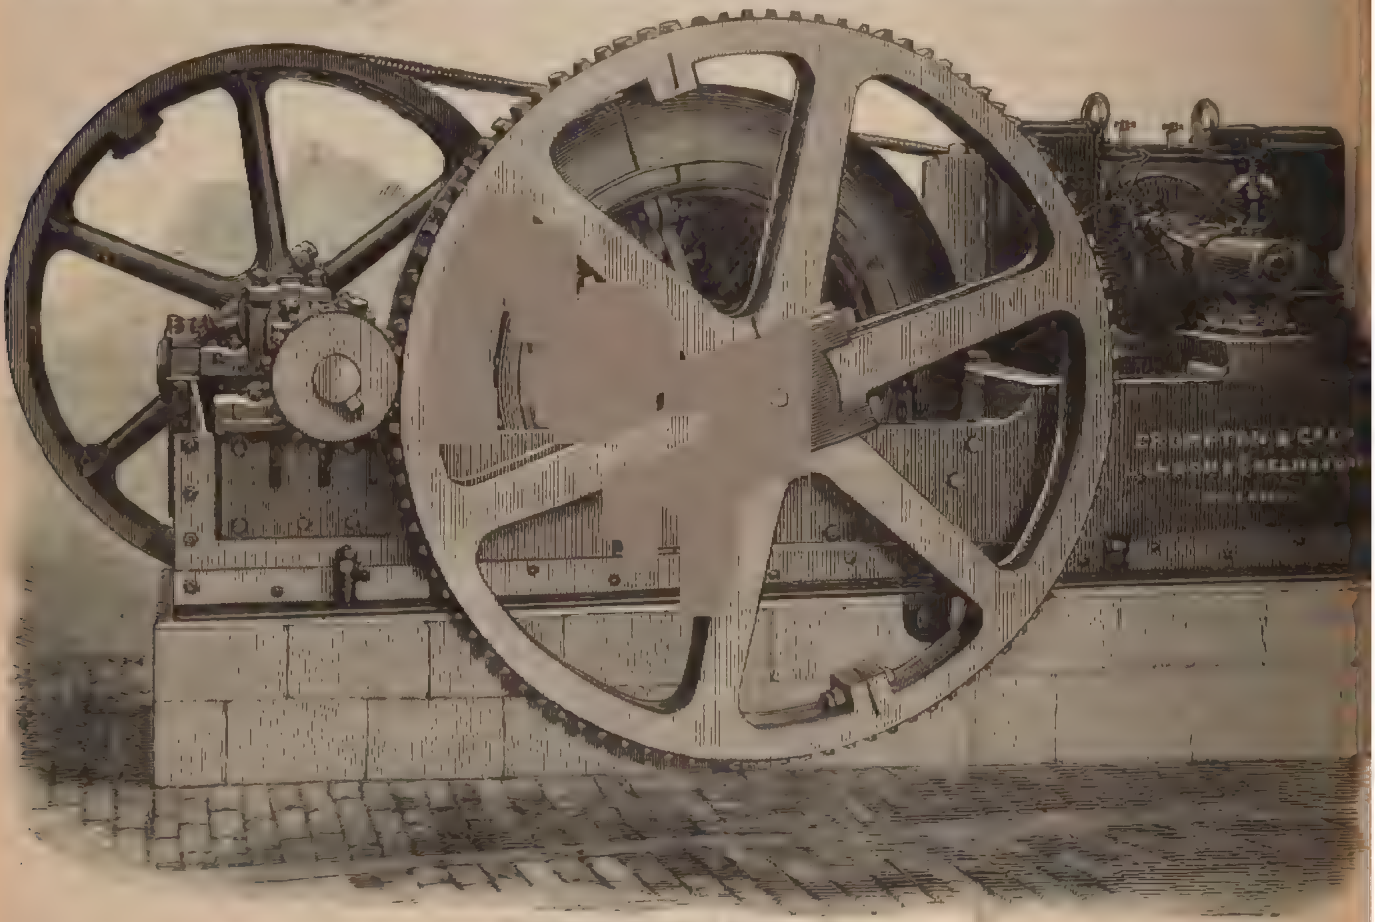
Lithanode.—The use of the lithanode cells invented by Mr. Desmond FitzGerald is, we are glad to be able to record, coming into practical usefulness. Lithanode is not "compressed peroxide of lead," as is sometimes supposed; for, however strongly this material may be compressed, the resulting plate will disintegrate when immersed in water. It is produced from protoxide of lead, or litharge made into a pasty mass with a solution which causes the material to set so that it will no longer fall to pieces in a fluid; the moulded mass is then converted into peroxide of lead in an electrolytic bath. By the use of lithanode, a peroxide plate which is not subject to local action may be constructed; an inoxidisable metal, such as platinum or gold, being in this case used for establishing contact with the plate. A great advantage is thus secured in the construction of an element which will retain its charge for any length of time, even when partly discharged and left immersed in dilute sulphuric acid. In discharging a battery containing lithanode elements it is not advisable to allow these elements to run down beyond the point at which the potential difference between them and a spongy lead element is 1·8 volt—*i.e.*, beyond the point at which the normal E.M.F. of an ordinary lead accumulator has fallen 10 per cent. The electrical capacity of lithanode, when used with the precautions indicated, is almost exactly one ampere-hour per ounce avoirdupois, so that with an element weighing 1lb. 16 ampere-hours may be obtained. It is interesting to note, however, that when the rate of discharge is very high the apparent capacity of the lithanode becomes diminished, the current ultimately falls by reason of polarisations, and the elements require rest before the discharge can be completed to the extent of the full capacity of the lithanode. The rate of discharge obtainable with lithanode batteries varies within wide limits, according to the character of the lithanode, whether dense or porous, the perfection of the contact, the strength of the acid electrolyte, etc. An ordinary rate of discharge, it is stated by the makers, per square inch of lithanode plate ⅛in. thick, is $\frac{1}{14}$ of an ampere, but in some cases the rate exceeds $\frac{1}{6}$ of an ampere.

Bradford Electric Tramways.—With the view of obtaining a good basis of calculation as to the advisability of the adoption of the overhead electrical system for the Wakefield-road tramway, the Tramways and Baths Committee of the Bradford Corporation have been making arrangements for an experiment with overhead conductors. The arrangements, according to the Bradford paper, for this test are now completed, and will be submitted to the Town Council in the minutes of the committee at the next Council meeting. Mr. Holroyd Smith, the well-known electrical tramway engineer, has undertaken to run an electric car on the tram lines from the Midland Station to the Bradford Grammar School, starting from each end every quarter of an hour, for several weeks, for the purpose of proving the reliability of the system; and he hopes also to prove that the adoption of the system for Wakefield-road would not be too expensive a matter. Mr. Smith will provide the car and execute all the necessary works. The Corporation will supply the electric power, and, by the proposed agreement, if the experiment is not a success, they will not be put to any expense beyond the cost of the supply of the electricity. If it be successful the Corporation will contribute £500 towards the cost of the experiment, and if they proceed to utilise the electrical system for the Wakefield-road tramway, they will appoint Mr. Holroyd Smith as the electrical engineer, giving him a commission of 4 per cent. on the cost of the work falling in his department. The Bradford Tramways and Omnibus Company have granted the use of their lines for the purpose on the condition that they shall provide a conductor for the car and collect and retain the penny which it is proposed to charge each traveller. The car will carry 36 passengers, half of them inside and half outside. Further information as to the working of tramcars by this system is to be obtained by the chairman of the committee and the borough surveyor, who will shortly go to Frankfort, a town in which the conditions as to levels are pretty similar to those in Bradford, to investigate the results of the working of electric tramways there.

CROMPTON'S ELECTRICAL HAULAGE PLANT.

Mining engineers are beginning to appreciate the immense advantages offered by electrical transmission. For some time past experiments on a small scale have been carried out in different mines, and sufficient information has been obtained to warrant the introduction of a much larger plant, and the haulage machinery recently installed at Abercanaid Colliery for the Hill's Plymouth Company in South Wales is the latest development. Mr. J. C. Howell, of Llanelly, Messrs. Crompton's South Wales agent, undertook to supply the owners with haulage machinery which would replace 27 horses, many hauliers, and a number of door-boys, and enable the output to be increased by 100 tons per day.

After careful consideration it was decided to accept the offer, and Messrs. Crompton and Co. at Chelmsford set to work to design the most efficient plant for the purpose named. Many points had to be most carefully considered, and besides the necessity of making the plant very compact, the haulage machine was required to be most easily controlled. The winding gear was the usual form employed in the main and tail-rope system, and this was found to work exceedingly well. The motor is a Crompton patent series-wound machine, built to run at 600 revolutions per minute, and take 80 amperes at 450 volts. At starting, when a heavier current is required, it will take 160 amperes without harm. The motor is placed horizontally at one end of a wrought-iron frame, which forms the bed for the drum and spur-wheel. The drum shaft, which is of steel, is driven from a countershaft by means of spur gearing, and the motor drives the countershaft by means of six 1in. ropes. The haulage engine is fitted with two drums 3ft. 6in. diameter and 1ft. wide, which are controlled, as above stated, by clutch and foot brake. This plant will haul coal from three different parts of the pit, and although these are not far from the motor at the present time, it is expected that coal will have to be dealt [illegible] nearly a mile distant. The generating plant comprises [illegible]on dynamo, horizontal pattern, [illegible] a w[illegible]-plate. It is compound wou[illegible] give [illegible]es at 500



Crompton's Electrical Haulage Plant.

volts, running at 550 revolutions. The cable connecting the dynamo with the haulage plant is 3,200 yards long and composed of 37 strand No. 14 high conductivity copper wire, highly insulated with vulcanised bitumen, double taped and served with two layers of jute yarn compounded between each. It is protected by a double sheath of No. 8 steel wire, the first stranding being of 30 wires, and the second 36 wires, laid in reverse directions. The current density is 870 amperes per square inch, and resistance of cable ·3192 ohm, allowing a loss of potential of 51 volts, or 10 per cent.

From the generating plant the cable is carried down the level by the side of the shaft, and between the hauling engines it is fixed on each side of the roadway. In case of "falls" the cable has been constructed so that it can stand a shearing strain of 10 tons per square inch.

A number of visitors were invited by the Hill's Plymouth Company to see the opening ceremony, amongst whom were many connected with collieries in different parts of the country, and many well-known mining engineers. The engineer to the company, Mr. Bailey, stated that his father had put down the first system of rope haulage for mines 30 years ago, and the electric system of haulage now inaugurated would enable the company to increase its output very considerably. The great difficulty in colliery enterprises was the labour cost, and the coal could not be got to the surface unless they had mechanical means of bringing it up long distances. The system of rope haulage by compressed air was very costly, and they were thrown on their beam ends, as it were, when Mr. Howell, of Llanelly, offered to supply this electrical plant. They found that the capital required was only half that of compressed air; while the latter only gave 30 per cent. efficiency, electricity gave 65 per cent., which was a most important improvement. He added that he placed perfect reliance on Mr. Howell's estimates and working, the more especially as since Mr. Howell had erected their electric lighting arrangements at Abercanaid they had never had one hour's stoppage, which spoke well for the machinery and for Messrs. Crompton's work. The machinery must be well made and put up well to act in this manner. He hoped and believed that the electric haulage machinery started that day would prove

most economising machinery ever brought into South les. They found it impossible to go on with horses, and e glad that they had put down an electric haulage nt, and would have great pleasure in showing and laining it to any others interested in such matters.

Ir. Howell stated that this was the first experiment on large a scale underground, and although they had no ortunity of making a trial before that day, he found machinery was in perfect order and answered every ectation. The most important point for colliery owners consider was the fact that the electric haulage plant only one-half that of compressed air machinery. Coal ers had to apply powers at great distances from the rce of energy, and for that purpose he looked upon electrical machinery which had just been erected as a mencement of what would become general in the liery work of South Wales. They could deliver at the end 60 or 65 per cent. of the power generated, which what no other power known could do.

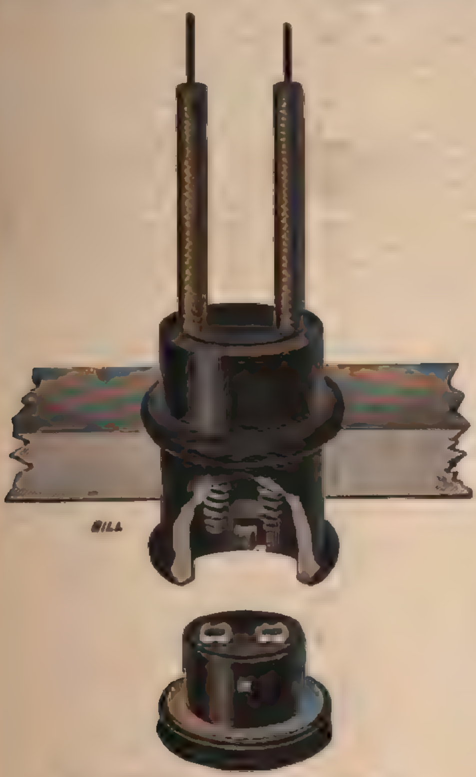
The ceremony was made very interesting by the fact t Mrs. Hankey, the wife of Mr. F. A. Hankey, M.P., naging director of Hill's Plymouth Company, started the am engine, which put the whole plant in motion. er it had been started, a number of engineers and others rested went down the pit and saw the work done by haulage engines, of which they spoke in the highest ns.

"Thus started," says the *Merthyr Express*, "the first trical haulage apparatus in South Wales, the success of ch beyond all doubt will lead to its adoption in every ortant colliery throughout the two countries."

This power installation was referred to by Prof. Silvanus Thompson in his lecture on the Use of Electricity for ing Purposes, delivered at Cardiff on the 26th ult., was also visited by several members of the British ociation, to whom the details of the plant were ex- ned by Mr. Howell.

NEW VITRITE CHEMICAL LAMPHOLDER.

We illustrate herewith a new lampholder, which has n specially designed for use in chemical works, starch



New Vitrite Chemical Lampholder.

tories, underground tunnels, and all places where phurous and other fumes are present. These fumes, it well known, rapidly destroy metal fittings, and engineers who have had much experience with electric light installations in these impure atmospheres have not found reason to be perfectly satisfied with any of the numerous types of holders which have hitherto been introduced for use under these conditions.

The Vitrite Chemical Holder, as the new holder is termed, entirely protects the metal lamp connections from any contact with the outer atmosphere. A special form of "Vitrite" cap is supplied with the holder, which is sent to the lamp manufacturer, when ordering, for affixing to the lamp. A small rubber ring is placed on the cap, which then fits tightly into the holder; the rubber washer rendering the joint air-tight. The connection to the spring of the holder is made in the material of the holder itself, and the piece of the insulated wire attached to the holder affords opportunity for making a proper insulated joint with the permanent connections of the installations. The arrangement of the spring in the interior is exactly similar to that in the ordinary form of vitrite holder. A rim is arranged round the top of the holder to allow of it being supported, if desired, by resting in a hole bored in a piece of wood or other fixture. The holders are being introduced by Messrs. Woodhouse and Rawson United, Limited, who have stocked a large quantity of various types for all requirements.

THE WEYMERSCH BATTERY.

There has always been a demand for a good primary battery for lighting a small number of lamps, say, up to 20, and we suppose there always will be this demand, notwithstanding central stations or gas and petroleum engines. No one with central station mains at his door would think of putting in his own gas or oil engine, far less his battery (unless he were an enthusiastic amateur), but many persons residing in country districts, whose mansions are far away from distributing mains, would and do deliberate between engine and battery, and a secret hankering for something less obtrusive in noise and smell than an engine is constantly manifested by owners of country houses. When the houses are large and the lamps numerous, only an ignorant or prejudiced person would hesitate to decide for an engine, which might be arranged at some little distance from the town. But when wants—and incomes—are more moderate, a battery in an outhouse would often be the best solution, if a constant, dependable, and fairly cheap arrangement could be procured.

We have several times during the last year or two described or alluded to the Weymersch primary battery, which is being introduced by the Weymersch Battery Syndicate, of Victoria-masions, Westminster. This battery, which has been favourably reported on by experts, is very conveniently arranged for simple attention. Several improvements in detail have been recently introduced, and during last and this week an exhibition of the battery, in conjunction with a set of accumulators erected exactly as for a moderate house installation, has been on view, and has been examined with great interest by numerous visitors.

The primary battery is used to charge two sets of E.P.S. accumulators, and the current is withdrawn from the accumulators in series for lighting or for driving motors. The primary battery consists of 12 cells, two boxes of six cells each of the Weymersch battery. The carbons, two in each cell, are placed in two porous pots, side by side, in strong depolarising solution, and the zincs, large thin plates, are hung outside in a weak acid solution—half-pint acid to one gallon of water. The solution can be drawn off by taps and syphons for recharging. The battery gives a steady current of 20 amperes at 20 volts for 20 hours, the cost being given by the syndicate as just over a shilling per unit. The battery is arranged to charge two sets of E.P.S. accumulators, 16 in all, which are charged eight at a time at 20 amperes. These can be charged alternately, and discharged when required in series at 30 volts, at 10 or 15 or 20 amperes. The installation is shown lighting a dozen or so 30-volt 8-c.p. incandescent lamps. A large Bernstein lamp of 100 c.p. is also arranged to be switched on to current from the same secondary battery. This interesting

installation is completed by the demonstration of its application to motive power. From the same source is driven a Blackman electric ventilating fan, which, by the way, has an interesting motor in the shape of 12 magnets, with the armatures in a ring, forming the rim of the fan itself. A rotary pump taking 60 watts is also driven by a small Crocker-Wheeler motor and worm gearing. Small six-cell batteries are also shown driving electric motor for sewing machines. As regards cost, the large primary battery costs complete about £16, and the whole electric light installation, with the exception of artistic fittings, would be almost exactly £100. The first cost is thus within reach of country householders. It may be interesting to add that besides the installation at Victoria-mansions, there is a similar one in a private house at Staines with a set of accumulators supplying 12 30-volt 8-c.p. lamps, and others at Eastbourne and Horsted (Sussex), while a primary battery installation erected some time back in Park-lane, St. James's, has recently been fitted with sets of accumulators with satisfactory results. Messrs. Merryweather are exhibiting a pump driven by the Weymersch batteries, and Messrs. Blackman keep one of their electric ventilating fans in motion at their City offices by the same means.

ON AN ELECTRICAL PARCEL EXCHANGE SYSTEM.*

BY A. R. BENNETT, M.I.E.E.

The congested state of the streets in many of the large towns—notably in the City of London—invites reflection as to whether it is not to possible to devise means by which vehicular traffic may, to a certain extent, be diminished. To avoid absolute blocking of the thoroughfares it is now necessary to forbid the collection or delivery of goods in certain localities during business hours, and trade suffers under such restrictions, while warehouses have to be of larger capacity than would be needed were the free receipt and despatch of goods permissible.

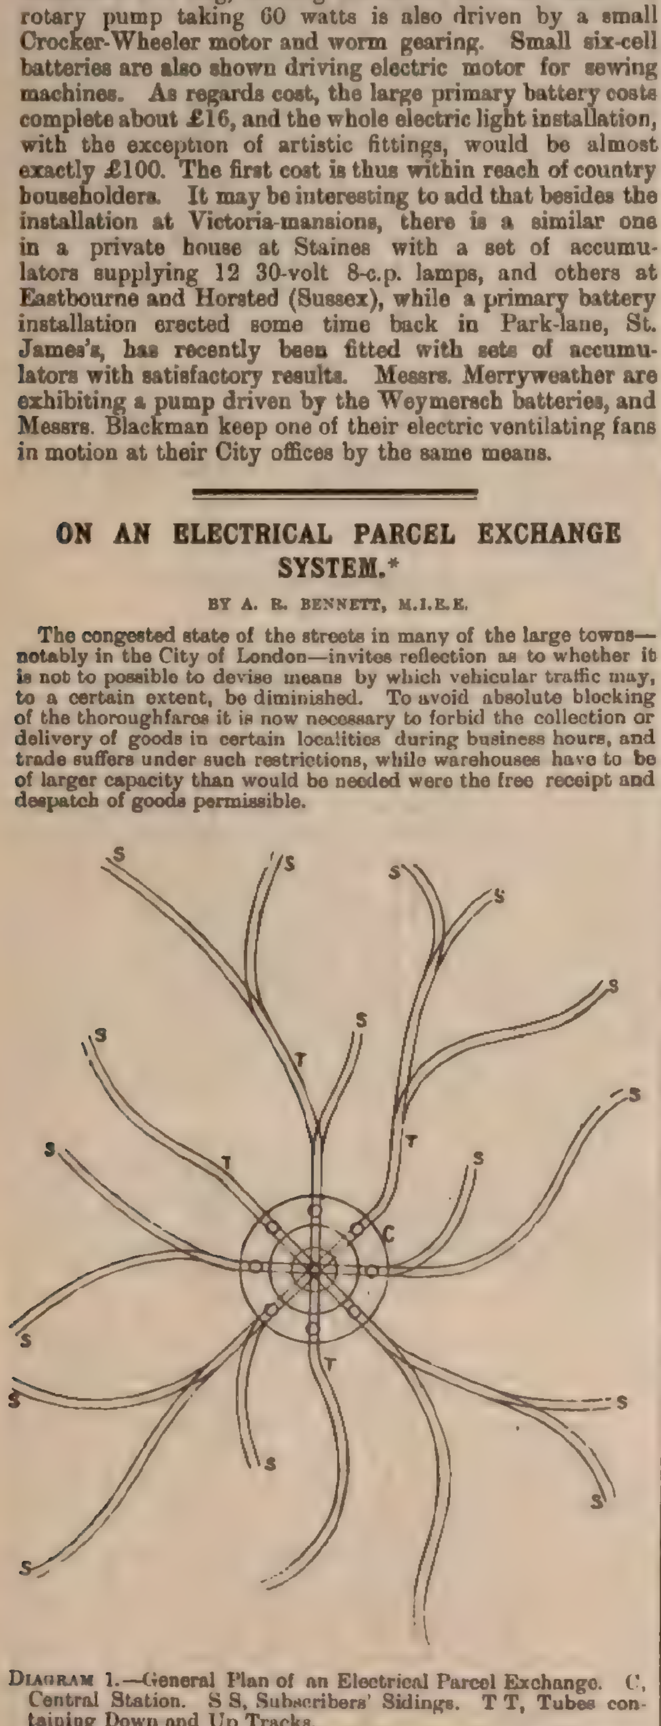


DIAGRAM 1.—General Plan of an Electrical Parcel Exchange. C, Central Station. S S, Subscribers' Sidings. T T, Tubes containing Down and Up Tracks.

Even if a means could be found for the handling at all times of comparatively small pack[illegible] the boon would be no inconsiderable one; [illegible] the vi[illegible]e ground in this direction I have [illegible] the telephone [illegible]hange idea [illegible]changed be[illegible] any num[illegible] apart th[illegible] situa[illegible]

I propose to effect this by means of a number of miniature electric railways, radiating from a central station, and having branches or sidings into all the buildings to be served. The general plan of such a system is shown by Diagram 1.

The railways would be laid in tubes of a rectangular section and so arranged that the down track would occupy the lower, and the up track the upper, portion of the tube. To permit of examination and repairs, the tube should be large enough to allow of a man or boy creeping through, and in order to afford space for this the rails are laid, not on cross sleepers, but on brackets fastened to the walls of the tube. During idle hours the full height of the tube would thus be available for the passage of workmen. The arrangement is shown in Diagram 2. In order to render the rails useful as conductors they are insulated.

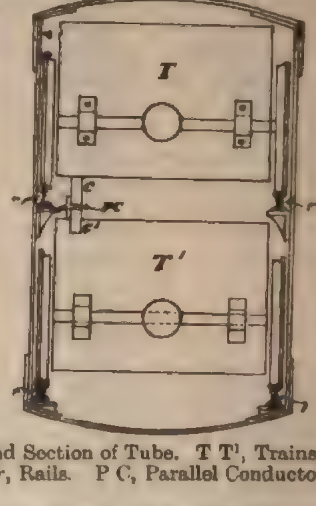

DIAGRAM 2.—End Section of Tube. T T[1], Trains. c c[1], Collectors. r, Rails. P C, Parallel Conductor.

On the rails would run trucks propelled by electromotors deriving their current either from one of the rails or from a separate parallel conductor. On the down journey a truck would gather current by a collector pressing on the under, and on the up journey by one pressing against the upper surface of this conductor, separate collectors being provided and connected to the motor in such a way that a truck could not be made to travel in the wrong direction. If on the down track, it could only obtain current through its upper collector, which would propel it always away from the central; if on the up track, its lower collector would only be operative, and this would always move it towards the central. There are several ways of attaining this end. Collisions between meeting trucks would consequently be impossible. A side section of the tube, showing passing trains, is shown in Diagram 3.

The tubes may be of any size, but I have taken 2ft. wide by 3ft. high as a suitable one. This would permit of trucks 20in. wide by 14in. deep being used. Their length might be considerable, but it would be regulated by the radius of the curves. Supposing 48in. were found practicable, such a truck would contain 13,440 cubic inches, and so be available for pretty large packages. In order to obtain a deep, unbroken box, it is necessary to place the wheels at the ends; and, to get as flexible a wheel base as possible, the wheels should have side play. The electromotor is mounted on a separate carriage, and coupled to the truck, as shown in Diagram 4. Only one end of a truck is supported on wheels, the other resting on the motor-carriage by means of a pin which drops into an eye. Each truck would be fitted with such an eye, so that when a train consists of more than one truck, the coupling-pin of each supplementary truck will drop into the eye of the next. If the wheels are given side play, a very flexible train, like that shown in the diagram, capable of traversing short curves, would result. To prevent bearing down when heavily laden, each truck may be fitted at its coupling-pin end with a pair of unflanged wheels or rollers that will rest on the rails without increasing the rigid wheel base. To secure the adhesion necessary for steep gradients, the wheels of the motor may be coupled, or each pair driven by a separate belt from the motor pulleys.

The central station would be established in a suitable locality. In a large town there might be several stations, connected with each other by one or more sets of tracks, just as telephonic switch-rooms are connected by junction wires. The central station would contain the engines and dynamos for generating the electricity required for working the system, and it might also be utilised as an electric light generating station, or a telephone exchange, since the tubes laid for the parcel exchange service would serve admirably for containing and distributing conductors and wires.

At the central station a turntable or other device for the interchange of trains between the tubes would be provided for each tube. These turntables would communicate with each other, either direct or by means of a central turntable, so that a free interchange of trains between the tubes would be secured. Each tube and turntable would be worked by an operator. The turntables would be in two stages to accommodate the down and up tracks, between which traffic would be exchanged by altering the level of the tables by means of hydraulic jacks. Diagram 5 gives a general idea of such a system. Empty or lying trucks would be stored in siding tracks built one above the other, and reached by [illegible]ing the level of the turntables.

[illegible]nnection with the premises of subscribers to the system would

be made by short spurs or sidings diverging from the nearest main tube. At the junction of the branches with the main tracks switches similar to ordinary railway switches would be placed, and controlled by the operator at the central by means of electro-magnets. These switches may, be arranged in various ways. They may be kept in position for through main-line traffic by means of springs or permanent magnets, and be shifted to connect with the sidings by a current sent from the central, resuming their normal

Elevation of Train with Three Trucks.

Diagram 7.—Subscriber's Siding. Side View.

Diagram 8.—Subscriber's Siding. Plan.

position as soon as the current ceases; or they may be wrought entirely by electricity, a current of one sign shifting, and one of the opposite sign replacing them.

The operator will, of course, require to find and work any switch with certainty and rapidity. I propose to enable him to do so by the arrangement shown in Diagram 6, although several other methods, requiring fewer conductors, could be devised. One pole of a battery or dynamo is joined permanently to an outgoing conductor, which traverses the whole length of the tube. At each switch a branch is taken from this conductor, which, after passing through the electromagnet controlling the switch, returns to the central, and is there taken through an electromagnetic indicator, which may resemble a railway semaphore signal in appearance, and a contact-maker, to the other pole of the battery. By closing any of the contact-makers, the operator can put over any of the siding switches, and the indicators show him that the current is passing. In the diagram one switch is shown over and the semaphore indicating a clear road for that siding. It might be arranged to show him not only that the current is passing through the coils of the electromagnet, but that the armature has actually been deflected and the switch put over.

The sidings into subscribers' buildings consist of down and up tracks one above the other, but when space is available these are caused to diverge after entering the building, and ultimately to meet in one track, so that trains may be shifted from the down to the up track without lifting them off the rails. Diagram 7 illustrates my meaning.

The parallel conductor on the down track need not be carried into the subscriber's building, but may be stopped short within the tube, and the train allowed to finish its journey by the momentum it has acquired. If the conductor were continued to the end of the track there would be waste of energy and danger to the motor in the event of delay in attending to a truck on its arrival.

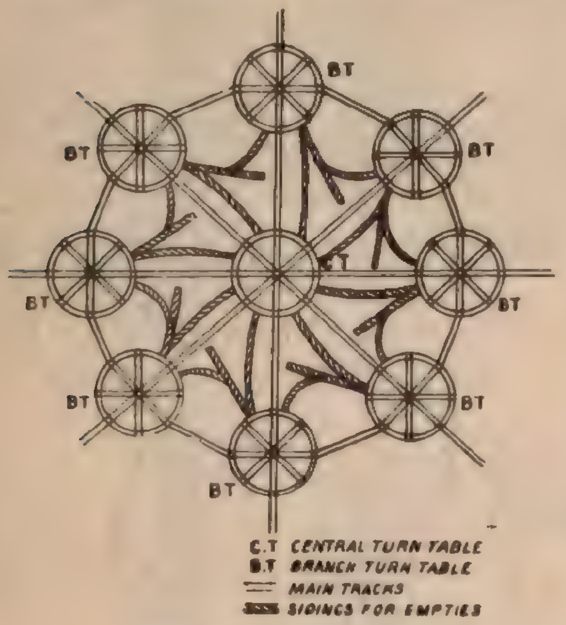

DIAGRAM 5.—Plan o Turntables.

On entering a subscriber's building, a train would have its speed reduced, and finally be brought up by the axle engaging with a hook attached to a weight or spring, or a projection on the truck could depress triggers, which would rise again after its passage and prevent any running back due to rebound or gravity. Such triggers could be electrical contacts, and be made to signal a train's arrival to any part of the subscriber's premises and to the central station. Similar stopping devices would be necessary at the central station to prevent arriving trains over-running the turntables. The subscriber's siding would terminate in an elastic buffer, or stop-block, which would finally bring the train to a stand.

After leaving the main line, and getting well into the siding, a train could be made to break the circuit of the return conductor operating the switch by passing over one or more trigger contacts. The semaphore arm at the central would thereupon rise temporarily and ring a bell, notifying the operator that the train was safe in the siding, and that he might clear the switch for other traffic. Such triggers, if made workable in the down direction only, could be arranged to prevent a train running back and fouling the main line. Such trigger contacts are indicated at T in Diagram 6.

In order to keep traffic circulating, it is necessary that the operator shall be able to follow the progress of all the trains in motion in his tube, so that the position of each and of any accidental stoppage may be known. This may be accomplished much in the same way as that proposed for operating the switches. One rail of a track is in continuous electrical contact throughout. The other is divided into insulated sections of any desired length. If a battery is permanently connected to the continuous rail, and the sections joined to its opposite pole by means of return wires, in the circuit of which electromagnetic semaphores or other indicators are included, the progress of a train will be traceable throughout its whole journey, for, as it short-circuits the rails, the semaphore arms will successively rise to "danger" as it passes from section to section and fall to "line clear" behind it. The failure of a train to enter any siding will be revealed, as its presence on the section beyond will immediately be apparent. The plan is illustrated by Diagram 8.

Should a train, through any accident short of disrailing, stop in the tube, the semaphore of the section it is on will remain continuously at danger, and the operator will know that such a stoppage has taken place, together with its position, and take steps to remove it. For instance, he could send an empty truck forward, the speed of which could be reduced to a minimum as it approaches the disabled train by modifying the amount of the propelling current, until it strikes against the disabled vehicle; then, full current being turned on, both trucks could be forwarded to the consignee or shunted at the next convenient siding. The owner of that siding could be requested by telephone, if so connected, or, otherwise, by a note placed in the empty truck, to couple the vehicles together and return them to the central on the up track. A stoppage on the up track would be dealt with by bringing a truck out of a siding lying beyond and causing it to push the disabled one into the central.

Having explained how the down-line switches are managed by the operator, I shall next describe how he can be given control of

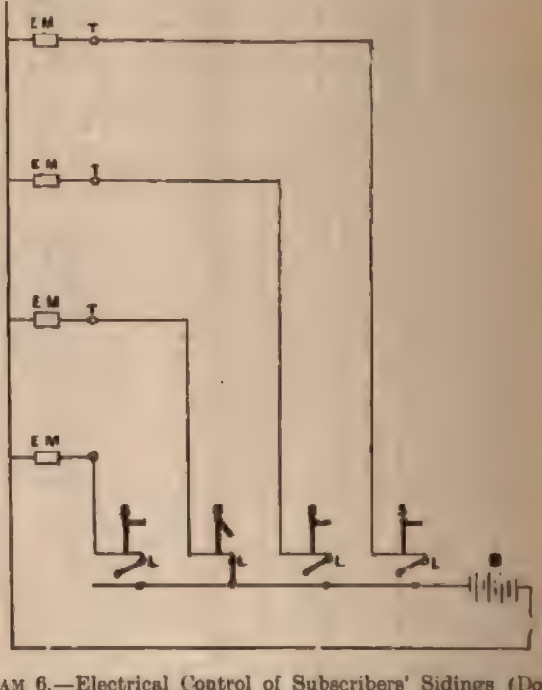

DIAGRAM 6.—Electrical Control of Subscribers' Sidings (Down). B, Battery. E M, Electromagnets Controlling Switches. S, Indicators. L, Circuit Closers. T, Contact Breakers.

the up line ones, too, as it would never do to allow subscribers to send trains into the tube at will.

A branch from the parallel conductor carrying the propelling current is taken into the subscriber's premises on the up track for a short distance, so as to permit of the collector of at least one truck being placed against it, but the portion so taken in is not in permanent electrical connection with the main portion of the conductor, but is effectively insulated from it until the operator at the central station is ready to admit the train to the main line. At the entrance of the tube the up track is obstructed by a projection from the armature of an electromagnet, the projection being of sufficient solidity to resist any attempt to push the train past it. The electromagnet is in circuit with a conductor forming part of a system resembling that which controls the switches on the down line. By using reversed currents the same set of conductors might be made to operate the down-siding switches, and these up controlling electromagnets; in any case, the same outgoing conductor would serve for both purposes. The armature of the electromagnet, when attracted by a current from the central station, removes the obstructing projection, and completes a connection between the main parallel conductor and the portion, hitherto insulated, within the subscriber's premises. If the collector of a truck is pressing against the conductor when this takes place the motor at once obtains current and enters the tube. The up siding joins the up main line by a switch, which, like catch-points on a railway, is opened by the wheels of the truck itself, so that after the operator has started a train no further control is necessary until it reaches the central. As soon as the train reaches the main line it begins to operate the up semaphores at the central, and the operator again blocks the siding.

When starting a down-line train, the operator at the central places the train at the entrance of the tube so that the collector of at least one of the motors presses against an insulated section

of the propelling-current conductor. If the consignee is connected by telephone or electric bell, the departure of a load for him is duly signalled, and as soon as the down line is sufficiently clear of previously-despatched trains, as indicated by the semaphores, the operator admits current to the insulated section of the conductor, and the train enters the tube. The switch of the siding it is intended for being set, the trains turns into it and signals the fact to the central by breaking contact at T, Diagram 6. The operator thereupon takes off the current, and the switch resumes its normal position. The train runs into the subscriber's premises, where it is gradually brought up, and where it announces its arrival by ringing bells, or otherwise. The load is taken off, the train transferred to the up track, and when it is desired to return it to the central, either with a new lading, or empty, it is placed at the entrance of the tube with the collector against the insulated section of the up propelling-current conductor. The operator is advised by signal that a train is ready for despatch. When he has a clear line he works the electromagnet, which removes the mechanical obstruction, and at the same time gives the motor current, and the train runs up to the central, where its motion is gradually arrested. If the load is consigned to the central, the operator turns the truck or train into the siding assigned for such traffic; if addressed to another subscriber, he transfers it to the down track of his own tube, if the consignee's siding is served by it; if not, he forwards it by means of his turntable to the operator who works the tube it is destined for. So, when one subscriber sends a parcel to another, he despatches it, in the first instance, to the central station, where the operator re-forwards it as required.

Should a truck by mistake be delivered to the wrong siding, the subscriber has only to transfer it to the up track and return it to the central.

Although each subscriber could advantageously be connected, telephonically or telegraphically, with the central, such a means of communication is by no means necessary. Trains, as already stated, would announce their own arrival in the subscribers' premises, and if subscribers would place trains on the up line ready for departure, the operator could withdraw them when convenient without troubling the subscribers further. It would be easy to make a rule for the operators to tap all or particular sidings at prescribed intervals during the day, and so withdraw unannounced traffic. The subscribers could be supplied with empties during the night or slack hours of the day without any attendance on their part. Automatic working could be carried further still, for it would not be difficult to arrange to unload trucks sent into subscriber's buildings, and afterwards withdraw them as empties, without any personal attention. The loads could be tilted off, and the truck, when clear of the down-propelling current, run down an incline and through cross-over points to the up track, where it would find the up-propelling current, and immediately commence its return journey to the central. Thus, a man's coal cellar might be filled in the night by a succession of such automatic trucks.

If desired, the starting levers at the central could be interlocked with the levers controlling the siding switches, so that a following train could not leave until the switch set for the preceding one had been restored to its normal position. Collisions between following trains could be prevented by an automatic block, such as was devised by Jenkin and Elliott and Ayrton and Perry for telpherways, by which the second train loses its propelling current if it approaches the preceding one too closely. These precautions would, however, tend to restrict the capacity for traffic, and, as collisions would not endanger life, I am inclined to think that strongly-built trucks, with good elastic buffers, and perhaps extra deep flanges to the wheels to prevent disrailing, would constitute sufficient safeguards against damage to goods arising from an occasional collision. The operators would not allow two trains on the same section simultaneously, and if the sections are 100 yards in length, I contemplate the possibility of a pair of skilful operators, one for the down, the other for the up track, keeping 34 trains circulating in a tube a mile in length—17 down and 17 up. The various control movements are but momentary, and they would only have to be timed in accordance with the indications of the semaphores. At eight miles an hour, 17 sections to the mile would give nearly half a minute between each train.

The body of the tube, if of metal, could constitute the return for the propelling current. For signalling the progress of trains, one rail of each track might form the outgoing conductor, while the returns could consist of small wires—No. 18 gauge would be ample—made up into cables. One outgoing conductor of No. 12 gauge could carry all the current for operating the siding switches and block electromagnets, the returns being No. 18's cabled. The number of conductors would dwindle as the distance from the central increased, and as they would be small and cheap, the outlay for them would not be considerable. Of course, the various switches and semaphores might also be worked off the parallel conductor supplying the motors, as shown in Diagram 3.

For inspection and repairs a special form of truck or platform, on which a man could crouch or lie, would be provided. The motors of these whould be under the control of the men using them, and they would be fitted with brakes, incandescent lamps, and telephones for communicating with the central.

Although the proposal for a system of this nature may appear a little startling, its details, as I have sketched them, comprise no device that has not been thoroughly tested in the telegraph and signalling departments of the Post Office and railway companies, or in connection with electric traction. Mr. Preece, many years ago, employed electromagnetic semaphores such as I propose. The shifting of switches and blocking by electromagnets has been rendered familiar by the labours of Spagnoletti, while the picking up of current has often been demonstrated, notably on the City and Southwark Electric Railway. It may, consequently, be confidently asserted that the plan would work, and work well.

Whether such a system would pay is another matter. If constructed specially and solely for parcel work, probably it would not, although the surprising developments of the last decade scarcely justify us in assigning limits to the possible developments of the next; but I assume that the construction of subways beneath all the chief thoroughfares of large towns, for the purpose of containing electric light and power leads; telephone wires; pipes for gas; water, fresh and salt; hydraulic and pneumatic tubes; and, perhaps, oxygen or ozone to supply our homes with mountain air, together with other possible adjuncts of our complex civilisation, will shortly become an absolute necessity. A beginning in that direction has already been made by limited companies in some of the American towns, and we must sooner or later follow suit. Then, when that time arrives, an electrical parcel exchange could be carried out economically and effectively as part of the scheme. I look forward to a time when our footpaths and carriageways will be laid upon the lids of huge boxes, through which, perhaps, in addition to the various fittings already named, will be carried well-lighted footways, affording crossings and short cuts for passengers at congested spots.

Supposing, for the sake of argument, that the scheme is financially practicable, its many uses will, I think, be readily admitted. What an aid it would be, for instance, to the postal service were St. Martin's-le-Grand connected by such tubes with the principal post offices in the City and West-end. The telegraphic department at present derives great assistance from pneumatic tubes, an inch or so in diameter, through which crumpled-up telegrams are forced in indiarubber balls. If letter and parcels could be interchanged in a similar manner, deliveries could be both expedited and multiplied, and the capacity of the department generally increased. Parcel-post hampers could be despatched to, and received from, the great railway stations in a minute or two, and the mails of subscribers to the exchange system could be delivered without the aid of postmen, while such subscribers would be able to despatch letters and parcels, together with telegrams and the money to pay the charges thereon, straight to the chief post office, so saving labour and delay at the branches. Such a system would form the first step towards telegraphing, or rather wiring, matter.

Apart from the post office, many uses suggest themselves. Parcel receiving offices and great despatchers of small packages, like the Co-operative Stores, Whiteley, and others, would find direct connection to the railway stations, and with other business houses, an important boon. Buyers could telephone for samples and patterns of all kinds and obtain them almost immediately. Hotels and restaurants could telephone for, and receive, in a few minutes supplies they may run short of, and enable their customers to choose wine, not only from the cellars of the establishment, but from those of every wine merchant on the system. Cooks at private houses could not only telephone for a leg of mutton, but have it ringing a bell in the course of a minute or two to announce its arrival. The story of the doctor prescribing by telephone for a baby whose cough he had listened to by the same means is well known. A friend of mine suggests that, with the parcel exchange system, the mother could improve on that by sending the baby bodily to the doctor, *via* the central station, and receiving it back with a bottle of medicine in its fist and a mustard-leaf on its chest.

Discussion.

Sir Frederick Bramwell said the author had very well thought out the difficulties attendant on such a system as was proposed, and, so far as he could see, he had overcome them all. The only question was, would it pay? He had had some experience in tunnelling, and he believed the tube or tunnel could not be made for less than £13 to £20 per lineal yard. For his own part, he should be very glad if such a scheme could be brought into operation.

Mr. Binnie said this tunnel would take up at least 4ft. by 2ft. under the roadway, and, therefore, in order to introduce this system it would be necessary to shift the whole of the existing mains. The difficulty of making the house connections would also be very great, and he did not see how the work would ever pay as a commercial undertaking. The idea might be worked between the central and branch stations in London, and he had no doubt the Post Office authorities would introduce such a system before long.

Prof. A. C. Elliott thought the only obstacle was that of cost. When the electric light was first introduced, people said it would not be successful because of the cost. In spite of this, however, it had come into fairly general use, and if there was found to be a real necessity for an electric parcels exchange, the difficulty of cost would likewise be overcome.

Mr. Greathead, while admitting the advantages which would be derived from such a system, thought the time was somewhat distant when they could have a complete system of subways such as would be required to bring the scheme into operation.

Mr. Bennett said he had considered this question of subways, and he found that it would be necessary to make a clean sweep of the existing mains and begin over again. The Post Office would soon have to adopt some such system to meet their requirements, and they must be the authorities to initiate the scheme. The parcels post was growing, and a small army of men and mail carts were employed in the transmission of the parcels.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 months
United Kingdom............	3s. 3d.	...	6s. 6d.	...	13s. 0d.

THE GROWTH OF ELECTRIC LIGHTING.

Quite recently the *Times* had an excellent article to show that the progress of electric lighting in England, and especially in London, was very favourable, even when compared with the progress in the States. One point in the *Times* article seems to have struck some persons as hardly correct. The slow progress after 1882 has usually been attributed to Chamberlain's Act of that year. The *Times* says not so, but to the fact that electrical knowledge was not sufficiently advanced to give what was required. Mr. Massey rather supported the contention of the *Times*, while Mr. Crompton, in a long communication in the issue of last Saturday, waxes somewhat indignant that anyone can imagine the fault to be anywhere but in the Act of Parliament. After all, any discussion upon the point can be of no earthly value. Opinions differ, and many people incline to the view that much may be said for both sides, and that each is partly right and partly wrong. So far as electric lighting is concerned comparisons are odious, and comparison with American progress especially is not worth the paper it is written upon. The conditions existing in the two countries were and are so diametrically different that there might be plenty of incentives to install one artificial light in one place, while there exists quite as strong an incentive to install a different artificial light in another. A town that has no artificial light, or where gas is from 10s. to 20s. per thousand, does not look upon electricity in the same way as when gas is fully installed and costs 2s. 6d. or 3s. 6d. per thousand. It is of little use either to flog a dead horse or to flog a willing horse, and it is of just as little use to attempt to prove that a town in England ought to follow the lead of a town in America, without stating exactly the conditions prevailing at both places.

There is one phase in the history of electric lighting that is never, so far as we know, sufficiently acknowledged by speakers and writers. We have more than once had occasion to ridicule the claims Americans have made for Edison as an inventor, but we are prepared to admit—nay, claim—for Edison, above all men, the position of having first shown that electric lighting on a large scale was practical, and worthy of commercial enterprise. While Englishmen were pottering about—some with this detail and some with that, none, however, troubling about lighting as a whole—Edison was busy working out a complete system, giving due attention to motors, dynamos, mains, and lamps, endeavouring to make every part fit and work smoothly as a whole. It matters not that the dynamos of that time, as compared with the dynamos of the present day, partook somewhat of the nature of leviathans; the New York installation from a central station was a practical success.

[illegible] consideration of the work that Edison did in [illegible]s will go far to prove Mr. Crompton's con[illegible] at any rate, to be partially correct. He

says: "I do not think, however, I shall be contradicted when I state that in 1883, the year after passing the Electric Lighting Act of 1882, our knowledge of the subject was sufficient to enable us to design central stations on what is known as the low-pressure system, which, in all important respects, were absolutely identical with those that have been since designed and carried out, on the triumphant success of which your correspondent so ably comments." On the *Times* side of the question we have quite as pertinent facts. Some ten millions of pounds were asked of the public, the greater portion given, and not twopence farthing spent in lasting work, or work that Mr. Crompton would acknowledge as coming under the head of electrical engineering. Surely, the *Times* might argue, if the knowledge was as great as Mr. Crompton says it was, something ought to have been done by somebody. Large installations were promised, but not executed. It was not altogether a question of money, for the money was forthcoming, though the work was not. Would it not be best, therefore, to shut our eyes as far as possible on the past, and look more closely on the present and the future?

The Government and shipbuilders helped to stem the crisis in the demand for ship lighting, Edison on the other side and the Grosvenor Gallery on this side prevented absolute failure, and now a healthier tone prevails. True it is that from time to time a more or less extensive promoting swindle takes place, but at the present time promoters have to provide something for working capital, and not take all the money subscribed as legitimate spoil.

THE LATE MR. L. J. CROSSLEY.

It is with sincere regret we record the death of Mr. Louis J. Crossley, J.P., which occurred at his residence, Moorside, Halifax, on Sunday last. Mr. Crossley's name is a household word in telephonic circles, he having designed that very successful form of transmitter known by his name as the "Crossley Transmitter." Mr. Crossley was the only son of the late Mr. John Crossley, of Manor Heath, Halifax, and was born in 1842. The following extracts from the special edition of the *Halifax Courier* of Monday last gives a full account of the late gentleman's scientific proclivities:

"It is in the wide field of electrical science, however, that Mr. Crossley has made his name most famous. At the age of nineteen years he began to take a keen interest in electricity, at the same time paying some attention to meteorology, for his work in which he was made a fellow of the Royal Meteorological Society. While residing at Willow Hall, one of his earliest inventions, the Crossley anemometer, was brought out. This was a gauge for the purpose of recording the velocity and pressure of the wind. About the same time Mr. Crossley and M. Brequet, a leading French electrician, took out a patent for what is known as the alphabetical telegraph instruments, of which some thousands were sold. He was among the first members elected on the formation of the Society of Telegraph Engineers, and remained a member up to his death. On several occasions he was requested to bring his scientific researches before that society, but with characteristic modesty he always pleaded business engagements as a reason for not complying. His fondness for yachting led him to make frequent visits to Windermere, across which lake, from the Crown Hotel, Bowness, to the Ferry Hotel, he laid a cable. It may here be mentioned that he became well known at Windermere and Bowness, gave lectures there, and was very popular with the boatmen.

"Mr. Crossley was the first to introduce electric lighting into Halifax on a practical scale. This he did by getting down from London the celebrated Gramme machine which had been used for lighting the Victoria Tower in the Houses of Parliament. This machine was specially procured by him, at his own expense, to illustrate one of his lectures on behalf of the Literary and Philosophical Society. On the day of the lecture the machine had not arrived, and a message came that it could not be got away. His reply was terse and characteristic: 'It must be done; get more men; get special truck.' And the machine was sent. No expense or trouble were, indeed, spared in procuring apparatus when once he had undertaken to lecture on any subject in connection with which such apparatus was required. On this occasion he showed how sounds could be conveyed by means of electricity, and exhibited also the electric light from a window overlooking Harrison-road. He was likewise the first in Halifax to adopt the electric light for commercial purposes, Albion Mills and parts of Dean-clough being fitted with it.

"The announcement of Prof. Graham Bell's invention of the telephone took everyone by surprise. Mr. Crossley, always on the alert, secured the first telephone that came to this country and had it fixed to the wires existing at Dean-clough in place of the Crossley-Brequet instruments, which were then in use. As in the case of the other inventions and discoveries, he was early at work lecturing, in Halifax, Brighouse, Huddersfield, and other places, explaining and illustrating this latest development of electrical science. Finding that the telephone lacked that efficiency which was required to make it useful for commercial purposes, Mr. Crossley set himself to improve it, and ultimately brought out and patented the 'Crossley Transmitter,' by means of which the message delivered was more audibly carried to its destination. One remembers well the early stages in this development, how experiments were made in Square Church and other places, and the delight one experienced on a certain Sunday evening when, going over to Bradford, one heard there the sonorous tones of Dr. Mellor announcing the hymns and preaching in his own church, eight miles away; and when, also, the singing of the congregation could be heard with equal distinctness. The invention proved very remunerative. It was so completely satisfactory that the United Telephone Company, Limited, who held the Bell, Edison, and other leading patents, made overtures to Mr. Crossley, and ultimately gave him £20,000 for his patent."

Mr. Crossley erected one of the best private electrical laboratories in the kingdom, and his death will leave a considerable gap in Northern scientific circles. The funeral took place on Wednesday, and was attended by many friends of the family, who deeply sympathise with them in their great loss.

GERMAN MUNICIPALITIES AND ELECTRICITY.

At home we find when municipal authorities are desirous of starting a central electric light station of their own, or of undertaking similar work, that deputations are sent here and there in a haphazard fashion to make inspections. The result often is that the deputations return home with their minds in a state of chaos, owing partly to inability to understand what they have seen, and partly to the contradictory nature of the information imparted by the representatives of rival systems, whilst it may also happen that the system most suited to local requirements has not been inspected. The authorities at Frankfort-on-the-Maine have, however, inaugurated an entirely novel course, which merits imitation hereafter. They invited representatives from the whole of the municipalities in Germany to hold a "Städtetag" at the Frankfort Electrical Exhibition, the object being not for these gentlemen to talk, but to receive information as to the present condition of the electrical industries, and to see for themselves what can really be done. The invitation has been heartily responded to by

several hundred gentlemen, and the proceedings commenced on the 27th, and were concluded on the 29th August.

With a view to prepare the minds of the municipal deputations for the subject to be treated, Herr Uppenborn compiled a *brochure* of 271 pages, profusely illustrated, under the title of "The Supply of Towns with Electric Current." This enabled the members of the meeting to take a rapid glance at the various systems available, and also gave them an idea of what they would see at the exhibition itself.

The Mayor of Frankfort presided at the meeting, and stated that they had felt desirous of letting their colleagues in municipal affairs see what progress had been made in electricity. The first paper read was by Herr Uppenborn, who dealt with continuous, alternating, and rotary current dynamos, accumulators, arc and glow lamps, electromotors, etc., putting the information which he gave in a popular way, as pure technicalities would not have been readily grasped by his hearers. He also described what was to be found in the exhibition.

In order that practical demonstration might be made of the statements contained in the paper, an inspection was made of exhibits, the meeting being conveniently held in the Victoria Theatre of the exhibition. Herr O. von Miller, the technical manager of the exhibition, acted as *cicerone*.

In the afternoon Herr Andreas Meyer, chief engineer, Hamburg, raised a discussion on the proposed legislation relating to telegraphy and electric installations, in which he dealt both with the general and the technical features of the position. He stated that the ground occupied by streets was the property of the towns, but that in the past the surface had been mainly used, while now the use of the underground portion was more and more required. It was, consequently, necessary to look into the question of subways for the various systems, apart from gas and sewers. The postal authorities in this matter claimed a prior right, and objected to other conductors because of the disturbance of the weak telegraph current by others more powerful. It was rather a pity that Steinheil had discovered the earth return, as if he had not the Post Office would have had return wires, and would not have raised difficulties as regarded electric supply companies. As matters stood, the Post Office was in a position to make itself independent of powerful currents, and should do so. Mayor Becker, of Cologne, who went further into the same question, was of opinion that the laws on the subject were inconsistent.

A banquet followed, and in the latter part of the evening various amusements were attended by the various members of the meeting. On August 28 the proceedings began with a paper by Herr Oskar von Miller on "The Different Systems of Distributing Current for Lighting and Power Purposes in Towns." By means of diagrams, experiments, and the use of non technical language, he imparted much valuable information to his hearers. As regarded the best system of distribution, he said there was no "best system"; it could not be said that one, and one only, should be employed. Local conditions had generally to be considered. To the consumer it did not matter whether he was supplied with continuous or alternating current. The special advantages and disadvantages of one system more or less counterbalanced those of others. The development of all was, however, such that electricity was not now merely a commodity for great cities, but also for small villages, for industrial purposes as well as for use as a luxury. Herr Ross, of the Helios Company, pointed out that the supply of a town with electricity was not so much a question of a system as of finance. The system to be employed depended upon which would be the cheapest according to local conditions. Herr W. Lahmeyer followed with some information respecting the transmission of current from Offenbach to Frankfort, a distance of six miles, which had been carried out by his firm, and which would have been looked upon as impossible a few years ago. Further inspection of the exhibits was then made, and a luncheon was given in the exhibition.

In the afternoon Herr W. H. Lindley, city architect, Frankfort, read a paper on the various systems of electric tramways. He stated that the expenditure for horse traction averaged from 70 to 80 per cent. of the gross reciepts in Frankfort, while with electric traction the cost amounted to from 40 to 60 per cent. He described electric traction by means of overhead and underground conductors and of accumulators. The last-named seemed the best, but it had failed in Hamburg and Brussels. Experiments, however, were being made with accumulator traction on the "Waldbahn," Frankfort. The fault of the overhead system was that it was ugly and required a network of wires in the streets, while underground conductors had the defect that they suffered from floods, short-circuiting, and so on. Up to the present it had not been decided what was the best system, but electric traction must nevertheless be heartily welcomed.

This subject gave rise to some discussion. A representative of Messrs. Siemens and Halske spoke up for the underground conductor system as carried out at Buda-Pesth, whilst an engineer of the Thomson-Houston Company pointed out that 177 out of the 270 existing electric tramways were on the Thomson-Houston system.

The Opera House was visited in the evening, and the assembly concluded by visiting various municipal works on the 29th inst.

THE TELEPHONE.

[The following letter from the Duke of Marlborough appeared in the *Times* of last Saturday. It is interesting as bearing upon the telephonic papers read at Cardiff.—Ed. *E.E.*]

Sir,—Having made a special study of the telephone for many years, both from its connection with pure science as well as its enormous possibilities as a boon to the public, I venture to crave your indulgence for the following remarks. The paper which was read at Cardiff by Mr. Preece on the Paris and London telephone, and the equally interesting paper that followed from Mr. Bennett on a complete scheme for the telephoning of a large town like London, mark an era in the history of this invention, which is destined before long to be as important a factor in our business and domestic life as the telegraph itself.

The reasons why this wonderful invention has so slowly developed in England are probably not entirely known to the public, and, on the eve of a great development which is now likely to take place, it may be interesting to some of your readers to know what these causes have been in the past and what the progress is going to be in the future.

When the telephone was first started in England, and the Post Office proceeded against the United Telephone Company for infringing the Telegraph Acts, it was decided by the Courts that a telephone message was a telegram within the meaning of those Acts, and that no one had a right to use this invention save the Postmaster-General. The Post Office, however, came to terms with the telephone company, and, on consideration of a 10 per cent. royalty on the gross receipts, the Post Office granted to the new telephone company, and subsequently to other telephone companies, licenses of 26 years' duration. These licenses were of the form of all-England licenses, and were not applicable only to particular districts, and the only reservations contained in them were that the Postmaster-General should not be debarred from entering on the telephone business himself, and that the Post Office should have the right to buy up the telephone industry at a valuation at every septennial period. The first septennial period in the license of the present National Company occurred last year, and I brought the matter to the attention of the House of Lords, and pressed the Government to exercise the power they had and undertake they telephone work of the country as a branch of the Post Office. I had many interviews with the late Postmaster-General on this matter, but it was decided that the sum required to establish the industry on a proper and complete system would be so large that the Post Office did not see their way to undertake the work, besides the fact that owing to the ambiguity of the wording of the purchase clause, it was impossible to say whether the Government, if they served a notice of purchase on the "National," would not have been obliged to pay that company the whole three millions which their share capital had amounted to under the various schemes of amalgamation they had carried out with other companies. As matters are to-day, there is a small development of the telephone going on in some of the large provincial towns of England, but the system is inferior and the cost prohibitive. In London the total number of subscribers does not exceed a few thousand, and these are almost entirely in the City. Practically no development of the telephone for social or business purpose

ts, while the price is above the means of the many. In e European towns the telephone enters largely into public In a small place like Christiania, for instance, the whole ness of the place is done on the telephone, as also is the case Stockholm. A report from the Consular service, dated), gives a very full account of the use of the telephone in way and Sweden. The price does not exceed £4 to £4. 10s. year to subscribers. In a town like London we might fairly ect that one in 50 at least would be subscribers among offices, s, and residents.

ne insuperable difficulty, however, has existed besides the e cost of £20 a year which the National Company have been ging to subscribers—viz., that the system has been a single- system of overhead wires carried on poles above houses, the return current between subscribers has been taken by earth. The consequence has been that the telephone has d the patience of everybody from its inaudibility, while the itive system of exchanges and the fewness of these anges have made the delays in "getting through," as it alled, on the telephone simply intolerable. Every one has got a telephone in his house to-day is in open revolt nst the instrument, on account of its irritating bell its subsequent failure to make itself efficient as a means conversation. Now all this is changed when we come he Paris and London telephone. I have heard the tick he watch of the person I was speaking to in the Rue Grenelle from the London General Post Office, and I d have conversed for hours as if I had been in the same n with my correspondent. This telephone is a complete allic circuit with no earth return. The same result is ved at wherever the twin wire is used, and Mr. Bennett's was interesting in showing that it is easy, at a very lerate cost, to telephone the whole of London on the twin- system, and, with the new system of exchange appliances, o away with all the delays in getting through from one on to another. Moreover, it is demonstrable that this can ccomplished at a remunerative profit for a £10 a year sub- ption for the whole of the London district of five millions of bitants. It is much to be feared that the National Company never be able to reduce their rate to a £10 level, as all the ey they paid for patents should be written off this year, their important patents having expired. Further, their system being rely single-wire, with overhead connections, and with no ral scheme for dividing London up into central exchanges, ould be necessary for them to relay the whole of their wires exchanges from end to end before they could extend their em or improve their service to any practical extent.

nother matter of vital importance is to be able to get all a trunk wires underground, and not only free the air from e black monstrosities, but also be able to establish sufficient between central and sub-stations. In order to obtain this ct, it is necessary to go to Parliament for powers for laying wires underground. This is about to be done, and a new pany, which possesses a license from the Postmaster-General, out to promote a Bill before Parliament next session with object of establishing a complete twin-wire telephone service he whole of London on the basis of a £10 a year rental, with a system based on the plan worked out by Mr. Bennett, hat the telephone will be available to everybody for their ness, their shopping, and their social needs. The scheme most interesting one, and, with the possibility of getting he trunk lines underground, the darkening of the air by cables will be completely obviated and done away with. may, therefore, hope before long to realise the plans set at the British Association meeting, and be able from our writing-tables to speak with a friend in his country home, ven discourse with a friend in Paris as to his doings, and convey our social invitations about town without having to e interminable notes and make numberless cab journeys, n to no avail.

HE BRITISH ASSOCIATION AT CARDIFF.

SIDENTIAL ADDRESS BY WILLIAM HUGGINS, Esq.

(*Continued from page 209.*)

w this state of things, in which the masses, though not equal, f the same order, does seem to prevail in many nebulæ, and ve given birth to a large class of binary stars. Mr. See has tly investigated the evolution of bodies of this class, and s out that their radical differences from the solar system in elatively large mass-ratios of the component bodies, as well the high eccentricities of the orbits brought about by tidal on, which would play a more important part in the evolution ch systems. Considering the large number of these bodies, ggests that the solar system should perhaps no longer be ded as representing celestial evolution in its normal form—

> "A goodly Paterne to whose perfect mould
> He fashioned them . . ."

ather as modified by conditions which are exceptional.

It may be well that in the very early stages condensing masses are subject to very different conditions, and that condensation may not always begin at one or two centres, but sometimes set in at a large number of points, and proceed in the different cases along very different lines of evolution.

Besides its more direct use in the chemical analysis of the heavenly bodies, the spectroscope has given to us a great and unexpected power of advance along the lines of the older astronomy. In the future a higher value may, indeed, be placed upon this indirect use of the spectroscope than upon its chemical revelations.

By no direct astronomical methods could motions of approach or of recession of the stars be even detected, much less could they be measured. A body coming directly towards us or going directly from us appears to stand still. In the case of the stars we can receive no assistance from change of size or of brightness. The stars show no true discs in our instruments, and the nearest of them is so far off that if it were approaching us at the rate of a hundred miles in a second of time a whole century of such rapid approach would not do more than increase its brightness by the one-fortieth part.

Still, it was only too clear that so long as we were unable to ascertain directly those components of the stars' motions which lie in the line of sight, the speed and direction of the solar motion in space, and many of the great problems of the constitution of the heavens, must remain more or less imperfectly known. Now the spectroscope has placed in our hands this power, which, though so essential, appeared almost in the nature of things to lie for ever beyond our grasp. It enables us to measure directly, and under favourable circumstances, to within a mile per second, or even less, the speed of approach or of recession of a heavenly body. This method of observation has the great advantage for the astronomer of being independent of the distance of the moving body, and is therefore as applicable and as certain in the case of a body on the extreme confines of the visible universe, so long as it is bright enough, as in the case of a neighbouring planet.

Doppler had suggested as far back as 1841 that the same principle, on which he had shown that a sound should become sharper or flatter if there were an approach or a recession between the ear and the source of the sound, would apply equally to light; and he went on to say that the difference of colour of some of the binary stars might be produced in this way by their motions. Doppler was right in that the principle is true in the case of light, but he was wrong in the particular conclusion which he drew from it. Even if we suppose a star to be moving with a sufficiently enormous velocity to alter sensibly its colour to the eye, no such change would actually be seen, for the reason that the store of invisible light beyond both limits of the visible spectrum, the blue and the red, would be drawn upon, and light-waves invisible to us would be exalted or degraded so as to take the place of those raised or lowered in the visible region, and the colour of the star would remain unchanged. About eight years later Fizeau pointed out the importance of considering the individual wave-lengths of which white light is composed. As soon, however, as we had learned to recognise the lines of known substances in the spectra of the heavenly bodies, Doppler's principle became applicable as the basis of a new and most fruitful method of investigation. The measurement of the small shift of the celestial lines from their true positions, as shown by the same lines in the spectrum of a terrestial substance, gives to us the means of ascertaining directly in miles per second the speed of approach or of recession of the heavenly body from which the light has come.

An account of the first application of this method of research to the stars, which was made in my observatory in 1868, was given by Sir Gabriel Stokes from this chair at the meeting at Exeter in 1869. The stellar motions determined by me were shortly after confirmed by Prof. Vogel in the case of Sirius, and in case of other stars by Mr. Christie, now Astronomer Royal, at Greenwich; but necessarily in consequence of the inadequacy of the instruments then in use for so delicate an enquiry, the amounts of these motions were but approximate.

The method was shortly afterwards taken up systemmatically at Greenwich and at the Rugby Observatory. It is to be greatly regretted that for some reasons the results have not been sufficiently accordant and accurate for a research of such exceptional delicacy. On this account, probably, as well as that the spectroscope at that early time had scarcely become a familiar instrument in the observatory, astronomers were slow in availing themselves of this new and remarkable power of investigation. That this comparative neglect of so truly wonderful a method of ascertaining what was otherwise outside our powers of observation has greatly retarded the progress of astronomy during the last 15 years, is but too clearly shown by the brilliant results which within the last couple of years have followed fast upon the recent masterly application of this method by photography at Potsdam, and by eye with the needful accuracy at the Lick Observatory. At last this use of the spectroscope has taken its true place as one of the most potent methods of astronomical research. It gives us the motions of approach and of recession, not in angular measures, which depend for their translation into actual velocities upon separate determinations of parallactic displacements, but once in terrestrial units of distance.

This method of work will doubtless be very prominent in the astronomy of the near future, and to it probably we shall have to look for the more important discoveries in sidereal astronomy which will be made during the coming century.

In his recent application of photography to this method of determining celestial motions, Prof. Vogel, assisted by Dr. Scheiner, considering the importance of obtaining the spectrum of as many stars as possible on an extended scale without an exposure

inconveniently long, wisely determined to limit the part of the spectrum on the plate to the region for which the ordinary silver-bromide gelatine plates are most sensitive—namely, to a small distance on each side of G, and to employ as the line of comparison the hydrogen line near G, and recently also certain lines of iron. The most minute and complete mechanical arrangements were provided for the purpose of securing the absolute rigidity of the comparison spectrum relatively to that of the star, and for permitting temperature adjustments and other necessary ones to be made.

The perfection of these spectra is shown by the large number of lines, no fewer than 250 in the case of Capella, within the small region of the spectrum on the plate. Already the motions of about 50 stars have been measured with an accuracy, in the case of the larger number of them, of about an English mile per second.

At the Lick Observatory it has been shown that observations can be made directly by eye with an accuracy equally great. Mr. Keeler's brilliant success has followed in great measure from the use of the third and fourth spectra of a grating 14,438 lines to the inch. The marvellous accuracy attainable in his hands on a suitable star is shown by observations on three nights of the star Arcturus, the largest divergence of his measures being not greater than six-tenths of a mile per second, while the mean of the three nights' work agreed with the mean of five photographic determinations of the same star at Potsdam to within one-tenth of an English mile. These are determinations of the motions of a sun so stupendously remote that even the method of parallax practically fails to fathom the depth of intervening space, and by means of light-waves which have been, according to Elkin's nominal parallax, nearly 200 years upon their journey.

Mr. Keeler with his magnificent means has accomplished a task which I attempted in vain in 1874, with the comparatively poor appliances at my disposal, of measuring the motions in the line of sight of some of the planetary nebulæ. As the stars have considerable motions in space it was to be expected that nebulæ should possess similar motions, for the stellar motions must have belonged to the nebulæ out of which they have been evolved. My instrumental means, limiting my power of detection to motions greater than 25 miles per second, were insufficient. Mr. Keeler has found in the examination of 10 nebulæ motions varying from two miles to 27 miles, with one exceptional motion of nearly 40 miles.

For the nebula of Orion, Mr. Keeler finds a motion of recession of about 10 miles a second. Now this motion agrees closely with what it should appear to have from the drift of the solar system itself, so far as it has been possible at present to ascertain the probable velocity of the sun in space. This grand nebula, of vast extent and of extreme tenuity, is probably more nearly at rest relatively to the stars of our system than any other celestial object we know; still it would seem more likely that even here we have some motion, small though it may be, than that the motions of the matter of which it is formed were so absolutely balanced as to leave this nebula in the unique position of absolute immobility in the midst of whirling and drifting suns and systems of suns.

(To be continued.)

ON THE TELEPHONING OF GREAT CITIES.*

BY A. R. BENNETT, M.I.E.E.

A matter which has never yet been seriously faced is how the demand for telephonic exchange connection, which, after the lapse of a few more years, is bound to arise in all large cities, is to be met. As yet, the merest fringe of telephony as it will ultimately be when developed has been touched. A time will come when every shopkeeper and almost every householder will require his telephonic exchange connection.

What is possible in this direction under the influence of moderate rates and a reasonably efficient service has already been demonstrated in certain localities, chiefly in Scotland, where towns boasting of next to no manufactures or staple trade possess exchanges far exceeding in importance those of many English towns of three and four times the population, the principal supporters of such exchanges, after the manufacturers and merchants, being professional men, as doctors, solicitors, and accountants; householders; and shopkeepers, as grocers, butchers, and druggists.

As exchanges so composed continue to exist and increase year after year, it may fairly be assumed that the subscribers get back their rentals in some form or another, and it may likewise be argued that what is profitable north of the Tweed would be found equally so south, if the experiment were only tried—as it certainly will be some day.

Then, when that time arrives, and the householders and shop keepers of London follow the example of, say, those in Galashiels, and come to regard a telephonic exchange connection as necessary to their business as the laying on of water or of gas, a problem will present itself which, although not entirely free from difficulty, will not, in the light of past experience, present any insuperable obstacles.

The efficiency and the readiness with which a large town or city can be telephoned so as to meet the ever-increasing demands of the inhabitants will depend in a very great measure on how the work is laid out and set about in the initiatory stage.

If London were telephoned in the same proportion as Galashiels, it would possess 28,000 subscribers, but that number does not nearly represent the possibilities—far from it. When a city has attained to the size of a nation—for is not London a nation in itself?—it behoves us to look forward. We must certainly anticipate one telephonic exchange connection for every 50 inhabitants in London in time to come—a modest estimate if we consider that there is already one for every 200 inhabitants in Galashiels and some other towns, which are the merest hamlets in comparison—places in which a pistol-shot will carry from the centre to the green fields in any direction. With London's present population of 5,600,000 such a proportion would represent 112,000 subscribers, and as the population increases and the boundaries extend, more and more will grow the demand, until even that great number will appear inadequate and insignificant.

Every villa in the residential districts, every suburban shopkeeper will be on the exchange, and the telephone will supersede in London, as it has already done elsewhere, the butcher's boy, the grocer's lad, and the baker's man at least, so far as the daily calling for orders is concerned—and tend to make us more independent than we are at present of the domestic servant.

As the new generation grows—a generation familiarised from its cradle with the word "telephone," and the idea of conversing at a distance with all and sundry, and, consequently, free from the prejudices and old-fashioned methods which have, in very many cases, deterred their fathers from availing themselves of the new agent—every young man starting in business will order a telephone connection at the same time that he orders his fuel, light, and water, just as a matter of course; and if time is found at all for speculation on such a commonplace subject, it will be devoted to wondering how his steady-going progenitors did without it.

As an indication of how the telephone idea is taking root, I may mention that the builders of a new block of business offices in Manchester propose to put a permanent connection to the Mutual Telephone Company's exchange into each suite of offices, paying the subscriptions themselves, and charging their tenants nothing extra. This is one of the first-fruits of cheap rates.

The possible demand being conceded, the question arises, "Can it be met; and, if so, how?" I answer that it can, and I propose to show how.

The establishment of an effective and popular telephone exchange in a large town, and one that can be added to and extended freely and economically, without pulling down what has already been done, involves the fulfilment of several indispensable conditions.

Firstly.—Speech must be loud and distinct, and privacy of communication complete; and a subscriber's line and apparatus must be adapted equally well to speaking to another across the street or to one 500 miles away. There must, furthermore, be an absence of all disturbing sounds.

Secondly.—The arrangements for connecting the subscribers together, subsequently disconnecting them, and, if required, immediately reconnecting them to others, must be so complete that eight or 10 seconds should be the maximum time occupied within the compass of the largest town.

Thirdly.—The rates must be within the reach of even small householders and shopkeepers, and should not exceed £8 per annum.

Fourthly.—The general design must permit of the addition of new subscribers in every direction and to any extent, without interfering with the work already done.

All these conditions can be complied with. What is necessary to do to meet them can be broadly indicated under three headings.

1. The universal use of metallic circuits, and the absence from the line of intermediate electromagnets and other signalling devices, which tend to damp and deform the electrical vibrations which constitute telephonic speech.
2. The provision of means by which certain and instantaneous communication can be established between subscriber and operator, and between one operator and another.
3. The division of the town to be telephoned into districts or sections not exceeding a square mile in area, each of which is worked from a switchroom placed at or near its centre.

The fulfilment of these necessary conditions is easy, provided the undertakers, whomsoever they may be, are in possession of the right to open the streets of the town and lay their conductors in the same way as gas, water, electric light, and, in some instances, hydraulic and pneumatic power conductors are laid.

So long as the execution of any scheme is subject to the caprice or the blackmailing propensities of individual proprietors, a proper telephonic service, such as London, the first city of the world, ought to possess, will remain an aspiration and nothing more. It has always been a bugbear of telephonists in this country that they have to fix their wires, not where they want them, but where they are permitted to. A British telephone exchange system is consequently, generally speaking, the result of a constant endeavour to reconcile the desirable with the impracticable—a compromise rarely, if ever, satisfactory.

Legislative assistance to the extent of placing the undertakers of telephone exchange systems on an equal footing with the ministers to other public wants is indispensable to the carrying out of a scheme designed, not only to meet the requirements of the moment, but those of a reasonable number of years to come.

I am not one of those who believe that there is no design in the conduct of the universe—that railways and steamboats are because they happen to have happened, or because, Newcomen, Trevithick, Watt, Stephenson, and Symington chanced to have ideas—that telegraphs are because Gauss and Weber, Cooke and

* Paper read before the British Association.

Wheatstone, and Morse, were scientific enthusiasts—that telephones are because Reiss, Varley, Bell, Edison, and Hughes were covetous of fame, fortune, or notoriety.

No! Railways and steamers, telegraphs and telephones, are means adopted by the Great Designer to meet the needs of growing populations to render possible the feeding and clothing of the ever increasing millions—to lay under contribution for their benefit the uttermost parts of the earth. They make the world larger by increasing its capacity for population, and, at the same time, smaller by quickening communication. The means at the command of our fathers a hundred years ago would not suffice to feed the populace of to-day. Famine and pestilence, without such beneficent provisions, would have kept back the multiplication of the human race; a certain stage would have been reached, but, without the new appliances, never passed. The process is still going on, and will not stop at telephones we may be sure. The future has greater wonders in store than any we have so far seen. Some are already casting intermittent scintillations of their brilliance before—just as telegraphs and telephones were talked of ages ago. It has been truly said that the dreams and fairy tales of one generation become the everyday commonplaces of the next.

Starting with the admission that the telephone is neither a fad nor a luxury, but a providential provision for man's use and benefit—a practical, earnest, matter-of-fact instrument, which has come to stay—we may likewise assume that it is not possible to stifle it, to relegate it to oblivion, or even to curtail its natural extension. Sooner or later it will be universally recognised that the general use of the telephone has to be provided for, and the legislative sanction I am now advocating will be granted in order that such an excellent servant may be turned to the best account.

Without such legislative assistance, which, I contend, cannot consistently be withheld, seeing that it is granted as a matter of course to railway, tramway, and other companies, the efficient and economical telephoning of great cities verges so near to the impossible that, during the remainder of my paper, I shall assume that it will be forthcoming at the proper time.

As already indicated, the system of the future for all large towns must be founded upon the use of multiple switchrooms, each serving its own immediate neighbourhood.

All the subscribers' lines will then be short and economical to construct, while the switching apparatus, owing to sub-division, will be simple and cheap. These conditions will enable the annual payments by subscribers to be kept down to a minimum

All subscribers' lines will be metallic circuits. To the British Post Office (in the person of Mr. W. H. Preece) belongs the honour of being the first to insist on the necessity of double wires for telephone exchanges. The Post Office exchanges have always been constructed on that plan, and, until a few months ago, they were singular in that respect, and the only o es in Great Britain to which a British technical man could re r with any gratification. Some of the National Telephone Company's exchanges have not been without merit, but being single-wire ones, their foundations were as quicksand, and no amount of ingenuity expended on the superstructures could compensate for such a radical defect At best, the faults inherent in the system could be palliated, not cured.

So long ago as 1883 I warned the National Telephone Company of the error they were committing in persisting in the use of the single-wire system, and pointed out how it was then possible to change gradually and economically to metallic circuits. The opportunity was lost, and now cannot be regained without sacrificing the greater part of the capital they have expended.

When the Mutual Telephone Company started in Manchester I advised them to have nothing to do with single wires, but to secure privacy and freedom from disturbing noises by using nothing but metallic circuits. The advice was taken, and universal commendation has resulted.

To obtain an efficient service with multiple switchrooms by the aid of the switching apparatus ordinarily used in this country, with its intermediate electromagnets and numerous complications, would be out of the question. A radical departure from existing practice must be made in this, as in other particulars. Fortunately, the way out of the difficulty lies ready to our hand

For a good many years now a system known as the "Mann" has been operated with the greatest possible success in several districts, principally in Scotland. This system is unrivalled in many respects. It enables connections to be obtained with certainty and celerity; it renders easy the task—on some of the older exchanges an arduous and frequently impossible one—of getting rid of one connection and obtaining another. It simplifies and cheapens switching apparatus to an almost incredible degree, and it permits of connections being made through many switchrooms without the intervention of intermediate electromagnets, so that no retardation and indistinctness of speech results. The system possesses other conspicuous merits, but it is unnecessary to enlarge on them here.

In one respect—and in one only—is the "Mann" system apparently more complicated and more expensive to instal than the ordinary. It necessitates the taking into each subscriber's office of a branch from a common service wire, on which all communications with the operators are conducted, and the addition to each subscriber's instrument of an extra piece of apparatus.

But the complication is more imaginary than real, while the extra cost of the service wire and fittings is saved many times over in the switchroom, where an infinity of complicated and expensive apparatus is dispensed with, and where faults, and attendance by skilled electricians, are reduced to a minimum.

The main feature of the system is the service wire already mentioned. One such wire is allotted to every 60 to 100 subscribers, according to the amount of traffic passing. During the busy hours of the day operators are always listening on the service wires, so that subscribers may speak and be heard without any premonitory signals. By means of specially-constructed telephones, weighing but a little over 2oz., attached to the head by springs, the girls are enabled to listen continuously without fatigue, and at the same time keep both hands free for operating purposes. The subscriber, on his part, can at any moment place himself in communication with the operator by depressing a small lever, which has the effect of changing his instrument temporarily from his main line to the service wire.

The mere depression of the lever suffices to secure her attention at any moment, so that mistakes can immediately be rectified and an explanation asked of any delay. The operators have not to do any ringing at the exchange, the subscribers working their own call-bells, thus leaving the girls to perform only the acts of connecting and disconnecting, a feature which greatly contributes to the rapidity for which the system is famed. A deal of labour is also saved by the absence of the ordinary shutter indicators, the putting up of which, after they have been dropped by the subscribers, constitutes a large part of the operator's work with other systems. The general plan of the service wire is shown in Diagram I. The operator's phone is always earthed; those of the subscribers only when their levers are depressed.

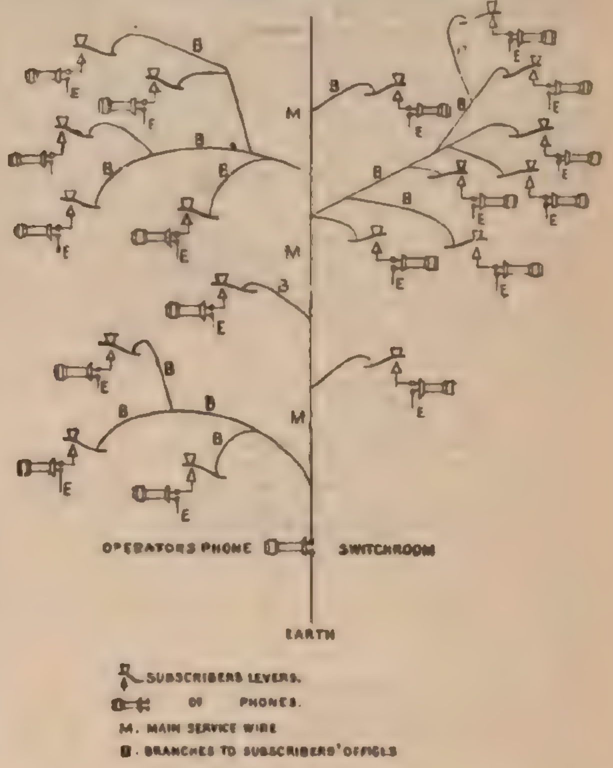

Diagram I.

During the night and slack hours the operators do not listen continually, but the depressing of the subscriber's lever makes a signal which the operator can respond to so quickly that she is ready to listen as soon as the subscriber is to speak.

The marked superiority which this system had shown over every other in Scotland during the years 1883-90, induced the Mutual Telephone Company to adopt it for their Manchester exchange. It was accordingly introduced there in February last, and has already established itself firmly as the best in the estimation of the subscribers.

The experience gained at Manchester has enabled the one objection to the "Mann" system—the necessity of taking an additional wire into each subscriber's office—to be overcome.

After having designed and partially constructed the Manchester Mutual Exchange on the "Mann" system, it occurred to me that it might be possible to convey the service messages between subscribers and operators by means of electrostatic induction between the subscriber's metallic loop and a special single wire run out for a sufficient distance from the exchange amongst each group of metallic circuits.

On arranging the wires and apparatus in the manner indicated in Diagram IV., it was found that such a plan was really practicable. The connections of the subscriber's instrument were altered in such a way that on depressing the lever the metallic circuit (represented by **M** in the diagram) was put to earth through the telephone. The metallic circuit then acted as a single wire of double area, and whether insulated at the switchboard or connected through to another circuit practically formed one plate of a condenser, the other plate or plates of which were any of the adjacent wires that happened to be earthed at their extremities.

It was therefore only necessary to put the operator's instrument in permanent connection with one or more wires runnin llel to the subscriber's metallic circuit for a short distanc any of the subscribers, whose instruments were so fit municate with the operator by depressing their levers

levers were not depressed, the telephones were looped in the metallic circuits as usual, and the operators could neither hear nor be heard.

When cables were used containing 36, or even 72 metallic circuits, it was only necessary to connect the operator's phone to a single wire placed in the centre of the cable, or to the metallic wire on which the operator at the next switchroom is listening. (Diagram V.)

The phenomenon utilised for so conveying the service messages is the one which, under the name of induction, has always been the bane of telephonists, and I believe it has never been turned to a useful account before.

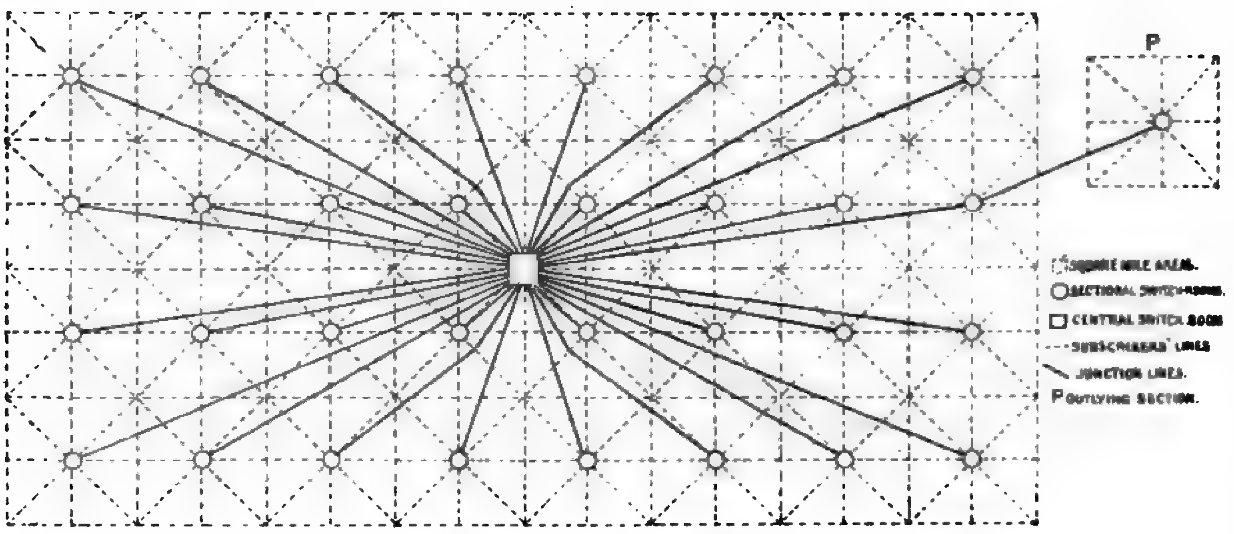

Diagram II.—Plan of Town with One Central Switch Room.

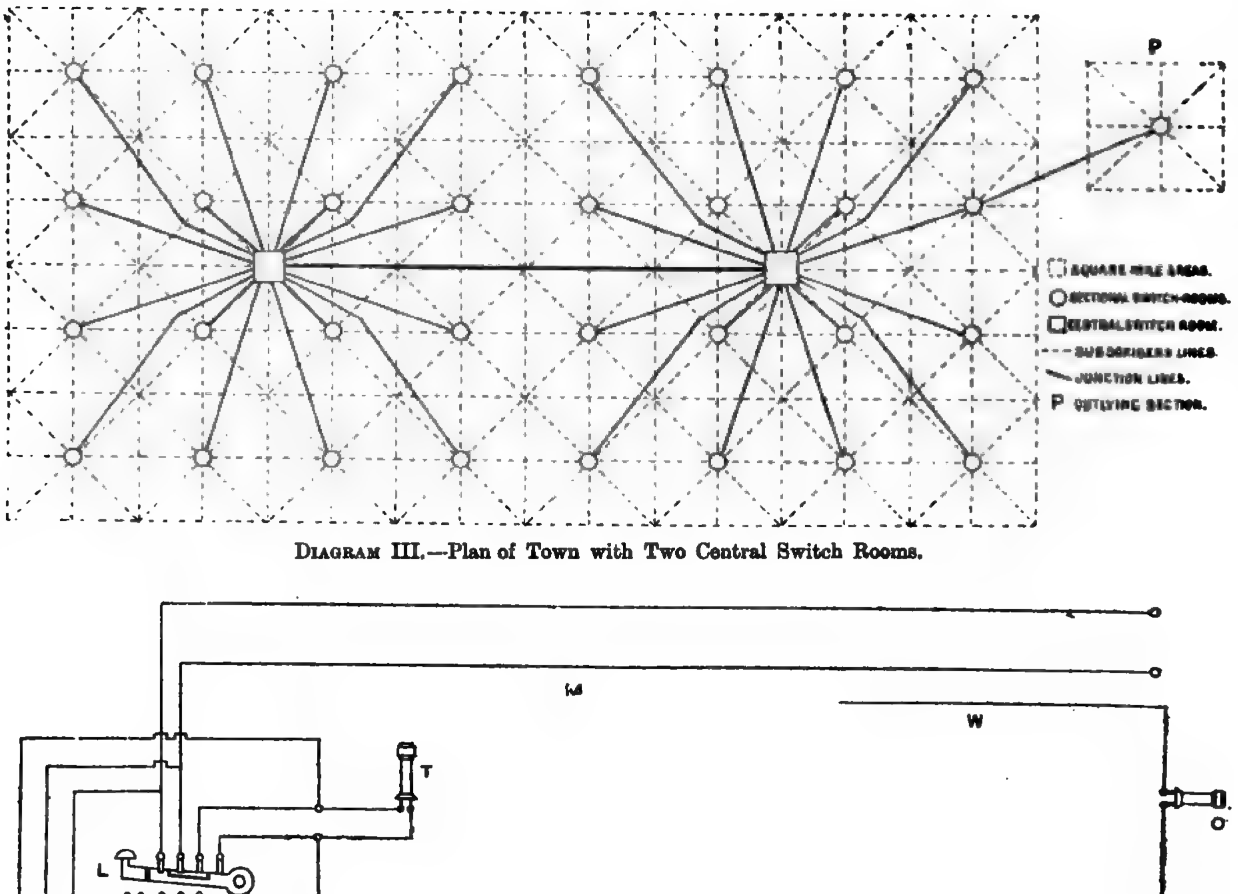

Diagram III.—Plan of Town with Two Central Switch Rooms.

Diagram IV.

M, Subscriber's Metallic Circuit, forming, when lever is depressed, the Subscriber's side of the Condenser. L, Subscriber's Lever, changing his Phone from Metallic Circuit to Earth. T, Subscriber's Phone. W, Insulated Wire, forming Operator's side of the Condenser. O, Operator's Phone.

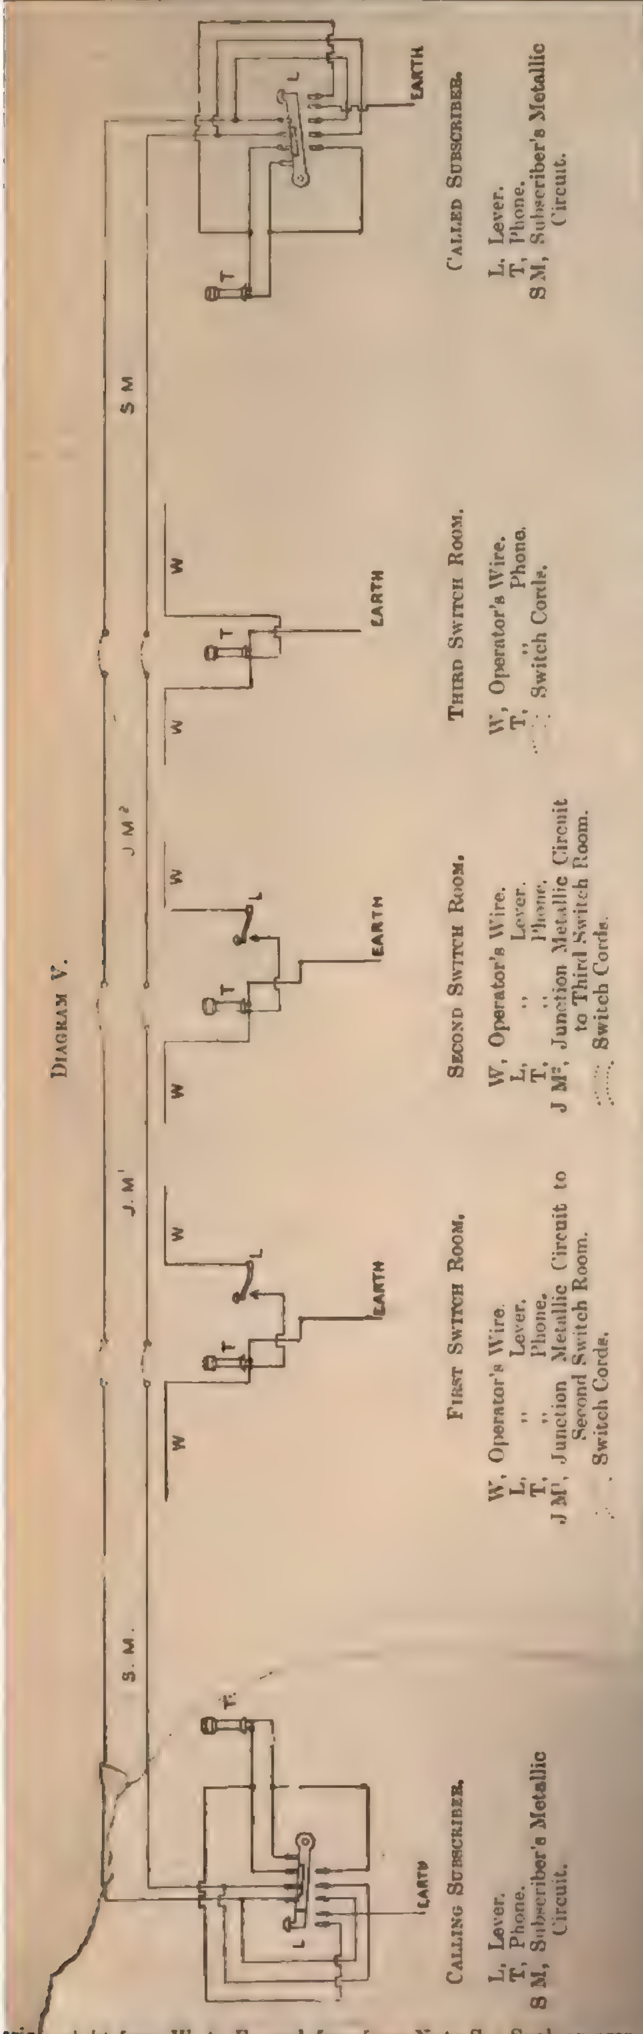
sheathing of the cable, to obtain perfectly good speaking when the metallic loops were earthed by the subscribers depressing their levers.

When a connection has to be obtained through more than one switchroom it is asked for by each operator in succession by depressing a lever which puts her in communication with a service wire.

With this plan it becomes unnecessary to take a separate service wire into each subscriber's office, thereby saving expense and permitting of thinner leads being employed.

I have recently devoted considerable thought to the problem of telephoning a great city like London.

I have taken as a groundwork an area of 32 square miles, mea-



[illegible]ring eight from W. to E., and four from N. to S. Such an area [illegible]uld comprise the greater part of London, from Shepherd's Bush [illegible] Limehouse, and from Primrose Hill to Kennington Oval, and include the chief of the telephonic wealth of the metropolis. Such portions as lie beyond are comparatively poor, and can be dealt with readily by special offshoots from the main system.

Comprising, as it does, the heart of London, such an area would contain the whole, suburbs and all, of any other city in the world. My remarks apply, therefore, to any large town, and the scheme curtailed will fit any town smaller than London.

In considering my plan I have kept steadily in view the conditions I have stated to be indispensable, putting efficiency first and economy second, although, as it happens, I have found the two march well together; so that the working out of my plan, especially if permission to place wires underground is obtained, will be found quite compatible with earning a good dividend on £8 rates. With the Mutual system vanishes the whole costly and complicated paraphernalia of American switchroom apparatus which has been so blindly copied in this country. As an instance of the economy effected, I may mention that in a switchroom fitted for 5,000 subscribers the first cost per subscriber on the American plan is about £3. 10s. for switching apparatus alone; on the Mutual plan adopted at Manchester, the cost per subscriber is about 10s. The difference in cost of maintenance is even more striking, while the efficiency is altogether in favour of the cheaper method.

On the American plan each 100 subscribers occupy 9·9 square feet on the switchboard; on the Mutual plan, the space required for 100 is exactly 5¼in. square. An American switchboard for 5,000 subscribers is 162·5ft. long, and it occupies 325 square feet of floor space. A Mutual board of the same capacity is 44ft. 10½in. long, and occupies 104·7 square feet of floor space. A Mutual board, consequently, costs about one-seventh, and occupies less than one-third of the space of an American. The matter of privacy has been so specially studied that with the Mutual switchboard the operators cannot "tap"—that is, listen to conversation between subscribers—an operation which, with American boards, can be performed continually and continuously without the subscribers being any the wiser.

As already indicated, I propose to telephone any large town by dividing it into sections about a square mile in area. It will not be possible to adhere rigidly to such a division in practice, as parks, rivers, and open spaces will often intervene, and in very active commercial quarters, like the City of London, smaller sections, perhaps as many as four to the square mile, would no doubt be found desirable; but an approximation to the plan will always be possible, and allowances such as these can be made without departing from the principle.

In the centre of each square I would place a switchroom, making thirty-two sectional or branch switchrooms in an area of thirty-two square miles.

According to the configuration and general requirements of the town, I would establish one central switchroom, as in Diagram II.; or two such rooms, as in Diagram III.

This would give thirty-three or thirty-four switchrooms, as the case may be, for the town.

The subscribers in each section would be connected, each by a metallic circuit, to their appropriate switchroom, and the sectional switchrooms would, in their turn, be connected to the central rooms by as many metallic circuits as the traffic passing through them may be found to require. These metallic circuits, joining the sectional switchrooms to the central, I call junctions. When two centrals are used, as in Diagram III., they are connected together by additional junctions. In addition to the junctions, there would be, between the switchrooms, a sufficient number of service wires—that is to say, metallic circuits reserved entirely for service communications between the operators.

The mode of operation may be either the "Mann" plan pure and simple, or the modification of it which I have described. The latter would be the more economical, as it saves a wire to each subscriber.

At the sectional switchrooms, operators would always, during busy hours, be listening on the service wires for orders from subscribers, or from the central; at the central, operators would similarly be listening for orders from the sectional operators.

The subscribers' lines could be distinguished, as is usual, by numbers, each sectional switchroom having assigned to it 5,000 numbers, the first room having numbers 1 to 5,000; the second, numbers 5,001 to 10,000; so on to the thirty-second, which would accommodate numbers 155,001 to 160,000. This would give a skeleton list more than sufficient for one telephone to 50 inhabitants, and would take a good many years to fill up. Further expansion than this we may safely leave to our children to deal with, but the [illegible] switchrooms midway between the old sugges[illegible] method of meeting any dema[illegible] square-mile scheme. Subsc[illegible] change in the number they [illegible] sity of making such cha[illegible] a comprehensive sc[illegible] numbers could be av[illegible] distinguishing name or c[illegible] one upwards.

[illegible] also be known by [illegible] should preferably [illegible] would have to be [illegible] locality of the [illegible] etc. Sections [illegible] be known by

[illegible] served for [illegible] tiguous [illegible] and

The work required to obtain a connection would depend on the locality of the calling and called subscribers, and, while in every case extremely expeditious, would be more so in some cases than in others.

There would be three classes of calls:

CLASS I.—*From a subscriber to another situated in the same square-mile section and connected to the same room.*

The work would consist in the caller depressing his lever and repeating to the operator (who would be always listening) his own number and that of the man wanted, as "20 on 400." With this class of call connection should be effected in two seconds, and a smart operator would manage it in one.

CLASS II.—*From a subscriber on any sectional room to one joined direct to the central.*

In this case the caller would depress his lever and say to the listening operator, "20 on 6,400." The sectional operator immediately depresses a lever, which puts her in connection with a second operator listening at the central, and says, "6,400, Blue 12," Blue 12 being a junction between her board and the central, which she sees at a glance to be disengaged. While speaking she would peg No. 20 through to Blue 12. The central operator, on receiving the message would know that she was required to connect subscriber No. 6,400 to her end of junction Blue 12, an operation which she can perform in one second. Such a connection should be got through in six seconds at the outside.

CLASS III.—*From a subscriber on any sectional switchroom to one on any other.*

This requires an additional repetition. The caller depresses his lever and says to his sectional operator, "6,200 on 19,406"; the operator repeats the latter number to the central, adding the name of an unoccupied junction, as "19,406, Willesden 2," at the same time making the necessary connection on the board. The central operator in her turn depresses a lever which puts her on to a listening operator at the sectional room to which No. 19,406 is connected, and repeats the number with the name of a junction to that room which she sees to be free, as "19,406, Richmond 23," which junction she simultaneously joins to "Willesden 2." The Richmond sectional operator pegs No 19,406 on to junction 23, and the connection is through. The average time occupied should not exceed 10 seconds, and in practice will frequently be less. This estimate is based on the tests described in the Appendix, which were especially designed to ascertain the average time occupied with connections coming under this third class—that is, those requiring the co-operation of three operators. I am so satisfied as to the accuracy of these and many other tests that I should be prepared to guarantee a 10-second service between the most distant sections of an area as large as London if telephoned as described. Experienced operators will dispense with much of the speaking. Thus they agree to work the junctions connecting their respective exchanges in rotation, beginning with No. 1. They remember which they used last, so find it unnecessary to mention a number when asking a connection, both taking the next as a matter of course. They know each other's voices, so that it is superfluous to mention the sectional name. Thus, the last connection would be got through frequently in this way:

Subscriber to first operator	"6,200 on 19,406,"
First operator to second operator ...	"19,406,"
Second operator to third operator .	"19,406,"

all the rest being understood.

The skill often attained by a girl who begins switching at the age of 13 or 14 is perfectly marvellous. When listening on the service wire, some of them can comprehend and execute without mistake two distinct orders spoken simultaneously by different subscribers. When a subscriber gives an order in the usual formula of "No. So-and-so on So-and-so," the girl frequently inserts the first switchplug in the hole corresponding to the first number before the second has been spoken, and the connection is completed by the insertion of the second plug almost before the subscriber has ceased to speak, and certainly before he has time to take his finger off the service lever.

On finishing their conversation the two subscribers depress their levers, and, giving their respective numbers, say "off," as "6,200 off," and "19,406 off." On hearing, the sectional operators remove the connecting pegs and free both the subscribers' lines and the junctions for further connections. The sectional operators could also give the word "off" to the central, thus "Willesden 2, off," and "Richmond 23, off," but this would only be necessary when so busy that the demand for junctions is in excess of the supply, which would never be the case on a well-managed exchange. It usually suffices if the sectional operator in a spare moment notices which of her junctions are still engaged, and says to the central "All off but So-and-so and So-and-so."

Districts lying beyond the 32 square mile area, in which it may be necessary to open rooms, can be attached to the general system and served as rapidly as any of the home sections. Such an outlying square is shown in Diagram II. As in all the others, an operator will always be listening for subscribers' orders, and there will be junctions, together with service wires, to the nearest switchroom within the home area. The service wires will be joined permanently to the service wires from the home sectional switchroom to the central, so that on the outlying operator asking a connection from either the sectional operator or the central, she will be heard by both. If the connection is one with which the sectional girl can deal, the central takes no notice. If, on the other hand, the subscriber wanted must be had through the central, the operator there will give the connection on a junction, which the sectional operator will indicate by a word, as it were, *en passant*. Thus, the calling subscriber depresses his lever and says, "24,002 to 15,008." The outlying operator depresses a lever which connects her to both the home sectional and the central operator, and says, "15,008, Ilford 4." The home sectional girl adds, "Stratford 19," and the central girl knows that she has to give subscriber No. 15,008 on junction Stratford 19, to which the sectional operator has already joined Ilford 4, on which the outlying operator has put subscriber 24,002. The whole can easily be managed in 10 seconds.

An analysis of the movements required to complete a connection by the Mutual as compared with the American system, brings out the merits of the former very strongly, and sufficiently accounts for its superior rapidity.

AMERICAN SYSTEM. *Through One Switchroom.*	MUTUAL CO.'S SYSTEM. *Through One Switchroom.*—Corresponding to Class I.
1. On seeing drop fall, operator turns down table key. 2. Plugs into caller's jack and speaks. 3. Test lines of called subscriber and, finding it free, 4. Inserts plug. 5. Depresses ringing key to signal called subscriber. 6. Replaces table key. 7. Replaces fallen shutter. 8. On receiving ring-off signal removes plugs. 9. Replaces ring-off shutter.	1. On receiving caller's order through telephone (always to her ear) operator tests called subscriber's line, and, finding it free, 2. Inserts plugs. 3. On receiving the word "off" removes plug.
Total 9.	Total 3.

AMERICAN SYSTEM. *Through Two Switchrooms.*	MUTUAL CO.'S SYSTEM. *Through Two Switchrooms.*
The number of movements would be double that for one switchroom, or 18.	1A. Operator A receives caller's order and inserts plug in a junction she sees to be free. 2A. Depresses key and repeats order to operator B, 3 Who tests called subscriber's line, and, finding it free, 4. Inserts plugs. 5. On receiving "off" operator A removes her plugs. 6. Operator B does likewise.
Total 18.	Total 6.

Through Three Switchrooms	*Through Three Switchrooms.*—Corresponding to Class III.
The number of movements would be thrice that for one switchroom, or 27.	1A. Operator A receives caller's order, and inserts plugs, using a junction she sees to be free 2A. Depresses key and repeats order to operator B. 3B. Operator B inserts plugs, using a junction she sees to be free, and 4B. Depresses key and repeats order to operator C, 5. Who tests called subscriber's line and finding it free, 6. Inserts plugs. 7. Operator A receives "off" and removes plugs. 8. Operator C receives "off" and removes plugs. 9. Operator A gives "off" to operator B. 10. Operator B removes plugs.
Total 27.	Total 10.

NOTE.—Movements 1A and 2A and 3B and 4B are simultaneous, one being done with the left, the other with the right hand.

It is evident, therefore, that, roughly speaking, there is about three times the work with the American than with the Mutual system, and that the latter has but one more movement in getting a connection through three switchrooms than the former has through one. The plan I propose is adapted to give a quicker service than the American one, even supposing the mechanically and financially impossibe plan of concentrating all the subscribers lines in one huge central switchroom were adopted. It is this fact that enables me to advocate with the fullest confidence a multiple switchroom plan as the best means of telephoning a great city. The modified Mutual system in combination with such switchrooms solves the problem of how to deal with very large exchanges. It enables the greatest simplicity to be maintained throughout. It contains within itself the principle of indefinite expansion, and the larger the number of subscribers it has to cope with the more conspicuously do its merits shine out.

The size of the switchrooms would be kept within reasonable limits, and the apparatus consequently would be simple and cheap. The largest would be the central, but even this would have to deal with only 40,000 lines when the maximum of 160,000 subscribers came to be reached, allowing the very liberal proportion of 25

ent. cf junctions I apprehend no difficulty whatever in ging 40,000 lines in one room. The floor space required only be about twice that now wanted for 5,000 lines on the ican plan.

rent and other expenses of so many switchrooms may be as an objection, but I do not consider it at all a serious one. apartments would suffice for the sectional rooms; many of would be in cheap neighbourhoods, and all could be top floors ices

nay also be said that the number of operators required would eat; but so it would be with any system, and the wages of score of girls are neither here nor there when the economies wise effected, and the prize to be won by any company a good and cheap service in such a town as London are lered.

h a service would, I believe, produce a circle of between and 40,000 subscribers in the course of three or four years. upposing that London only managed to attain the present of Galashiels within that period, the number would be This, at £8, would mean a gross annual revenue of 000, and, deducting 50 per cent. for working expenses, a venue of £112,000. Capitalised at 5 per cent., the sum ented would be £2,240,000, or £80 for each subscriber cted. How such an amount could be expended I cannot ee. With a switchroom in the centre, or nearly so, of square mile, the average length of the subscribers' lines be only a quarter of a mile. The cost of wires, instruments, witchroom fittings would be £10 per subscriber at the outside. ing each subscriber with another £10 as his share of the cost junction lines and central, there would remain a balance of er subscriber for conduits, labour, and miscellanous expenses. at that I do not know how such a sum could be spent, and I e that after a short experience a subscription of £8 would be unnecessarily high, and capable of substantial reduction. to ensure such a result, the systematic working out of a le plan must be insisted upon. There must be no patching ches, and the first object of the undertakers must not be to money by hook or by crook, but to establish an efficient nge. That done, the rest will follow of its own accord, and ward will be rich exceedingly.

Preece has shown us how efficient telephonic communication established with Paris and other distant towns; and one quence of the adoption of such a system as I have described be that London subscribers would be able to speak from own offices and houses to the offices and houses of subscribers ris. The adoption of metallic circuits in Brussels and many continental towns would bring them also within range. out metallic circuits the scope of long-distance telephoning tricted within much narrower limits; for instance, London ribers cannot at present speak to those in Manchester or pool, except by the aid of special apparatus corresponding to which I would make universal.

success of the Mutual Telephone Company in Manchester e cited as an instance of what is possible with low rates and service. The rate is £5 to shareholders, and £6 to others, the average is very nearly £5. 10s. The exchange comed working on February 28th last with 68 subscribers. On 30th there were 413 subscribers connected, and the net profit month's working for Manchester centre was at the rate of er cent. per annum; on July 31st the number connected was representing a revenue of £2,840, and the profit on the 's working was at the rate of 5·04 per cent. per annum. At me date the amount expended on the Manchester exchange 12,469, scarcely £24. 12s. per subscriber, which sum not only ented the cost of joining up the 506 subscribers, but included ion for future developments on an exceedingly liberal scale. ink, therefore, that there is reason to believe that telephony e both good and cheap at the same time, and that in the it will be both.

APPENDIX.

an existing exchange worked according to Mann's system, perator in ordinary course of business deals with 180 cons per hour, or exactly three per minute, of which about half o be obtained from, or given to, operators at other switch-. On a special trial being made, by several inspectors being an operators' service wire, with instructions to supplement rdinary traffic by demanding connections incessantly, the tor successfully dealt with 357 connections in exactly one She therefore got through 5·95 per minute for 60 consecuinutes, which gives an average for each connection, including quent disconnections, of 10·09 seconds. Of these she completed self, 223 had to be asked from another switchroom, and 42 given to another switchroom. All the usual incidental was properly performed, such as informing callers that the riber wanted was engaged ringing up callers, and notifying the subscriber previously advised as engaged could now d; answering repeated demands from impatient callers for ed or dilatory subscribers; informing operators at other rooms that subscribers wanted could not be had, with the s, and subsequently advising that they were free.

cial tests were made to ascertain the rate at which ctions involving the attention of three different operators sponding to Class III. of the proposed London system) could mpleted and subsequently got rid of. For this purpose a conversation was arranged, each subscriber on being rung ng told: "This is the telephone manager's office; is there my inspectors at your place just now?" Two tests were in each case 20 consecutive connections being demanded with subscribers taken at random from the list, except that only those were selected whose connections, owing to the position of their premises, would have to be handled by three operators. It was agreed beforehand, that if any subscriber called for left his bell unanswered for 60 seconds the experimenter would tell the operator to disconnect and give another. The tests took place during busy hours of the day, and were imposed on the ordinary traffic.

Test A.—Twenty connections were made, but the twelfth subscriber asked for did not answer within the regulation minute, so that only 19 model conversations were held. The first connection was asked at 10h. 1m., and the twentieth was done with at 10h. 19m. 40s. Deducting one minute lost over the subscriber not obtained, the average for the 19 conversations had was 55·8 seconds.

Test B.—Twenty connections were asked for, but one subscriber was engaged, and two others did not answer within the regulation minute; consequently only 17 model conversations were held. The first connection was asked at noon precisely, and the twentieth was done with at 12h. 14m. 20s. Deducting three minutes lost over the three not obtained, 17 conversations were completed in 11m. 20s., giving an average of 40 seconds per conversation. Of the 680 seconds occupied, only 136 were taken up in asking for and making the connections; the balance was consumed in ringing the subscribers called, by their delay in answering, in putting the model question, and receiving the replies which were not always confined to a monosyllabic negative.

ERRATUM.—In Mr. Preece's paper on "The London-Paris Telephone," published in our last issue, in the last paragraph—page 212—the figures 1·8 and 3 should read ·18 and ·3.—ED. *E. E.*

DISCUSSION ON THE PAPERS OF MR. PREECE* AND MR. BENNETT.

Major-General Webber said that in such a paper as they had heard from Mr. Preece they were at a disadvantage, because the reader was naturally tied down by his official position, and did not give to himself or those with whom he was associated—they being public officers—all the credit that they deserved. No doubt many of those present had watched what had been called long-distance telephony, as accounts came out in the public press from year to year. They had seen reports of experiments that had been made between Paris and Brussels, associated with names which he need not mention there; and perhaps they had wondered that during so long a period no great success in establishing long-distance telephony had been achieved at an earlier date. It was owing to Mr. Preece and to those connected officially with the telegraph departments of Great Britain and France, assisted by that great factor the public purse of both countries, that long-distance telephony had been made a success; and that chiefly for the reason that those gentlemen early saw that it was necessary to have a metallic return. Those who investigated the subject in previous years had in view the utilising of existing telegraph lines, all of which had earth returns, and all their efforts were in that direction. The credit of showing that a metallic return was necessary was due to their chief electrician, as also was the inducing of those who had charge of the public purse strings to incur the necessary expenditure to enable it to be done in the way in which Mr. Preece had described. The achievement which Mr. Preece had described was one of the most marvellous public works of this kind that had been undertaken in this country and in this century. As regarded Mr. Bennett's paper, he was sorry it had not been read *in extenso* as it deserved. He also thought that a great many present had not been able to realise the value of what he had brought before them. He had described the Mann system of telephone exchanges, or rather he would have done so if he had had time. The whole question was one that was very much before the introducers of the telephone in this country in 1880. At that time the advantage of a metallic return was well known. But it was a serious question to those who had to find capital for the establishment of telephone exchanges in the towns of Europe to incur the cost of two wires to every subscriber. The cost of one wire was, say, £10 per mile, and the doubling of that for a large system meant a very considerable outlay. He must admit that, being largely interested in that establishment, when he had to give his vote he gave it in favour of one wire and earth returns. The effect of induction and other difficulties had since brought about the conclusion that the double wire was the best. He thought this was the natural result of experience, and he was glad to see that people were going to use this system. But they must also recollect that the Mann system necessitated a third wire, not a third wire to every subscriber, but one between, say, 50 or 60 subscribers; and, therefore, increased expenditure per subscriber was necessary in the shape of capital outlay on lines. While the application admitted at once of the simplification of the exchange room, the complication of lines was ... tain extent increased. The really interesting point in ...'s paper was the discovery—he believed he was ... his (Mr. Bennett's) discovery—that had been poi... Diagram IV. It was a most interesting outco... ns and experience, because, admitting that ... best, this saving in a branch wire int... an important factor in the success of ... did not give credit to one essen... (the speaker) advocated in 1883, at ... out that the great delay in tele... system which had been brought ...

* Mr. Preece's paper on "T... was given in our last issue.

had only started exchanges in America, and had not found out one fundamental error, and that was that all telephone exchanges were worked by the switchroom—that is, the central office—having to call up a subscriber, and it was that which caused delay. But once the public had been educated to follow this system, it was extremely difficult to change them. He advocated the closing of all the offices and starting anew. The success of Mr. Bennett's system was mainly due to teaching subscribers it was their duty to call up their correspondent directly. As soon as they were taught to do that they would get rid of all delay, and as soon as that was recognised in a few exchanges the rest would soon follow. There was no doubt that the double-wire system, together with the essential part of the Mann system, would simplify telephonic work in the future. Mr. Bennett described how the young lady in the switchroom had two little telephones attached to her ears, by which means she was placed in communication with 50 or 60 subscribers, and by which a considerable amount of the switchroom apparatus was saved; but when they came to consider what it would mean to have wires attached to your ears in communication with 50 or 60 persons he must say it was a very serious thing. Mr. Bennett told them that the young ladies had acquired the art of not going mad in a wonderfully short time, and if they began at 15 or 16 they would never have to be sent to a lunatic asylum. He must say that it was a detail to be overcome, no doubt, but it was likely to be problematical. Mr. Bennett told them that this difficulty of facing the demand for telephonic exchanges in large cities like London had never been faced before. He would remind him that in 1880 he (the speaker) laid out the City of London for 200 exchanges, and plans were published at the time.

Mr. Davey said that Mr. Preece, who was responsible for overcoming the difficulties of the London-Paris line, had not told them all the difficulties. He would like to ask Mr. Preece whether one of the great difficulties was not that of sending a message through a submarine cable. He thought a mechanical illustration of assisted induction might serve to rivet on their minds the great benefit which had been derived from what Mr. Preece had told them was the greatest improvement in the system. He had shown them two diagrams, one to illustrate what he (the speaker) might call resisted induction, and the other assisted induction. If they drew two parallel lines and put two geared wheels between the wires and touching them (assuming them to be geared together), and applied force to the periphery of one wheel, it would resist a force which was applied in the opposite direction on the periphery of the other wheel. That was, if they put in an even number of wheels geared together, they had an illustration of resisted induction. But if they put in an odd number they got assisted induction.

Prof. Silvanus P. Thompson said they were greatly indebted to Mr. Preece for his clear description of the London-Paris telephone, and he quite agreed with General Webber that they ought to credit Mr. Preece with a little more than his own modesty had claimed. He and his coadjutors in the General Post Office deserved great credit, not only for the work done in this particular extension of the telephone, but for the work they did years ago—more particularly in Newcastle, when they led the way to the establishment of exchanges on a more rational plan than that which came over from America. They were so apt to think that American electricians led the way—they told them they did, and occasionally they were believed for want of further information. Now the fact was, they (the English) led the world in telephonic work, and not the Americans. Mr. Preece and the Post Office officials at Newcastle established a better way of laying out an exchange than the American plan, and their Scotch friends had still further improved on it. The British Post Office, moreover, had availed itself of still further improvements that had been made in signalling. He had the misfortune to differ from Mr. Preece as to the theoretical working of telephonic circuits, but that did not prevent him from admiring the good work he had done. Mr. Preece had said that he did not know to whom was due the credit of using a shunted condenser. He thought if Mr. Preece would refer to an old work, *Kreller's Journal*, he would find a paper by Helmholtz, about 1850, in which the effect of using a shunted condenser for stopping sparks, or the effects of electromagnetic inertia, was clearly pointed out. He was glad that Mr. Preece had accepted the proposition that retardation due to induction was antagonistic, in a certain sense, to the retardation due to actual capacity. He had told them that a condenser properly shunted could be made to counteract the effects of self-induction. He wished that Mr. Preece would believe that induction could counteract the effects of capacity. The reason why they could telephone through lines having capacity was because of induction. That rather difficult proposition was laid down by Mr. Oliver Heaviside; he (the speaker) found it very hard, and he knew that Mr. Preece had not accepted it. Their attention was drawn to the very pretty mechanical method of illustrating assisted and resisted induction; he would point out that it had been given in Prof. Oliver Lodge's "Modern Views of Electricity." This showed them that the energy was not propagated up one copper wire and down another, but across the medium.

A Member asked Mr. Bennett whether it was possible to reconstruct existing exchanges by substituting double wires for single without pulling them to pieces; or whether it would be necessary to do as they had done in Manchester—viz., make a new exchange altogether? In that case the enormously watered capital of the National Telephone Company, which amounted to about three millions of money, would be absolutely useless. Would the present company be able to put up double wires without producing a loss of capital?

Mr. S. F. Walker congratulated Mr. Preece on the results he had obtained, and asked if he had had any trouble with leakage on the London-Paris line. As to Mr. Bennett's paper, he had long been of opinion that the question of the increase of telephone exchanges must be faced sooner or later. As soon as the monopoly had fully expired there was no doubt there would be an enormous development. Everybody would have telephones if they could have them cheap. But no matter how much branch centres were multiplied, the more the subscribers were increased the more they must multiply their connecting lines; and he thought when they got beyond a certain point the rate must go up or the dividends would go down, unless they could save the increased cost in another way. He was very pleased to find Mr. Bennett tackling the subject. Attendance was one of the biggest charges, and if Mr. Bennett could reduce its cost in the way he suggested, without sending telephonic young ladies into lunatic asylums, he would put universal exchange work several degrees forward.

Mr. Blakesley asked as to Diagram 4, in which Mr. Preece gave a longitudinal section of the line. He had put the telephone at St. Margaret's Bay in shunt and the telephone at Sangatte in shunt. If he (the speaker) understood aright, the St. Margaret's Bay telephone was in shunt when used to London, but when anybody was talking to Paris it was not necessary to shunt it. This was very interesting, but he thought that fact could not be taken as universally true. It would be better that telephones should be in series in other cases. The way to decide whether they should be depended upon certain properties of the cable itself. In Fig. 1 there was some mistake. He supposed Mr. Preece did not mean that the current began to fall or rise suddenly and ended suddenly? It began gradually and reached its maximum gradually. He was very glad Mr. Preece had arrived at the principle of the use of the shunted condenser. He (the speaker) worked out the theory of the condenser in series and shunt circuits in 1884. Prof. Thompson had mentioned that somebody else had used a shunted condenser before, but he did not think they gave the theory of it. Sir William Grove made very remarkable experiments with a condenser, but it was for sending large currents into the primary of a Ruhmkorff coil by means of an electrical machine, and getting extraordinary sparks in the secondary. He knew the effect was produced by the condenser, but he did not attempt to explain it. He (the speaker) would have liked to have made further explanations. The whole thing was very interesting, but it required a better memory than he had to carry the facts of the case in his head.

Mr. Gavey briefly described the system used by the Post Office. It consisted of a metallic loop and signalling arrangements, a small shutter held up automatically by the current, and a small indicating needle. If the renter wanted the attention of the telephone exchange, by pressing a button the shutter fell and the ordinary connections were made. When the renter had completed his conversation, the mere act of restoring the telephones or tubes to the rests sent an automatic current, which, deflecting the needle in the indicator, advised the clerk at the room that the conversation was complete and the connection severed. Mr. Bennett suggested in his paper that electromagnets introduced in a telephone circuit caused trouble. Under certain circumstances, yes. But they could always be so disposed as to cause no trouble whatever. His general experience of the introduction of electromagnets in the Post Office system, with indicators in short circuits, such as were used in towns, was that they had no evil effect. If they were introduced on long trunk lines the effect would be to very much dull the speech, and, perhaps, to render it utterly impossible. But this could always be overcome by using indicators of high resistance and great self-induction, and by bridging them across the line, much as they saw the telephone bridged across in Fig. 4 in Mr. Preece's paper, instead of putting them directly into circuit. When that was done, the effect on the speech was absolutely inappreciable. The rapid telephone currents did not traverse the indicators at all, whereas the slower ringing currents were distinctly felt. The system hitherto introduced into this country had always been to minimise, if possible, the number of exchanges in a town, because if these were multiplied delay was always introduced in putting one exchange in connection with another. With many exchanges the switch clerk had to connect a renter through his switchroom and through one, or perhaps two or three others, and when he was through the reply came that the person wanted was engaged, and all the work was wasted. So that when they could have direct lines all centreing on one exchange, though the cost might be increased, the efficiency of the service was increased also. He would venture to say, therefore, that in all towns of moderate size the most efficient service on the whole would be one that centred the whole of the wires in the town into one exchange. In towns of enormous size the cost of a service of that character would be absolutely prohibitive. Mr. Bennett had indicated one method of multiplying exchanges which was certainly very promising, and might be developed later into a very useful system.

Mr. J. Head said Mr. Preece had shown them that telephone lines of 500 to 800 miles could now be made and worked with perfect success. They were all very much interested in being able to talk from London to Berlin, and so on, but they were most of them still more interested in being able to talk from one part of their own country to another. 800 miles included the most distant parts of that country. Would Mr. Preece's experience encourage him to say that within a measurable distance of time the local exchanges in the country would be so connected as to enable them to talk with their friends wherever they might be in the United Kingdom?

A Member asked what was the distance over which telephone messages could be sent in America.

Mr. Wallace, alluding to the important remark made by Mr. Preece, that in the future all telephone wires must go under-

paper :

ound, said that this would take some time to do, but it must be one of the objects which all persons who wished to construct proper exchanges must have in view. Of course, it could not be done by the National Company without expending a tremendous amount of extra capital, and doing away with practically the only asset they had left out of the money they had spent. Perhaps Mr. Preece would tell them whether it could be done by the Post Office. As to the inter-connection of towns, too, he would like to hear something from Mr. Preece. He thought they might take it that they would be obliged to have metallic returns in the local exchanges, as Mr. Bennett had already pointed out.

Mr. Preece, in replying, said he would take the questions put to him *seriatim*. Mr. Davey hinted that he did not refer to the submarine cable as an obstruction. As a matter of fact he had done so, because he always put the cable as part and parcel of the whole circuit, and when he used the term K he included that. Cables were a very great obstruction, simply because the electrical capacity they possessed bore such a very large ratio to that possessed by the rest of the circuit. They had found that the 23 miles of cable across the Channel had not been a great obstruction. In the case of a proposed circuit between London and Brussels, a cable of 60 miles would prove a rather serious obstacle. Prof. Thompson referred to *Kreller's Journal*. He was a mine of information. If anybody wanted to know the history of any matter electrical, there was the man. If they wanted anything written about the history or the theory of electricity there was their philosopher and friend; and although he had then heard for the first time that Prof. Helmholtz—the greatest living authority—had introduced matters relating to condensers, he would go to his friend and learn all about it in a very short time. Prof. Thompson accused him of not accepting, or of neglecting something. All that he knew was that in electrical matters he invariably accepted truth. If it turned out that he was wrong, he willingly changed his view, but he had seen more nonsense written on that subject of self-induction than any other in the English language, and the reason was that the writers on electricity did not always apply the same term to the same thing. They were not even agreed as to the use of the simple letter L. It was not always used to imply the same thing, and the result was that some of Prof. Silvanus Thompson's friends might have used L to indicate the very reverse of what he (the speaker) did. He would find out from him, and if he was wrong he would withdraw anything he had said. As it was, his paper said that there were conditions where induction favoured the transmission of speech, and that was why they spoke so well. Prof. Thompson had referred to the assistance he (the speaker) had received from the Post Office officials in carrying out those works. He did not believe that in any service in this world there was a finer body of men than in that of the British Post Office. And if there was any branch in which their capabilities came to the front more than another, it was in the electrical branch. They had that day had some remarks from his oldest friend in the Post Office and his ablest assistant—Mr. Gavey—who had charge of the telegraphic arrangements in that part of the country, and there was no part of the country where telephony had been carried out to greater perfection than down there. All the towns of the valleys of South Wales, Swansea, Newport, Bristol, etc., were in direct communication with each other, and all the principles of clear speech had been carried out there in their highest order. In Newcastle, again, there was Mr. A. W. Heaviside, in Liverpool Mr. Edwards, and in London Mr. Cooper and Mr. Brown. The sole object of these men had been to benefit the public service and to show that good work could be done. Prof. Blakesley did not understand Diagram 1. It was an attempt to indicate the appearance of the current as it was received at the distant end of the circuit. For instance, if they sent a current from Ireland to America on the submarine cable, it was recorded by a Thomson recorder, and the line of the recorder was a curve very much like that. He had carried out a heap of experiments in recording telephone currents. They were so delicate that the absolute currents could not be recorded, but by the use of a very powerful primary current and by the aid of recorders they had been able to record a speech. He was sorry to say that he had left these records behind him in London, but he would have very great pleasure in showing them to Prof. Blakesley. That mode—shown on Diagram 4—was practically the only way of connecting up telephones to work. In that case they utilised the self-induction in air. Mr. Gavey had described how they connected up any number of telephones in bridge or shunt, so that intermediate instruments did not affect the circuit at all, but were assistant rather than resistant. Mr. Head asked a question as to the possible future of telephonic enterprise in this country. He was quite right; it was perfectly possible to connect together any two towns, and to place them within decent speech of each other as good as that in London and Paris; but the obstacle was an important one. It was not L electromagnetic inertia, but £ s. d. The difficulty was not that that £ s. d. was not to be found in the coffers of H.M.'s Government, but, as it happened, the telephone interests in this country were in the hands of private companies. It was for them to spend their money in carrying out long-distance circuits between town and town; unless the public, through the House of Commons, could show that they were better served by the Post Office, then, as a member of the Post Office, he (the speaker) would be only too glad to connect Mr. Head's town in the north with his town in the south. He thought he had answered Mr. Wallace's question, and as to Mr. Walker's, there was no doubt that leakage had a beneficial effect. He thought it was Mr. Oliver Heaviside who in one of his papers pointed out that the polarisation effect of leakage must have a beneficial effect, and no doubt it had, as they spoke better in wet weather than in dry. In reply to another question, they did talk between New York and Chicago—a distance, he believed, of 800 miles—but he did not think it was commercial. He thought the greatest distance over which commercial speech was carried on was between New York and Boston, a distance of 300 miles.

Mr. Bennett said he would begin his reply by apologising to General Webber, for it was within his knowledge that General Webber contrived and planned a scheme for telephoning London as far back as 1880. But, unfortunately, his advice on that subject was not taken, and the result was the fortuitous concourse of telephones, now known as the London telephone system. General Webber was under the impression that the young lady operators objected to always listening at the telephones. The reverse was, in fact, the case. By the ordinary system the wants of the subscribers were made known by the dropping of little shutters, and it was necessary for the girls to be perpetually replacing those shutters after they had been dropped, and this was very fatiguing in a long day's work. With the Mann system all shutters were dispensed with. The girls had light telephones attached to their ears, their hands being free, and they had really nothing to do but to sit still, listen, and move their hands; whereas with the American system they had practically to be jumping about all day long. The skill attained by some of these girls was very marvellous. Some of them could actually take messages from two subscribers simultaneously, and understand them both. General Webber thought that it would perhaps be very inconvenient if 50 or 60 calls came at the same moment. So it would, and he did not imagine they could manage 50 or 60; but, as a matter of fact, such a thing never happened. When a subscriber put down his lever to give an order to the operator, should another subscriber have his lever down, the other instantly knew the fact. The formula for giving orders was a very short one; it occupied about one second. The calling subscriber gave his calling number, "400," and added, "on 20"; that occupied but a very short time. Subscribers got into the habit of waiting for each other; and such a thing as 50 or 60 speaking together was quite out of the question. In reply to another questioner, he did not think it was at all possible for the National Telephone Company to alter their existing wires to metallic circuits. As Mr. Preece had told them, not only was it essential to have a metallic circuit, but it was necessary to erect these circuits in a certain way, in order to get the benefit of the double wire. Now, it would be necessary for the present single wires not only to be doubled, but their position on the standards and poles would have to be altered entirely, so the cheaper method would be to take them down altogether and erect new ones. The company's present supporting poles and standards would come in, but the cost of changing single to double wires would, in his opinion, be as much as the construction of a new system would cost. There was another difficulty about it. It would be impossible to change the single wires into double ones at once. The process must go on gradually, and grave difficulties would arise, because it would be necessary to still retain subscribers with single wires to speak to those who had double ones. This could only be done by the insertion of translators, of which a very large number would have to be provided, and the switching arrangements would be very gravely complicated. In 1883 he advised the National Company to effect such a change, but their wires were then few; now the aspect had changed altogether. Mr. Walker thought that the multiplying of trunk wires would be a very costly matter. Of course, they could not put down new junction wires without spending money; but then, it must be recollected, the necessity for these junction wires would not arise until the number of subscribers had increased. Every subscriber would, of course, pay an annual rental, and that annual rental would go to find the necessary dividend on the cost of new junction wires. He could say this with the greatest confidence, because he had had practical experience of the matter. Mr. Gavey had pointed out how it was possible to combine electromagnets with telephonic circuits without spoiling the speaking. He did not say it was not possible to do that. What he said was, it was not done. The American system was followed in this country almost blindly without any alteration, and a part of that system was the introduction of electromagnets on the wires at the switchroom. Every electromagnet took away from the efficiency of speaking, so that with the present system, if several switchrooms had to be spoken through, or several towns, the result would be that the efficiency of speaking would be perhaps altogether destroyed. He had known that expensive trunk lines between important towns 50 or 60 miles apart, costing thousands of pounds, had lain inoperative for months, simply because the American system of retaining magnets in connection with trunk lines was adhered to.

The Aluminium Company.—The palmy days of aluminium are apparently gone, if we may judge from the statements of the chairman of this Company at the annual meeting on Wednesday. When the Company was formed, he said, the price of aluminium was from 60s. to 70s. per pound, but the price had since fallen to from 6s. to 8s. a pound—a price lower than the estimated cost of production. At that price, even with their improved processes, the could not make it at a profit, and he doubted if anybody was makin a profit out of it. The only hope, therefore, for them was in t sodium branch of their business. In that they had a monopol They were now engaged in protecting the new uses of sodium, that even if that monopoly were challenged, they had still som thing to fall back upon in the hold which they might be able have in these new uses. Their financial position was weak, but did not despair of overcoming all difficulties.

CAUSES OF VARIATION OF CLARK STANDARD CELLS.

The following table was inadvertently omitted from Mr. Swinburne's paper on this subject, given in our last issue. The table was referred to on p. 215, col. 1.

* Shaken up with zinc carbonate. † Not altered by shaking up.

PROVISIONAL PATENTS, 1891.

AUGUST 24.

14238. **An improved method of insulating and laying electric light conductors underground.** John Farquharson, Woodland Cottage, High-street, Acton.

14266. **Improvements in appliances for the administration of electricity to horses for curative purposes.** Moses Humm and Arthur Egbert Humm, Leslie House, Westbourne-road, Forest Hill.

14273. **Transmitting signals by means of an electric current, known as "Shadowgraph."** George William Hart, 35, Stodman-road, Newark-on-Trent.

14295. **Apparatus for protecting electric installations for telegraphic, telephonic, and lighting purposes from the effects of lightning or discharges of atmospheric electricity.** George William Spittle, 28, Southampton-buildings, London. (Complete specification.)

AUGUST 25.

14322. **Improvements in portable electric light holders.** William Wallace Savage, 110, St. James's-street, Brighton. (William Wallace Savage, Canada.) (Complete specification.)

14355. **Improvements in telephones.** Cæsar Vogt, Temple-chambers, London.

14379. **Improvements in methods and apparatus for giving increased life and efficiency to arc light carbons.** Nathan Morrison Garland, 45, Southampton-buildings, London. (Complete specification.)

14386. **Improvements in or appertaining to electric motors.** George Cecil Dymond, 6, Lord-street, Liverpool. (Ludwig Gutmann, United States.) (Complete specification.)

14388. **Improvements in and relating to electric motors.** George Cecil Dymond, 6, Lord-street, Liverpool. (Ludwig Gutmann, Germany.) (Complete specification.)

14390. **Improvements in dynamo-electric machines.** Sebastian Ziani de Ferranti, 24, Southampton-buildings, London.

14391. **Improvements in couplings for insulated electrical conductors.** Alfred Shedlock, 24, Southampton-buildings, London.

AUGUST 26.

14397. **Improved electric wire insulating composition.** James Stuart Palmer and Frank Stuart Palmer, 78, Clova-road, Forest Gate, London.

14409. **Improvements in microphonic transmitters.** Gustave Binswanger and Herbert John Coates, 71, Queen Victoria-street, London.

14444. **Improvements in apparatus for the supply of motive power to electric generating stations and other works.** George Forbes, 24, Southampton-buildings, London.

AUGUST 27.

14462. **Improvements in electrical appliances for automatically specifying any predetermined temperature.** Enoch Smith, Bank-chambers, Waterhouse-street, Halifax.

14508. **An improved arc lamp.** John Seaton Warburton, 49, New-road, Grays, Essex.

14509. **Improvements in electrical transmission of power.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, London. (Harry Ward Leonard, United States.)

14517. **Improvements in microphones.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, London. (Siemens and Halske, Germany.)

14518. **An improved construction of primary battery.** Henry Weymersch, 28, Southampton-buildings, London.

14520. **Improvements in electroliers.** James Collins, 47, Lincoln's-inn-fields, London.

14525. **Improvements in electric safety lamps for mines.** Charles Nestor Gauzentès, 22, Southampton-buildings, London.

AUGUST 29.

14585. **The use of asbestos in the working of electrical fittings.** R. H. Newington and E. Priddle, 4, Berry-street, Clerkenwell, London.

14596. **Improvements in telephonic switching apparatus.** Ernest Frank Furtado and Grist and Turner, 55, Gracechurch-street, London.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The receipts for last week amounted to £4,739.

West India and Panama Telegraph Company.—The receipts for August show a decrease of £951 as compared with the corresponding period.

Eastern Telegraph Company.—The receipts for August were £53,398, as against £52,606 for the same period of 1890, an increase of £797.

City and South London Railway.—The traffic receipts for the week ending (and including Sunday) August 30 were £716. 18s., against £728 for the week ending Aug. 22.

Eastern Extension Telegraph Company.—The receipts for August amounted to £41,791, as against £46,526 in the corresponding period, showing a decrease of £4,735.

Western and Brazilian Telegraph Company.—The receipts for the past week, after deducting 17 per cent. payable to the London-Platino Brazilian Company, were £3,215.

Direct Spanish Telegraph Company.—For the half year ended June 30 last the Directors recommend the payment of a dividend at the rate of 10 per cent. on the preference shares, and at the rate of 5 per cent., free of income tax, upon the ordinary.

NOTES.

Sophia.—The contract for electric lighting in Sophia is stated to have been awarded to the firm of Egger and Co.

Budapest. — The Municipality of Budapest have decided to replace 20 per cent. of the present public gas lamps by electric lamps.

Belgrade.—The concession for the electric lighting of the town of Belgrade has been awarded to the firm of Tzikos, Pericles, and Case.

Southend.—The Southend Technical Instruction Committee have appointed Mr. G. J. Burch, B.A., to give a course of instruction on "Electricity."

Bengal Telegraphs.—A new telegraph line is to be built from Rampore Hat to Nya Dumka, which is at present isolated from the network of wires in Bengal.

Cork.—The non-attendance of a quorum at the Cork Corporation meeting on Tuesday caused the question of the application for a provisional order to be put off till to-day.

Egremont.—The Egremont Local Board announce further preliminary correspondence with regard to the proposed electric lighting, but the matter has not yet been decided.

Electric Tanning.—Several works for the electric tanning of hides, says the *Bulletin International*, are at full work in South America, especially in the Argentine Republic.

Bushbury.—A curious item comes from Bushbury, where it appears a meeting of the inhabitants met in the Electric Construction Company's works and decided to light 20 lamps—by gas.

Austrian Electrotechnical Institutes.—Two new electrotechnical institutes have recently been opened in Austria, at Gratz and at Brunn; three others already exist, one at Vienna and two at Prague.

Tower System of Lighting.—The system of placing arc lamps on towers, instead of distributing the lamps along the streets, received its quietus in the taking down of the towers in Detroit, where the system was most advocated.

Electrometallurgy.—A work, entitled "Traité d'Electrometallurgie," by M. H. Ponthière, professor of electrometallurgy and industrial electricity at the University of Louvain, is just published by Gauthier Villars, 55, Quai des Saint-Augustins, Paris, price 10f.

Phosphorescence.—M. Henri Becquerel is studying the phenomena of phosphorescence of minerals under the influence of light and heat, and hopes shortly to be able to announce information which may have an important bearing on the development and storing of radiant light energy in its most intense forms.

Dalton (Lancs.).—At the Lighting Committee of the Dalton Local Board last week, letters were read from Messrs. Nicholson and Jennings, the Manchester Edison-Swan Company, Limited, Messrs. J. D. F. Andrews and Co., and from the United Electric Light Company, respectively, in reference to street lighting by electricity.

French Submarine Cables.—The contracts for the manufacture and laying of two cables from Marseilles to Oran, and Marseilles to Tunis, respectively, have been awarded thus: Oran, to the Société Générale des Telephones, for the sum of 2,471,525f.; and Tunis, to M. [illegible]ammont, Pont-de-Cherni, Isere, for the sum of 2,650,000f.

New Electrical Books.—Messrs. Whittaker and Co. are about to publish a small work entitled "A First Book of Electricity and Magnetism," by W. Perren Maycock. The work is intended for the use of elementary science and art and engineering students and general readers. The same firm have a comprehensive work on the "Telephone" in the press.

Maidstone.—At a meeting of the Maidstone Local Board held on Wednesday, the committee for electric lighting reported that they had a very long conference with a consulting engineer and discussed the application to light certain areas on trial. They recommended that the steps already commenced for obtaining a provisional order be continued.

Electric Mining.—An interesting item from the mining districts of Colorado says that the Virginius Company have contracted with the Edison Electric Company for the erection of a plant for the transmission of 95 h.p. a distance of 3½ miles over the range of mountains 14,000ft. high. Electricity will supersede steam in several of the neighbouring mills very shortly.

Electric Fog Signalling.—Another invention to carry out fog signalling by electricity is being introduced by Mr. Henry Ramsay Taylor, of Lessels and Taylor, 50, George street, Edinburgh. This constitutes a simple means of ringing an electric bell on the engine as long as the signal is at danger. It is actuated by a brush contact or wheel, and the contacts are worked automatically from the signal-box.

Thomson-Houston Meter. — The Société des Compteurs Cauderay et Frager—controlling the patents of the electric meters of these names—have made arrangements with M. Thurnauer, the Paris representative of the Thomson Houston International Electric Company, for the rights of construction and selling of the Thomson meter, which gained the first prize at the recent municipal competition.

Electric Motors for Quick-firing Guns.—Electric motors, it is stated, have recently been applied to Gatling guns, to make these automatic in their action. The results have been surprising. With a current of 80 volts and about 30 amperes, the motor making 150 revolutions, 1,500 shots per minute can be fired, which is far too rapid for ordinary purposes. A regulator is arranged to diminish the rapidity to any desired.

Electric Tabulating Machines.—Mr. Herman Hollerith, the inventor of the electrical tabulating machine, which has been used in making up the returns of the United States census, has shipped to Vienna the final instalment of the order for a dozen of his machines to be used in making up the returns of the Austrian census. It is said that this order came unsolicited, as did also one from Canada for five machines.

Elevated Electrical Railways for Berlin.—The Berlin correspondent of the *Daily Chronicle* says that Messrs. Siemens and Halske, the eminent firm of electrical engineers, have submitted a proposal to the Minister of the Interior and the Berlin Municipality for the construction of elevated electrical railways throughout Berlin and the suburbs. They propose to construct eight different lines, covering some 40 miles, at an estimated cost of 84,000,000 marks.

Errata.—Our attention has been called to a [illegible] awkward misplacement of the diagrams, on page[illegible] 164, in Mr. Kapp's paper on "Electrical Tran[illegible] Power." Fig. 9 should be Fig 11, 10 shoul[illegible] should be 10, 12 should be 13, and 13 sho[illegible] they stand they render the lecture (other[illegible]

clear and easily followed) rather hard to understand. Perhaps our readers will kindly mark their copies in accordance.

Telephone in Kent.—Since the amalgamation of the South of England Telephone Company with the National Telephone Company, the telephone system has made great progress in Kent. A line is being worked down from London, and will cross the Thames at Gravesend, and from thence will be carried from Chatham to Maidstone, whilst a branch line is being constructed to Minster. The work is being carried out under the direction of Mr. Burden, the district manager.

An Electric Garden Pump.—Messrs. Merryweather and Sons, of 63, Long-acre, have a novelty in small pumps, worked by the electric current. As many of our country seats are now supplied with electric lighting machinery, it may be well to consider how the electric energy may be further utilised. Messrs. Merryweather's pump is well suited for garden work, as it is only necessary to fix it by a pond or fountain and attach a suction and delivery pipe, when the little engine will project the water in the usual manner.

The Crystal Palace Electrical Exhibition.—The special committee appointed by the Electrical Section of the London Chamber of Commerce to co-operate with the directors of the Crystal Palace Company in promoting the success of the exhibition, consists of the following gentlemen: Mr. R. E. Crompton, M.I.C.E. (chairman), Major S. Flood Page and Mr. Emile Garcke (vice-chairmen), Mr. J. E. H. Gordon, B.A., M.I.C.E., Mr. G. Binswanger, and Mr. Alexander Siemens, M.I.C.E.

Blackpool.—On the recommendation of the General Purposes Committee of the Blackpool Town Council, it was resolved the Mayor, and Councillors Buckley, Heap, Sergenson, Kingsbury, Leigh, Pearson, and Ward be appointed an Electric Lighting Order Committee, to consider and recommend to the Council what action the Corporation should take under the Blackpool Electric Lighting Order, 1890, with authority to obtain a report on the subject from an electrical engineer to be chosen by the committee.

Automatic Brush-Shifter.—The principle of shifting the brushes to suit the load, used on the Thomson-Houston machine, seems to be likely to be adopted for Brush machines (at any rate, on the other side) if there be anything in signs. Mr. Thos. E. Adams, of the Brush Company, Cleveland, has devised a set of double differential magnets coupled by rods direct to the brushes, whose action tends to shift the brushes of a series arc machine according to the change of load. A sliding weight counteracts the frictional drag of the commutator on the brushes.

Eastbourne.—The borough surveyor of Eastbourne reported at the last Council meeting that he had received a letter from the Eastbourne Electric Light Company stating the charges on the proposed new contracts would be 10d. instead of 1s. per unit, a reduction of 17 per cent. The gas company have granted a further reduction of 7½ per cent. The borough surveyor presented an exhaustive report on the comparative costs of gas, oil, and electricity. It was resolved that in view of the reductions made by the gas company the Council do not make any change in the public lighting.

Waterford.—At a special meeting of the Town Council the following resolution was adopted: "That pursuant to the provisions of the Electric Lighting Acts of 1882 and 1888, we, the Mayor, Aldermen, and Burgesses, hereby resolve to apply to the Board of Trade for a license to supply electricity for public and private lighting purposes, within the borough of Waterford, and an area outside said borough, not exceeding five miles, same to be computed from the General Post Office, and that the Lighting Committee be requested to enquire as to the proper method of obtaining the license, and report to the next meeting of the Council."

Automatic Car Stopper.—An ingenious contrivance for stopping a vehicle when the horse runs away has recently been patented by a German inventor, and is now to be seen in working order at the German Exhibition. It may be possibly applicable to electric trams. By means of a lever working under the feet of the driver, a self-acting spring brake is set in motion, effectually stopping the vehicle. The mechanism is extremely simple, and yet it is guaranteed to work successfully. The harness in the case of a horse carriage can also be made to detach itself instantaneously, and thus free the horse without danger to the driver or the vehicle.

Electricity v. Oil in Burmah.—After many experiments with the different varieties of mineral oil lamps, several millowners in Rangoon have, according to *Indian Engineering*, ultimately introduced electric lighting apparatus on their premises. Messrs. Bulloch Bros. and Messrs. Mohr Bros. have recently fitted installations at their mills at Kemmendine and Poozoundong respectively, and the Burmah Oil Company have just completed fitting up their yards with the electric light. A comparative statement of the two systems—electric and oil lamps—although showing a larger first cost for electric lighting plant, shows that it is cheaper after a time, and possessing numerous and other advantages over oil lamps.

Edison's Latest.—Edison is busy writing a romance of the twentieth century, showing forth the great part that electricity is to play in the coming years. The story, it is stated, is being written in conjunction with Mr. G. P. Lathrop, a well-known writer in America, and husband of one of Nathaniel Hawthorne's daughters. Edison will write the electricity and Lathrop the necessary love story. The motto for the future generation will evidently be, "'Tis love, 'tis love (and electricity) that makes the world go round." The idea is certainly capable of considerable expansion. Bellamy tried it in his famous didactic story, not altogether, perhaps, with the utmost success attainable to an expert. Electricity certainly seems to promise to take possession of the next century, and in the application of inventions to romance Edison ought to be *facile princeps.*

Torquay.—At the meeting of the Torquay Local Board on Friday last, Mr. Briscoe Hooper, their legal adviser, pointed out that the Board were in possession of a provisional order, under which they had powers to light the town by electricity, the estimated cost of the installation being £10,000. There was an Electric Light Committee in existence, and one of the first matters they would have to consider was whether they would advise the Board to carry out the order. If so, there was thus £10,000 to be obtained. He reported this in order that the town might know that the Board had these powers, which the Act gave them two years to carry out. Mr. Harrison said he intended to propose that the Bath Saloons should be lighted at once by electricity. They could do this almost without any cost, and it would be a good experiment. The matter was referred to the committee.

Bath Electric Light Company.—A statutory meeting of this company was held on Saturday. The chairman explained that originally there were only five directors, but the board had been strengthened by three London electricians—one gentleman from the Brush Company, one from the Callender Company, and one from the firm of Messrs. Laing, Wharton, and Down, all of whom

were large shareholders. Of the 3,500 shares offered, 3,241 had been subscribed. Mr. Titley stated that with the present plant they could supply three or four times the amount of electricity. General Jervois said the directors had been giving their attention to the reduction of cost. They hoped to induce people outside the present area of supply to have the light brought into their houses from motors which could be set up in the outhouses. The capital is practically fully subscribed. The meeting closed with a vote of thanks to the chairman.

Whitehaven.—The Whitehaven Town and Harbour Trust are ready to discuss and adopt electricity, as their contract with the gas company expires this month. The Trustees have obtained a provisional order to light their district by electricity, and it is open to them to contract or to light for themselves as they may think fit. The water power at Ennerdale was suggested but thought too small, and the two engines at the sewage works were also spoken of. The chairman proposed that application be made to ascertain the most suitable way to light the town and harbour for 12 months or longer. The motion was carried. The proposals are to be sent to the secretary, who will lay them before the Harbour Committee and the Streets Committee. Other water power than Ennerdale, with greater force, might be obtained; the whole question being one for the careful consideration of the Trustees.

Electric Lighting Company for Leeds.—Recently the Leeds County Council determined to let the electric lighting of the borough to the Yorkshire House-to-House Electricity Company, Limited. Up to the present no move has been made by the company. This is due to many Leeds gentlemen being away on their holidays, and it is impossible at this time to form a local company. At the end of the month, however, steps will be taken to float a company composed of Leeds gentlemen. If this is not practicable, people in other parts of England will be allowed to take shares. When this is arranged, the work will be commenced. Hollow iron tubes are being erected on the Roundhay road, some 30 yards apart, to carry the overhead wires for the electric tramway. Other wires are laid in the ground between the rails. The depôt, near Beckett-street, is rapidly progressing. It is suggested that a large new Board school in Roundhay-road, which is approaching completion, should be lighted by electricity.

Accident in a Paris Central Station.—A tragic accident is thus related by the *Daily News* Paris correspondent: "While the audience were sitting at a performance at the Opera Comique, in Paris, the other night, all the lights went out, and the same thing occurred at the same moment at the neighbouring Châtelet Theatre. Naturally a good deal of surprise and some little alarm were felt, but the darkness was only temporary. At the end of about 20 minutes the little horseshoe lights began to glow again, and the performances at the two houses were proceeded with as though nothing had happened. Meanwhile the police were removing to the Morgue the remains of a poor fellow, the engineer at the establishment from which the electric current is supplied to the two houses. The audience did not learn until after their night's amusement was over that he had been accidentally killed, and that it was his mangled body in the machinery which, interrupting the current, had caused the lights to go out in so unexpected a fashion."

Southend Pier.—The following information with reference to the Southend Pier electric railway, which has been kindly furnished by Mr. Thos. Baines, engineer-in-charge for Messrs. Crompton and Co., Limited, will doubtless prove interesting to electrical engineers and municipal authorities, as it speaks well for the popularity of the electric railway. The tram line since its start has done exceedingly well, and no trouble has been experienced with the line or cars in any way. During the month of July the passengers numbered 57,621, which at 2d. per head comes to £480; this is besides luggage. During the month of August the number of passengers was 86,040, or £717. These results from a small local line up and down a pier are encouraging. It will be remembered that this tram was fitted up electrically last season by Messrs. Crompton and Co., under the supervision of their London manager, Mr. W. A. Chamen. The Crompton dynamo is driven by a Davey-Paxman engine, and the continued good working of the line testifies to the care and excellence of the workmanship.

Electrical Transmission.—In a very carefully thought-out paper, dealing with the minimum cost of plant and maintenance in power transmission, in the N.Y. *Electrical Engineer*, Mr. H. Ward Leonard makes some severe attacks on present formulæ, notably by F. J. Sprague and on Sir Wm. Thomson's famous "interest and cost of copper" law. This law, which Sir Wm. Thomson first enunciated in a paper on "The Economy of Metal Conductors of Electricity," before the British Association in 1881, was given as follows: "The most economical area of conductor will be that for which the annual interest on capital equals the annual cost of energy wasted." This law has been widely accepted, says Mr. Leonard, but on close and practical investigation proves entirely incorrect as applied to maximum economy of an installation, for the surprising reason that no account whatever is taken of the fact that the cost of the engine and dynamo per horse-power transmitted will vary as the loss in the line varies. Consequently the correct minimum and that obtained from Thomson's law are often widely different.

Dundee.—The monthly meeting of the Gas Commission of the Dundee Corporation was held on Wednesday, Sept. 2, Lord Provost Mathewson presiding, when the committee appointed to examine the various systems of electric lighting in other towns similar to Dundee submitted its report. It stated that the committee had visited Bradford, Deptford, Chelsea, and St. Pancras, and that if the Gas Commissioners resolved to supply the light they should adopt the low-pressure continuous-current system, with a station as near the centre to their compulsory area as possible. As regarded the cost it was difficult to get reliable information, but that the cost to the consumer would be considerably over that of gas might be reasonably counted on. In view of the great progress which had been made within the last few years, not only in regard to cost of production, but in many improvements for economical distribution, the committee were hopeful that in a short time an installation in Dundee, if properly gone about, might become at least self-supporting. The commissioners agreed to hold a special meeting to [illegible] subject.

Burt[illegible] ting of the Burton Town Counc[illegible] ders had been received for light[illegible] but the selection had been defe[illegible] the examination of the tem[illegible] for the electric light[illegible] a great amount of [illegible] ere therefore pre-[illegible] that meeting. [illegible] deal with the [illegible] ugg enquired as [illegible] efore electricity [illegible] rman Lowe [illegible] n that he [illegible] own

before the winter of 1892. Up to the present the enquiries for the light had been very few indeed. The Council might rest assured that they would be well within the statutory time, and, if there appeared to be any need for it, they would gladly press forward its introduction. Councillor Rugg thought they were trying to "put off the evil day," and said that several tradesmen were negotiating for their own installations.

Canterbury.—A proposal was before the Canterbury Town Council last week "That the offer of the Brush Electrical Engineering Company to take over the Canterbury Electric Lighting Order, on the terms of their letter, be accepted." The terms were that the company were prepared to undertake the formation of a local company to take over the provisional order which the Corporation had obtained, and to refund to the Corporation the cost of the order, which was understood to be about £200, as soon as the necessary capital had been raised. As an earnest they would deposit 10 per cent. of the cost of the order at once, to be forfeited if the company be not formed, and the total consideration for the order paid within three months from the date of acceptance of the proposal by the Corporation. Alderman Mount explained the proposal, and moved its adoption. Mr. Dean opposed it, and proposed it be not accepted. The town clerk suggested that a committee be appointed to confer with the Brush Company as to terms, and report to the Council. Alderman Mount agreed to this course on the understanding that immediate steps were to be taken, and a committee was accordingly appointed.

Harwich.—A special meeting of the Harwich Town Council was held last week to confirm a resolution passed at the last Council meeting, instructing the town clerk to make an application to the Board of Trade for a license to supply electricity under the Electric Lighting Act, for all public and private purposes within the area of the borough of Harwich. The town clerk, in answer to a question, said the cost of the order would be about £150. Mr. Rose said the Council could specify terms if they obtained a provisional order. They could then ask for tenders to light the town, and retain the option of supplying private persons, the limit of time being 42 years. After obtaining the order there would be no difficulty in getting a company to supply public and private consumers, and he believed that if they adopted the policy of lighting the town by electricity they would have no cause to regret it. Mr. Norman seconded the proposition of Mr. Rose. Mr. Hill moved as an amendment that the proposition be deferred for three months. He thought the plant would cost £7,000 and the maintenance £15 a week. Mr. Everard pointed out that Mr. Hill's amendment meant delaying the matter another 12 months. Mr. Rose said that Mr. Hill seemed to be the only objector. If this proposition were carried and an order obtained, the Council would not be bound to put down Messrs. Crompton's plant, but they would get tenders from other firms. The proposal to obtain an order was carried by a large majority.

Heilmann's Combination Engine.—Our readers will remember that some months ago we gave the outline of a proposal of M. Heilmann, late chief engineer to the Société Alsacienne des Constructions Mécaniques, for the introduction of a new principle in railway practice. It is well known to engineers that the difficulties in getting higher speeds on railways lie chiefly, if not entirely, first, in the difficulty in getting rid of the steam from the quick-moving parts, and secondly, especially on ascending grades, of the need of greater adhesion between engine and metals. Both of these M. Heilmann proposes to obviate at one stroke, by having his engine, a triple-expansion comparatively slow-speed engine, coupled direct to a dynamo, the dynamo to supply sufficiently high-speed motors attached to the axles of every carriage, thus driving each carriage separately. The engine proposed is of 600 h.p., the dynamos and motors of the Rechniewski type. A speed of 50 miles an hour on gradients of 1 in 200 is looked for, and a speed of 70 to 80 miles an hour on the level. M. Heilmann has recently formed a syndicate with a capital of 300,000f. to work out the invention, and it is stated that the authorities of the French railways have accorded permission for experiments to be tried upon their lines. The profits of the syndicate, when made, are to be divided as follows: 10 per cent. to the directors, 45 per cent. to M. Heilmann, and 45 per cent. to the shareholders.

Prizes Offered.—The Société Industrielle of Amiens has offered for the season 1891-2 a number of prizes, consisting of money, and gold and silver medals. These are for answers to questions, amongst which several are with reference to electrical or kindred subjects. If a subject is not completely solved a portion of the prize may be awarded. 1. A gold medal for a brake dynamometer capable of replacing the Prony brake, with more convenient apparatus than the latter. 2. A gold medal for a simple and cheap dynamometer capable of measuring the work absorbed by a tool or machine driven by belt or gearing. 5. A gold medal for a water purifier for steam boilers—simple, cheap, taking little space, and requiring little supervision. 6. A gold medal for the best electric light installation working in an industrial establishment, and costing less than gas, taking works of 300 to 500 burners, making its own gas. 23. A gold medal for a chemical application of electricity in the district. 24. A gold medal for important improvement in the bleaching of wool or silk. 25. A gold medal for the best treatise on the bleaching of hemp and jute, comprising a theoretical study and the examination of the various methods employed in practice. Further, a gold medal of 200f. value will be awarded to all papers that merit this prize—in arts or mechanics, in spinning, in natural history, physics, chemistry, or agriculture; and in commerce and political economy. Manuscripts must be sent, prepaid, to the President, de la Société Industrielle, rue de Noyon 29, Amiens, by the 30th April, 1892.

Queenstown.—At the monthly meeting of the Queenstown Town Commissioners on Monday, Mr. Doran proposed the motion that advertisements be issueed inviting tenders, to be under £300 a year, for the electric lighting of the town for five years from June 30th, 1892, the candle-power not to be under 20,000. He said that the town of Carlow was 17 acres greater in area than Queenstown, and the electric light there was eleven times more powerful than the present lighting of Queenstown, and the cost was only £170, whereas in Queenstown they were paying £474. In Carlow the electric light cost the ratepayers 2d. in the pound, whereas Queenstown was at present paying 6d. in the pound. He had fixed a limit at £300, and if the tender amounted to the fixture it would save the town £144, which would be a saving of 3d. in the pound. Mr. Farrell moved that the matter be adjourned for two months, and that the clerk be instructed to write to the town clerks of Carlow and other towns lighted by electricity to get particulars of the cost of lighting, and its working. Mr. Fitzgerald was not in favour of the Commissioners pledging the rates of the town to the extent of £300. If any company liked to come and make the experiment he would be the last to oppose it. Mr. Doran said that on account of the statement made by Major Curry at a previous meeting that the electric light in Carlow had been unsatisfactory, he had written to the

town clerk of Carlow, and he had replied that the arc lamps at present there had been most successful, but the incandescent lamps had not yet been put up. The amendment was carried by four votes to two, and the town clerk will therefore require particulars of various systems.

Wertz Arc Lamp.—Abolish the commutator of your dynamo, and abolish the mechanism in your arc lamp, and you will have an ideal system of public lighting. Some attempts, more or less successful, have been made towards the abolition of commutators, and alternating dynamos are practical without commutators. The other requirement—an arc lamp without mechanism—if not nearer solution, has at all events been tried and tested. M. Xavier Wertz, of New York, is credited with the solution of this problem, and has produced a combination arc and incandescent lamp which may develop into a successful article. The carbons are placed in an exhausted glass globe, and burn so slowly that no feeding is required, the lamp simply being entirely replaced when burnt out. The construction of the Wertz lamp is as follows: A short, thick, hollow carbon is taken, connected to a conductor, and inserted in a globe. The second carbon passes inside the first, having a solid core and round head, which rests upon the cylindrical carbon. The space between is filled with an insulating layer of asbestos, which prevents any current passing except at the upper surface of the cylindrical carbon, where the two carbons touch. At this point of contact an arc is formed of sufficient size to produce a light of considerable power. The lamp is intended for high-tension series working, and may be fitted with a cut-out and used on ordinary arc lamp circuits. It is possible that we have here the 200-c.p. simple arc lamp that has been sought for. No details are given of its luminous efficiency as regards an ordinary arc lamp. The saving of first cost and attendance, however, might well pay for increased cost of current in many circumstances.

Electric Ventilators for Steamships.—The Commission of Plant and Machinery for the French Minister of Marine has just contracted for the supply from the Société L'Eclairage Electrique of seven electric ventilators on board the steamship "Le Magenta." The ventilators will be fixed under the ironclad bridge, and the whole will be covered in with an outlet communicating with the system of distribution. The disposition of the ventilating plant was required to be easily maintained and taken apart, and each piece is to be as light a weight as possible. The fans are mounted direct on the shaft of the electric motor. Special precautions have been taken to prevent the oil from coming in contact with the insulated wires, and oil ducts are arranged for the escape of used oil. As these ventilators will be required to run continuously for long periods, every arrangement has been made to prevent the various parts of the motor from overheating. The interior coils of the motor have been so arranged as to give at will two different speeds by the simple movement of a commutator, the normal speed being 1,200 revolutions. The lower speed is 600 to 900 revolutions, the alteration taking place without addition to the exterior resistance to the motor circuit. The following are the general details: Pressure, 70 volts; current, 18 to 20 amperes; revolutions, 1,200; pressure of air in height of column of water, 2 cm.; diameter of disc, ·64 metre ($22\frac{1}{2}$in.); total weight, 616lb. In the Government test the ventilator was placed in a wooden box, whose dimensions reproduced the space left free in the "Magenta." The opening was reduced to an outlet of 6 decimetres square. The ventilator, with 70 volts at the terminals, and a current of not over 20 amperes, was found to maintain a pressure of 2 cm. of water, corresponding to an output of 4,000 cubic metres an h[illegible] These tests were carried out to the entire satisfaction of the commission.

Electricity in Mining.—At the annual meeting of the National Association of Colliery Managers at Newcastle on Friday, Mr. Henry Palmer, of East Howle Colliery, Ferryhill, the president, alluded in his address to one subject which is growing daily in interest and importance, and one which will soon force itself upon his notice—electricity. "It is true," said Mr. Palmer, "that some of us have ventured to employ this new and mysterious agent in a few cases, and I am proud to think that our association counts as a distinguished member one who has been a veritable pioneer in the application of electricity to mining, and more particularly in the way of underground pumping. To Mr. Frank Brain I owe a deep debt of gratitude for assistance freely given. There are at the present time several small electrical pumping plants at work in the county of Durham, and at East Howle we are pumping 1,000 gallons per minute in that manner. It is also being introduced in the North for hauling and other purposes. I advise colliery managers to begin to accustom themselves to the new agent, and to make themselves familiar with the rules relating to the measurement of an electric current. The necessary solution of many unsolved problems in mining lies with you, gentlemen, and I have every confidence that whether absolute scientific and practical rules can be established or not to satisfy the ever-varying conditions of mining, the consideration of such subjects may be safely left with you, and I am content that the results will in the future, as in the past, be received by the mining world as steps towards the higher social, scientific, and intellectual position of colliery managers, and a simplification of the manifold duties they are called upon to perform."

Closed-Conduit System.—An interesting exhibit at the Frankfort Exhibition is a novel and simple closed-conduit system of electric traction by Messrs. Schuckert and Co., of Nürnberg. The closed conduit systems hitherto tested in practice in this country comprise two kinds—that advocated by Mr. Lineff, in which a continuous conductor laid underground is drawn up into communication with the conductor sections, one after the other as the car proceeds, by the attraction of a magnet placed on the car; the other, advocated by Mr. J. Gordon, charges the conductor sections by a return insulated circuit actuated by magnets placed not in the car, but in a box under the pavement. Schuckert's system is of the first order, based upon the Lineff principle; but instead of using a continuous thin strip of iron which is raised magnetically to make contact, Messrs. Schuckert employ iron filings, in the following simple expedient. The conductor sections are laid along in the roadway upon solid wood planks, bedded in the ground, under which is the main strip conductor. Each wooden plank is pierced downwards at intervals along its length by taper holes of $1\frac{1}{2}$in. to 2in. diameter, which have the smaller diameter at the top. Before laying the iron conductor rails over the planks, these h[illegible] each partly filled with a handful of iron filin[illegible] down upon the main conductor. As th[illegible] its magnet energises the roadway beneat[illegible] filings [illegible] in a heap and make conta[illegible] falling again as the car pass[illegible] prevents their continued c[illegible] the number of holes an[illegible] obviate all difficulty with[illegible] The car was not work[illegible] visiting the Frankfort [illegible] state from experience [illegible] It was, however, stat[illegible]

PENDANT FITTINGS FOR SHIP LIGHTING.

The enclosed sketches show an improved form of pendant, designed by Mr. Malcolm Sutherland, electrical engineer to Messrs. Wm. Denny and Bros., Dumbarton. Fig. 1 shows the complete fitting. B B is the back block made of teak boiled in paraffin, to which the brass junction-box, J B, is attached. The wires are led in through water-tight stuffing-boxes, and attached to the screwed junction, J. The stalk of the lamp, S, is then screwed into its place,

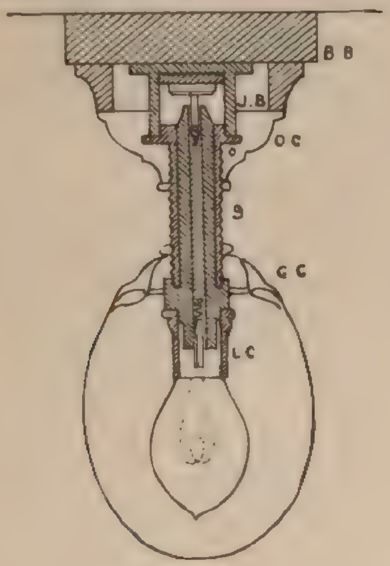

FIG. 1.

making contact with the junction J. Then the ornamental cover, O C, is screwed hard up against the wood, jamming the stalk and preventing it from getting loose. To prevent the cover from slacking back, two screws are driven through the flange into the wood. G C is the usual Edison-Swan globe carrier. Fig. 2 shows the upper and lower ends of the stalk, S. J B C is the junction-box cover which is permanently attached to the stalk. C is a rod of

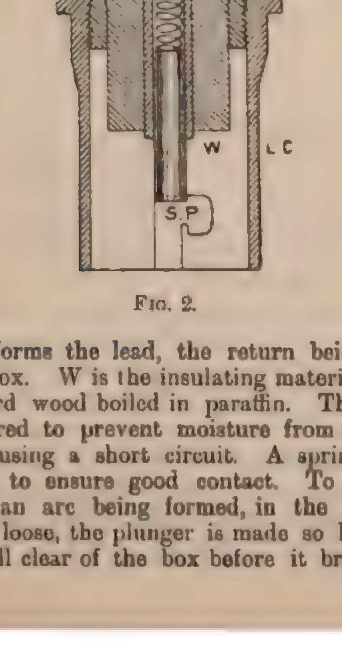

FIG. 2.

brass, which forms the lead, the return being the stalk and junction-box. W is the insulating material, being also formed of hard wood boiled in paraffin. The upper end of this is tapered to prevent moisture from lying across the top and causing a short circuit. A spring plunger is attached here to ensure good contact. To prevent the possibility of an arc being formed, in the event of the fitting getting loose, the plunger is made so long that the fitting must fall clear of the box before it breaks contact. In the old form a central contact lamp was screwed into a nipple on the lower end of the stalk. In the new form the wood is carried right down into the lamp carrier, L C, and another spring plunger is attached. By this arrangement we have only two joints instead of three. A small tapered shoulder is turned on the wood, which, being jammed between the end of the stalk and the nipple, N, prevents it from changing its position. This form of pendant is now being used by Messrs. Denny for ship lighting.

PRIORITY IN ALTERNATING-CURRENT MOTORS.

The question of priority in the discovery of the alternating-current motor would seem to need definite settlement, both on account of historical accuracy and the avoidance of acrimonious discussion. It has been usual, in Europe, to ascribe to Prof. Ferraris the priority in the demonstration of the possibility of rotary motors being obtained from alternating currents, and in a recent *résumé* of the subject M. Hospitalier so accorded the credit. The dispute, so far as fundamental principles are concerned, is limited to Prof. Ferraris and Mr. Nikola Tesla ; and the New York *Electrical Engineer* this week vigorously asserts the priority for America in the person of Mr. Tesla.

The following are the words of our contemporary: "Prof. Ferraris has been credited with the discovery now in controversy on the strength of his admirable paper, read before an Italian scientific society, in March, 1888, and published in Italian shortly afterwards. But five months before this, in October, 1887, Mr. Tesla had already filed applications for patents embodying the discovery, and several months before that time had so far perfected his invention that a company had been formed to exploit it. Many prominent persons, including several electricians, then saw the Tesla motors at work ; and during the winter of 1887-8 one of the best-known scientific men in this country (America) examined and reported favourably upon them. Some time in April, one of the present editors of the New York *Electrical Engineer*, knowing of this new work, saw the motors which had then been running for some time in a temporary laboratory, and induced Mr. Tesla to bring his discovery before the May annual meeting of the American Institute of Electrical Engineers. The motors were actually shown in New York before a large gathering.

"On May 1, 1888—the same year—patents were issued to Mr. Tesla in America as the result of his application in October, and were then accessible at once in every European country. But the work of Prof. Ferraris was not brought to light in English-speaking countries (and others, too, for that matter) until it was given prominence by the publication of it in *Industries*, May 18, 1888. That interesting article was freely copied, as it well deserved, and its publication in this wise created the false idea that Prof. Ferraris's striking work was simultaneous with that of Mr. Tesla, or even prior. But the description of the Tesla invention must have evidently been made public on the patent, in England and other countries, before the date of the *Industries* article, and besides the fact of the issue of the patents there is the fact that a contemporary, the New York *Electrical Review*, had given a short illustrated description of the Tesla motors on May 12.

"More than this, in his essay of March, 1888, Prof. Ferraris expressly denied the practicability of motors that Mr. Tesla already had in successful operation ! He hinted at the possibility of using a proper generator for such motors, but no further did he go. Mr. Tesla had already taken coal out of the mine before Prof. Ferraris had made his geological survey of the region. With this admission from Prof. Ferraris, it was not very likely that practical men would recognise the great value of the new principle.

"On examination of Mr. Tesla's now familiar work, we find that he, on the contrary, had not stopped short at a mere rotating field, but dealt broadly with the shifting of the resultant attraction of the magnets ; that he had evolved the multiphase system ; that he had shown the broad idea of motors employing currents of differing phase in the armature with direct currents in the field ; that he had shown both synchronising and torque motors ;

e had shown how machines of ordinary construction be adapted to his system, and had with specific pur- advanced boldly into new territory, of which there ot the slightest hint or suggestion in the work of Ferraris. In other words, Mr. Tesla not only went to ttom of the fundamental principles, but tried them ry detail that inventive ingenuity could hit upon. If not so, it is time to have the contrary state of affairs d before Mr. Tesla loses the credit that such work give him."

THE LIGHTING OF RAILWAY TRAINS ELECTRICALLY.*

BY J. A. TIMMIS.

not advisable here to enter on any lengthened dissertation he relative merits of oil or gas or electricity as a means of g, as such, to be complete, would involve many intricate sues connected with the expense of first cost, and the ant and complex ones of maintenance and labour.

e can, however, be no doubt, and we may take it as gene- dmitted, that the light from oil lamps is not sufficient to the wants of the travelling public.

light given by the most approved system of gas lighting is btedly far superior to that supplied by oil lamps, but it is al to that given by high candle-power incandescent electric

test which must be applied to any system of train lighting ght equal to daylight on a fairly clear day—in other words, sufficient to enable anyone to read at night with the same nd comfort that he can when travelling in broad daylight. s self-evident on reflecting that at most stations papers are nd that the sale of papers, periodicals, and books on railways own into an enormous trade.

experience after hard and anxious work, spreading over ears, gained from the lighting of some 300 carriages, most n long bogie cars, is, that while it is perfectly easy to light rriage or any train successfully, and to give absolute and nt satisfaction to the railway authorities and also to the ing public, it is a matter (now that it is attained) of impera- cessity to give a system which is not extravagant in first nd is (and this is of far greater importance) economical in and renewals—*i.e.*, in working and maintenance.

may lay it down as a law to begin with, that, in order to the greatest efficiency and economy, a whole railway must be lighted and not merely a portion of it.

as it is most improbable that any large railway company light the whole of its stock at once, it is an evident age to have a system which enables the stock to be fitted lly.

ng stated these primary conditions, we will consider a r of other conditions which we find are imperative in detail. ach and every carriage must carry its own store or reservoir ricity, because it may be attached to any train throughout tem, and then may be taken off or slipped from the train it lling with and attached to another (or the same) train at portant station, and while detached the carriage, if , must remain so. In addition to this—(*a*) The weight of ctric battery in each vehicle must be small, on account of and expense. (*b*) The batteries must not be liable to be d when the carriages are in regular work, neither must any e be detained at any point to have its battery charged. carriage must be free to be used in traffic always.

order to give such an amount of light (as mentioned above) be equal to daylight—(*a*) The lamps used should be 16 c.p. voltage used to drive them should be as high as practi- because the consumption of electricity (a most important is materially reduced. We find that 50 volts is the safest The carbons of lamps of over 50 volts will not stand railway ing. (*c*) The reflectors should have a convex and diffusive

he light must be under the control of the guard.

e are three methods by which electricity may be generated lighting of railway carriages.

By a dynamo driven from an axle of the train, and this is mes necessary, but never advisable. A dynamo must be from the axle in the case of a Waggon-Lits train, because mpany does not own or work the locomotives, neither do ssess any rights in the railway stations. In addition to onditions, the speeds of their trains are uniform and the es between stoppages are very great, so that the conditions only special but as favourable for axle driving as they can Russia, also, the very long runs and the low and uniform f trains, added to the difficulty of fixing a dynamo and on the locomotive, make it sometimes advisable to use axle dynamos. But under ordinary circumstances, axle-driven s are most objectionable, because—(1) The field magnets be larger in proportion in order to deal with the increase d between that at which the dynamo cuts in to charge the s and the maximum speed of the train. This is sometimes 3. (2) The gearing is very soon worn and destroyed. (3) al set of skilled workmen have to be employed in order to em in order. (4) Practically, every van would have to be fitted with a dynamo, and also with a large battery. The expense entailed being beyond all reason, as, if there is a dynamo on the train, there should not be any electric battery to light the main lamps.

2nd. Another method is to drive a dynamo on the train by a special engine, using locomotive steam (in special cases we have used a special boiler in a very large van; but the circumstances were exceptional, and the objections to its general use are so obvious that it is not necessary to mention it further).

3rd. The third method for the generation of electricity is to employ a plant at certain important stations to light the stations and yards, and at the same time to charge the batteries used in lighting the trains.

These two latter systems each have their advantages.

With a dynamo and special engine on the locomotive—(1) Which are self-contained, and which only vary less than 1 per cent. in speed, with a variation of up to 50 per cent. in steam pressure—*i.e.*, which are constant in speed and also in electrical efficiency. (2) Which are not over 3ft. 6in. high by 4ft. by 2ft. (3) Which start automatically when steam is turned on. (4) Which are boxed in from dust and wet, and do not heat. (5) Which do not require lubrication for several days when in constant work. (6) The locomotive driver has very little extra work and no attention to give to this. And we have obtained all these points.

It is clear that the generation of electricity for lighting trains becomes simple and economical, especially when (*a*) the high voltage necessary to run the lamps efficiently and economically can be readily obtained. (*b*) A main battery is not necessary by our system. (*c*) As will be seen hereafter the total weight of batteries on a train of 12 long bogie cars is only about one ton.

On the other hand, if the main lighting is effected by main batteries in the vans, and they are charged at central stations by large plants which also light the stations, the following economies are effected: (*a*) A few large plants serve to generate the electricity required to light all the trains on a railway system, and also to light the stations instead of a large number of small ones. (*b*) A few skilled men only are required. (*c*) The deterioration of large plants is much less than in the case of dynamos on the trains. (*d*) The efficiency and economy of large plants is proportionately greater.

We come now to the point where it is necessary to describe the arrangements which we find most suitable and economical for carrying out the above conditions, and getting over all difficulties.

We fit the carriages with 16-c.p. 50-volt lamps, and we light these lamps either with a special engine and dynamo on the train, or with a battery consisting of 26 accumulator cells placed in the guard's van. These lamps, which we call the main lighting lamps, consume ·6 of an ampere each, whereas a 32-volt lamp consumes over an ampere. This is a very great advantage and economy in the working of railways. The extra number of cells—viz., 26, as against 18—being far more than counterbalanced by the saving of nearly 50 per cent. of electricity (*i.e.*, cost of charging and weight of lead per cell), and the increased amount of light.

But as each carriage has to carry its own storage of electricity for the reasons stated above, and as it is not practicable to put 26 (or even 18) cells in each vehicle, because of (*a*) the weight; (*b*) the first cost and maintenance; (*c*) the difficulty to charge them with a dynamo on the train, and impossible to do so with central charging stations, we have worked out and patented all over the world—even in Germany and the United States our claims have been fully allowed—the following arrangement, our main object being to minimise the weight and cost of electric batteries.

In addition to the main lighting we place small voltage lamps (eight volts we find sufficient) in the carriages, and a small four-cell accumulator battery in each carriage to light them. The leads and couplers and switches will be described presently.

These small lamps may be separate from the main lamps, but we have patented and are regularly using lamps with two filaments in. These lamps are shown in Messrs. Edison and Swan's catalogues and in the drawings herewith. They are so arranged that as soon as a pair of couplers are separated they are automatically lighted in the carriages that are separated from the main circuit, by the small batteries. They are also under the control of the guard.

The small batteries are very light (weighing per carriage less than 1cwt.), they are not costly, and they are kept charged by the engine and dynamo or the main battery in the guard's van as required. Thus every carriage is free to be used in any train, and the only batteries that require special arrangements for charging, if any, are those in the guard's van.

In order to effect the [illegible] of these at central stations, we designed, some three [illegible], special light trucks, with the top flat platform [illegible] ards its height, and sufficiently large to hold tw[illegible] atteries.

One of these [illegible] freshly charged battery at a charging stati[illegible] receive the battery from the van, and the [illegible] place. The contacts are made automatically.

It must be [illegible] only times the auxiliary lamps are used are w[illegible] off a train and perhaps put, for a few min[illegible] a siding [illegible] ed on to another t[illegible] slipp[illegible] and while it is [illegible] me the auxiliary [illegible]

In the [illegible] ain of some [illegible] then [illegible] electric [illegible] train: [illegible] equally [illegible]

---

* Paper read before the British Association.

Having described the main conditions which we find necessary to fulfil, and the general mode of dealing with those conditions, so as to give an economical and efficient system for lighting railway trains, we will describe the drawings and diagrams in order to make the details of working the two last systems clear.

also a local switch, I, in each carriage which governs the lig each individual carriage without interfering with the rest train. The same action takes place if there is a dynamo locomotive instead of a main battery.

The charging of the auxiliary batteries is effected from the battery or from the dynamo on the locomotive as follows

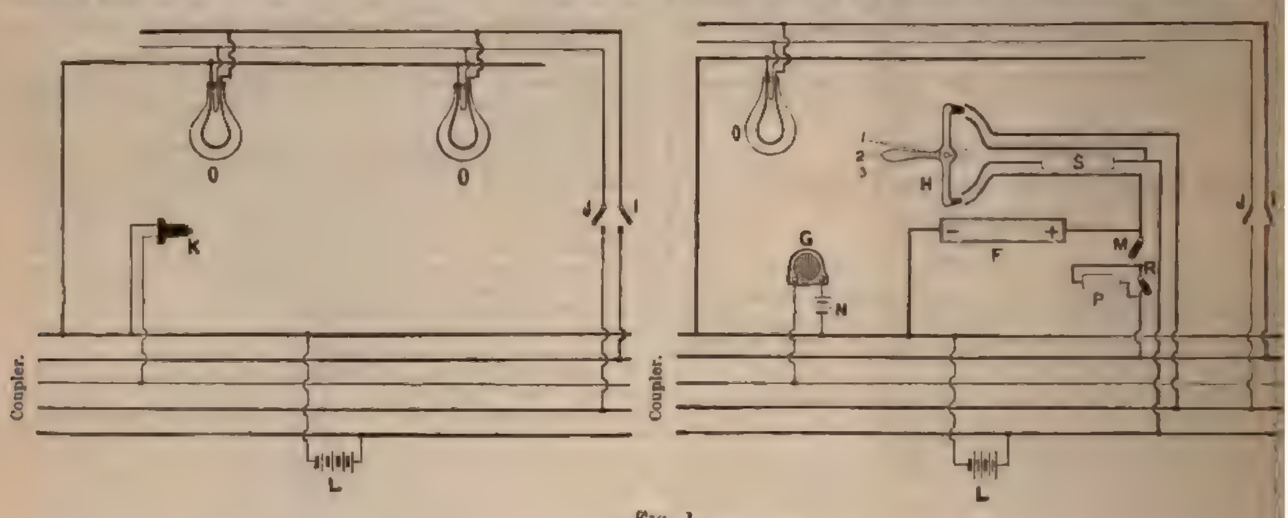

Fig. 1.

There are two diagrams. First, the larger one, explaining the "four-wire" system. The five leads, A, B, C, D, E, run throughout the whole length of the train and are joined up from carriage to carriage by the couplers. A is the main negative. B is the main positive from the large battery, F, or from the dynamo with its

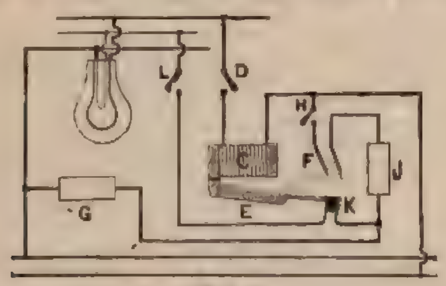

Fig. 2.

special engine. C is the communication positive wire. D is auxiliary lamp main lead, and E is auxiliary battery main lead. It is evident that if D and E are joined, the auxiliary lamps will light up, provided the local switches, J J, are closed. F is the main battery of 52 volts. G, communication bell. H, auxiliary battery three-position switch. J J, auxiliary lamps local switches. I I, main lamps local switches. K, communication push. L L, auxiliary batteries (it is possible to do without the auxiliary battery in van). M, main lighting switch. N, bell battery. O O, main lamps with auxiliary filaments (the auxiliary lamps may be

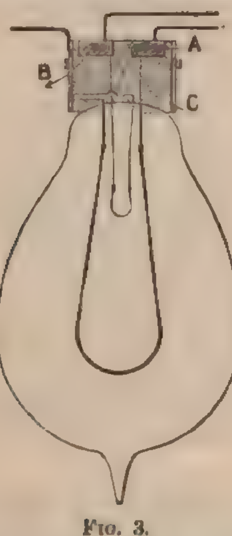

Fig. 3.

separate from the main lamp). Before describing the action of the system, I may say that safety fuses are fitted in every carriage, but these have not been shown in the figure in order not to complicate it.

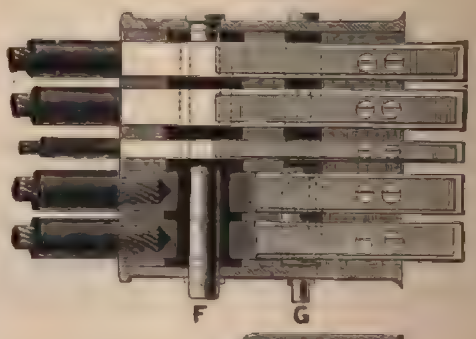
As will be seen from Fig. 1, when the train is coupled up the whole of the main lamps are lit from the battery, F, which is switched on to the circuit by a switch, M (in combination with a switch, R, and resistance, P, to equalise the discharge). There is

switch H is placed in position 3, and the current flows th S to all the small batteries in the train in parallel, the resis S, being adjustable to the number of batteries in the train.

Fig. 4.

H is in position 1, the auxiliary lamps are lit from the aux batteries. This is necessary, for example, in the case of cha the main battery at a station. The small batteries can, of co be charged in series if it be found desirable.

Fig. 6.



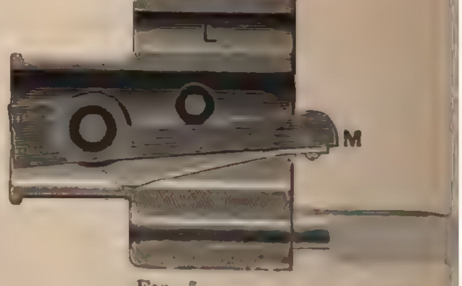


Fig. 5.

The communication system, with its push, K, in each car or compartment, its main lead, C, bell, G, and small battery, self-evident and needs no explanation. It may be worked by main battery if desired.

The action of the automatic coupler strips, D E, is as foll Should the train be parted anywhere, the strips D E, in couplers that are severed, come down to the piece J, Fig. 4, the lead D, Fig. 1, is thus connected to lead E, and the cu

thus flows from the auxiliary batteries to the auxiliary lamps. When the train is once more coupled up, the connection is broken at the piece J, Fig. 4, and the main lighting leads then come into action, and the auxiliary lamps go out.

The smaller diagram, Fig. 2, represents the working of the same systems by the use of two through leads instead of four. This we consider equally efficient and more economical.

The main lighting current from main + B passes round coil C, and, when switch D is closed, lights the large lamps or filaments, and in passing round C, it actuates armature, E, raising it and making contact, F, and holding it there during the whole time main lamps are lit. The auxiliary battery, G, is thus placed in communication with main + by means of the switch H, which, when closed, charges the auxiliary battery through the resistance, J.

When the main lighting circuit is broken in any way, the current in C is also broken, and the armature, F, falls and makes contact, K, and the auxiliary switch, L, being closed the auxiliary lamps light up. When the main lamps are once more lit the auxiliary lamps are automatically put out by the action of E.

In the double-filament lamps, Fig. 3, the large + is connected to piece A, the small + to piece B, while the brass casing, C, forms the common negative to both filaments, and this casing makes contact with the lampholder which is attached to the general negative main.

Fig. 4 shows cross-section of the coupler for the four-wire system; Fig. 5 the longitudinal section; and Fig. 6 the sectional plan. The five strips correspond, and are attached to the five leads, A, B, C, D, E, respectively, shown on main diagram, Fig. 1.

The strips are all pivoted on the pin F, and are all insulated from it and from each other by the insulation shown in black. The pin G carries upon it the insulating piece, H, upon which the three strips A, B, C rest when the couplers are detached, and it also carries the brass piece, J, which is itself insulated from the pin G. The object of the piece, J, is to automatically connect the two strips D and E when the couplers are separated, and thus light up the auxiliary lamps, as shown on diagram of general arrangement. The pin, K, entering the hole, L, of the corresponding coupler, ensures the accurate meeting of the various strips and prevents short-circuiting. As the couplers are pressed together, the curved ends of the strips engage with each other and hold the couplers together. The springs, M, keep the strips in connection with their corresponding strips, or with the piece J when advisable. If the two-wire system is used, only two strips are necessary.

In conclusion, we would remark that we can only claim as absolutely new in principle (as apart from the details of couplers and double-filament lamps and other mechanical matters) the combination of a main lighting circuit with high E.M.F. and efficient economy, together with an auxiliary lighting circuit and lamps with small batteries and economy in weight, cost, and maintenance.

Discussion.

Mr. Killingworth Hedges thought that the subject of train lighting was one of great importance. It was to be regretted that Mr. Timmis's paper did not come on earlier in the day, when more attention could have been given to it. With the main conditions laid down by Mr. Timmis, particularly the one which stated that every carriage ought to carry its own store of electricity, he cordially agreed; in fact, he had advocated the same plan three years ago at the British Association meeting at Manchester. He must say, however, that it had been rather difficult to convince the railway authorities that they must, in order to break up their trains, put a battery in each carriage. It appeared to him that the main circuit and the auxiliary circuit when connected must be a very complicated system, and, indeed, one that would be difficult to arrange unless rolling-stock were joined together. He could not see the good of the auxiliary circuit, because if they lighted with batteries connected up in a carriage, why not put in batteries of small capacity, perhaps, three or four hours' storage, and work them from the dynamo, which in ordinary times when the train is in motion lights the whole installation. The auxiliary limits of lower candle-power would offer grave objections, because people would sooner do without the electric light than have it suddenly lowered. In his (the speaker's) paper at Manchester, he mentioned batteries having zinc and lead electrodes. Since then little had been done with them, but the other day, when seeing Mr. Webb, of the North-Western, he was told that they were acting extremely well, experimentally. If such cells were used they might obviate the difficulty complained of by Mr. Timmis in ordinary secondary batteries. At any rate, he thought it would be quite practicable to put a set of batteries either of zinc and lead or the ordinary batteries in a carriage, and get sufficient capacity to attempt all the lighting during ordinary stoppages at stations. One great objection to heavy batteries was the liability to be broken. When travelling on the Midland the other day, where a good system of electric light was used, he found the electric light was not at work. Upon asking the reason, he found that the train at one of the stations ran into the station buffers with sufficient force to knock the batteries out of the case and break it, and the orders were, that until it was put together again, not to use the dynamo. On the Midland they had tried successfully a very important experiment, and that was one advocated at the British Association by Mr. Preece: it was known as Mr. Barber-Starkey's plan, and consisted of filling up cells with plaster of Paris and making them quite solid, and he was told that it acted admirably. In conclusion, the speaker expressed confidence in the fact that electricity must very soon be the illuminant used for trains, and pointed out disastrous consequences of a collision between trains lighted by gas.

Mr. Bennett referred to a system of lighting used on the North British Railway.

Mr. Smith, in replying for Mr. Timmis, said, in reference to Mr. Hedges's objection to heavy batteries, it was that very reason which impelled Mr. Timmis to put small batteries in each carriage. Mr. Hedges did not quite see that was that system—no dynamo was used. If there was a large battery, then there was no small one. It amounted to this, that if they had a charging station where they lighted the railway station, one used the same plant to charge the big battery in the guard's van. If the big battery was employed to light the main lights, then only little batteries were required to light the auxiliary lights. These could be left in the carriages from one month to another, with only occasional supervision, because they were charged from the big battery. As to the diminution of light it was not so serious as Mr. Hedges supposed. The reduction was from 16 c.p. to 10 c.p., which was quite good enough to read by. This, however, only occurred in stations, and it was supposed that the diminution of light here would not be very noticeable—at least, it would form no serious inconvenience.

ON THE ELECTRIFICATION OF STEEL NEEDLE-POINTS IN AIR.*

BY A. P. CHATTOCK.

(Concluded from page 203.)

Although the silent discharge from a point does not appear to have the power of permanently clearing away surface-resistance, sparks do so readily enough—though under suitable circumstances they will also form it again. In making the measurements on needle B (Table I.), the discharge at the last recorded (+) reading took the form of a spark. $\sqrt{P}$ was here 1·50. On repeating the reading it had risen to 1·95. A third discharge brought it back to 1·62, and after that it continued to oscillate between these two values for some 20 or 30 times with hardly a break in the regularity. Obviously one spark formed a resistance and the next blew it away again. The character of the sparks was quite different, too. The one which formed the resistance was thin and sharply defined, and spread out for a considerable distance over the plate like a splash. The other was much brighter, straight, and without any signs of a defined edge.

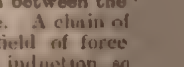
While, however, the above is evidence of the existence of surface-resistance at used points, the fact that the values of f at beginning and end of discharge are practically identical for a clean point for both positive and negative electricity, may be regarded as showing that such resistance is either very small or non-existent on points which have not been used before.

Atomic Charge

§ 6. Assuming, then, provisionally that cohesion in Grotthuss chains is the sole cause of the resistance offered to discharge at a clean point, and that gas atoms are consequently concerned in carrying the electricity when it does so,† there arises the interesting question as to the amount of charge carried by each atom; and one is tempted to see whether the above measurements throw any light on it. Without in any way pretending to settle the point, the following considerations seem to me to render it probable that the electro-chemical equivalent of gas atoms is of the same order of magnitude as that of the same atoms in electrolytes.

The essence of a Grotthuss chain is that it shall consist of molecules capable of being split into two parts, one of which is charged after the split with positive electricity and the other with negative. These charges may exist separately in the molecules to start with, or they may be induced by an electrostatic field—but in either case it is the field which subsequently arranges them in chains; and the breaking down of the chains occurs when the mechanical pull of the field on the charged parts is sufficient to overcome their mutual affinity. This affinity may be due to one of two causes or their combinations. Either it is (a) the electrical attraction of two initial charges, or it is (b) a cohesive attraction without any previously existing charges, or it is (c) both. One of these three it must be, if by cohesive a[illegible] is understood the sum of all non-electrical forces b[illegible] parts of the molecule.

Consider the first (a) of thes[illegible] as hold together by internal charges, t[illegible] in their free state:

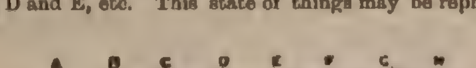


the lines in between the [illegible] static force. A chain of [illegible] put in a field of force [illegible] charges by induction, so [illegible] and B, C and D, etc., [illegible]

* Paper read before [illegible]

† This does not pr[illegible] [illegible]rge after it has [illegible]

B and C, D and E, etc. This state of things may be represented thus:



Put in another way, the strength of the field which will do this is rather greater than that which would induce on each of the two end atoms of the chain half their assumed initial charges, supposing them to be connected by a fine conducting wire. It depends thus on the length of the chain being greater as the chain is shorter.

In the case (*b*), a constant cohesive affinity between the two parts of the molecule, it is necessary to suppose that electricity can pass from one to the other under the influence of induction when they are put in a field of force, in order that after separation they may be oppositely charged. The following figure shows

a chain of such molecules on the point of breaking down, the break occurring when the cohesive forces (~~~~~~) are just overcome by the electrical forces (═══) set up by the field. Here, again, the longer the chain the weaker the field required to break it; and as the cohesive forces are constant, and the electrical forces are dependent, for given molecular arrangement, only on the charges induced in the molecules, it follows that these charges will also be practically constant, no matter what the length of the chain may be.

In both these cases, therefore, for all lengths of chain, the atomic charges at the breaking point are constant; in case (*b*) being rather less than such as would be induced by the field on the end atoms, supposing the latter to be connected by a conductor; and in case (*a*) less than twice that amount (less because the chain is not a continuous conductor). Their values might thus be calculated in terms of f if the geometrical conditions were known. This, however, is not the case under the conditions of actual experiment; but by arranging that the chains shall consist of single molecules only, it is possible to get an idea of the magnitude of the charge in question. Reduce in imagination the discharging point to molecular dimensions; and find, by what is rather violent extrapolation, the corresponding value of f at discharge from the constant in Table II. The Grotthuss chains will have been reduced to single molecules by the reduction of the point, and by supposing them to be spheres the + and − charges induced on their opposite sides may be calculated. These charges will then represent in the case of (*a*) half, and in the case of (*b*) the whole of the atomic charge.

Taking the diameter of a molecule as $\frac{1}{2} \times 10^{-8}$ centimetres, the value of f at the centre of a molecule opposite the point is (from Table II.)

$$f = \frac{16 \cdot 5}{4} \times \left(\frac{1}{4} 10^{-8}\right)^{-0 \cdot 8} = 3 \cdot 1 \times 10^{7} \text{ E.S. units.}$$

which will induce on a conducting sphere of the same dimensions equal and opposite charges of

$$\frac{3}{4}\left(\frac{1}{2} 10^{-8}\right)^{2} f = 6 \times 10^{-10} \text{ E.S. units,}$$

This number is greater than the atomic charge (or than half the atomic charge) because it is calculated from measurements on chains of many molecules, which, as was pointed out above, are not conductors, but only lines of high S.I.C. Now the most probable value of the ionic charge of oxygen is 10^{-11}, which, considering the extent of the extrapolation and the fact that the above number is too great, is in sufficiently strking agreement with it. It is at any rate satisfactory that the experimental number is the larger of the two.

It is interesting to see whether a similar result is to be got from measurements of sparks between plates. Taking Dr. Liebig's numbers above referred to, I find, following Prof. J. J. Thomson, that the formula $f = \frac{a}{l} + 150$ expresses the results for the smallest spark-engths in air fairly well, considering that the numbers for that part of the curve are rather irregular. The values of a lie between 1·9 and 1·4 for the five smallest spark-lengths ($l = 0 \cdot 0066$ to $0 \cdot 0245$ centimetres. Extrapolating for a distance between the plates of $\frac{1}{2} \times 10^{-8}$, the field between them comes to be 4×10^{8}. This would induce a still higher charge (8×10^{-9}) on a spherical molecule; but it must be remembered that these data are much further removed from molecular dimensions than mine.

On the other hand, there is a case accessible of what may perhaps be called discharge between plates, which takes place actually within molecular dimensions: I mean the passage of electricity at the cathode of a voltameter. Here, if a step of potential of, say, one volt be assumed, and if f stand for the corresponding field between the liquid and the metal of the cathode,

$$f \times \frac{1}{2} 10^{-8} = \frac{1}{300}, \text{ or } f = \frac{2}{3} 10^{6} \text{ E.S. units.}$$

This is capable of inducing on a spherical molecule charges of $1 \cdot 5 \times 10^{-11}$ E.S., a number which cannot be distinguished from the ionic charge. Moreover, no reduction is necessary here as the data of calculation are from measurements made direct on single molecules.

Taking, then, these three calculations together, and having regard to the fact that the nearer the conditions of experiment approach molecular arrangement the closer are the results to the value of the ionic charge, I cannot help thinking that they furnish strong grounds for supposing that electrified atoms in gases are associated with the same quantity of electricity as in electrolysis.

As regards the third possibility of molecular cohesion (*c*) mentioned above, that it is due to a combination of (*a*) and (*b*), it is impossible, without knowing the relative values of the two forces at work, to get any idea of the atomic charge from the value of f. All that can be said is that it will be less than the value calculated for atoms held together by electrical attraction only. Even in this case, therefore, there is nothing to negative the presence of ionic charges in gaseous conduction.

Effect of Pressure.

§ 7. If the conclusions arrived at above be correct, one may picture a metal point on the verge of discharging as a smooth curved conducting surface studded all over with Grotthuss chains standing up on it like bristles. The density of charge upon it will thus be far from uniform. It will reach a maximum at the root of each chain, the quantity collected there being constant for a given gas, independent of the length of the chain, and equal perhaps to the ionic charge of the gas atoms. In between the chains the density will be much less.

Now the field, f, measured by the attraction of a plate on a needle-point is the average number of lines of force per square centimetre of the point-surface, and takes no account of the manner in which they are distributed over it. This is because the point is so small that the lines have room to become uniformly spread out before they reach the plate. Hence it follows that, for different dispositions of the chains, the measured values of f may be very different, and yet the number of lines of force running through each chain be the constant number corresponding to ionic charge on its atoms; f, in fact, for a given amount of induction per chain depends both on the length and on the closeness of the chains. Great length, or great closeness, or both, means that the greater part of the lines proceeding from the point have been absorbed by the chains, hardly any passing in between them. In this case f is practically proportional to the number of chains per square centimetre, and is independent of their lengths. On the other hand, very short chains, or very few to the square centimetre, or both, means that f is sensibly independent of their closeness, but is now dependent on their length, being inversely proportional thereto so long as it is not very great compared with the radius of curvature of the point. In between these two extremes f depends both on length and on closeness of the chains, varying in an inverse manner with the former, and in a direct manner with the latter.

Now, both length and closeness of the chains increase with increase of gas pressure; hence, there must be some pressure, A, above which f is sensibly proportional to the closeness of the chains only, and some lower pressure, B, below which it is inversely proportional to the chain-lengths only. In the neighbourhood of A increase of pressure will affect f chiefly by the resulting alteration of the closeness, and will therefore increase f. Near B it will have the opposite effect, as increase in the length of the chains means a decrease of f. Hence between A and B there must be some pressure for which f is a minimum. This point is, of course, well known to exist,* though I was unable to obtain a sufficiently good vacuum with my apparatus to reach it. If, however, f be expressed in terms of some power (n) of the pressure, n will be 0 at the minimum point, and positive and increasing as the pressure rises from there. This increase is shown well in Table III. (calculated from Table II. for positive discharge only—the negative is too uncertain). Here n_1 is calculated from the values of f, corresponding to 76 and 40 centimetres of mercury, and n_2 for 40 and 20 centimetres; n_2 is in every case less than n_1.

TABLE III.

L	10·9 „	0·52	0·46
M	31·8 „	0·61	0·58
N	45·7 „	0·69	0·61
O	58·0 „	0·69	0·56
X	400·0 „	[0·80]	0·72

The needle marked X was in reality a steel ball used for bicycle bearings. This was put opposite a tin disc of 6 centimetres diameter at a distance of 3·6 centimetres. n was calculated from measurements of the difference of potential between ball and plate, as f could not be measured. The values of n fit in well with the rest. (n_1 was calculated in this case from f at 40 and 60 centimetres mercury.)

Now pressure alters the length and closeness of the chains at the same time; but, for a given field strength at a point-surface, alteration in curvature gives rise to alteration of chain-length only, the length being less as the point gets sharper. Hence at a sharp point f is more dependent on the length of the chains than at a blunt one; it is, in fact, nearer its minimum value, and n is consequently less. This, too, is shown very clearly in Table III.

* Rontgen, Weidemann's Electricitat, vol. iv., § 582.

A pretty illustration of the influence of point curvature on n was accidentally met with in the case of needle C. In getting it into the apparatus for repetition of the curves obtained with it, its point came against the metal box, and was flattened slightly to a width of about $3 \cdot 6 \cdot 10^{-3}$ centimetres. The values of n_1 and n_2 obtained from it after this were respectively 0·42 and 0·30, instead of 0·31 and 0·2 for the finer point.

Grotthuss chains, coupled with constant atomic charge, are thus well able to explain most of the phenomena described in this paper. There still remains one which is perhaps the most important of all—the difference in the behaviour of positive and negative discharge. This I hope to discuss in connection with experiments now in progress, but it may perhaps be well to place on record the results so far obtained.

These are given in Table IV., where k is the ratio at a pressure of 20 centimetres of f for positive discharge to f for the negative. The ratio shows a distinct tendency to decrease as r increases. It is almost useless to give values at higher pressures on account of the uncertainty as to the condition of the point, and the great effect this may have on the negative discharge (Curves III.); but the ratio is distinctly less at higher pressures, for points which seemed quite clean; the decrease of k at 70 centimetres mercury varying from 3 to 8 per cent. as compared with k at 20 centimetres. For dirty points the decrease may reach 50 per cent.

Description of Apparatus.

§ 8. The electrometer used for potential measurements was constructed on the principle of the one designed some years ago for

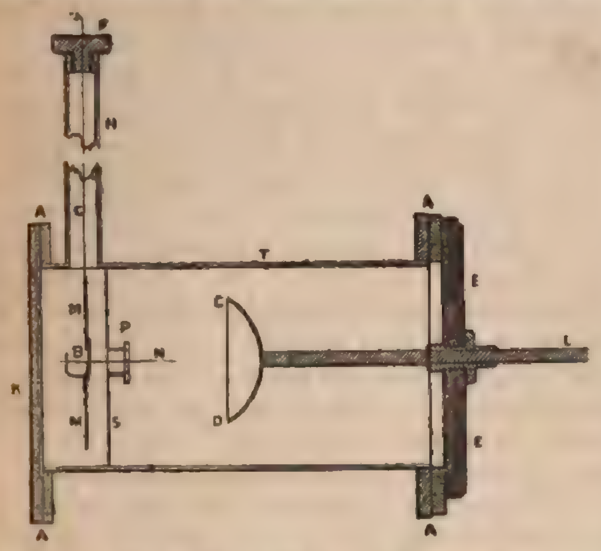

FIG. 1.—T, brass tube forming body of instrument; length 10 centimetres, diameter 6 centimetres.
H, tube for suspension wire, G. F, ebonite plug.
M, mica disc suspended from G, carrying light metal clip B, holding needle N.
S, tin screen soldered into T.
K, metal cover. E, ebonite cover.
A A, ground air-tight joints, greased.
C D, spherical metal cup to be electrified; C D = 3·35 centimetre, radius of curvature = 1·76 centimetre.
P, short brass tube on S; length = 0·5 centimetre, diameter = 1·2 centimetre.
Point of N at centre of curvature of C D. Length of needle projecting beyond P = 2 centimetres.

absolute measurement of much smaller quantities by Prof. Minchin. The attracted disc is suspended, and the force of attraction measured by tilting the whole instrument until the disc falls back by its weight to a fixed point. The disc is a sheet of mica, covered on one side with tinfoil and metallically connected with the case of the instrument, which is a tin cylindrical box 30 centimetres long by 30 centimetres diameter. The disc hangs just outside a 3in. hole in a tin screen at one end of the case, and opposite the hole inside the case is an adjustable disc of tin which forms the attracting plate. The sensitiveness of the instrument may be varied very greatly by altering the distance between this plate and the suspended disc. This arrangement does not of course permit of absolute measurement, but it was thought that calibration in terms of spark-lengths was sufficiently accurate for the work in hand.

The same principle of tilting was used in measuring the attractions on the needle-points; the needle in this case taking the place of the suspended disc. The zero position was determined by a hair in the eye-piece of a microscope through which the point of the needle was observed; the latter being at the centre of curvature of C D, Fig. 1, when it coincided with the hair. The needle was illuminated by small windows in T (not shown). L was connected to the Wimshurst; T to earth; and G—*i.e.*, N—through a high-resistance galvanometer to earth, the indications of the galvanometer being therefore due only to current discharged from N. A much larger instrument, constructed on the same lines, was used for needle A and other measurements. The body of this instrument is a tin cylinder, 43 centimetres long (horizontally) and 23 centimetres in diameter. The needle is suspended in a small metal box at the centre, and the electrified plate is supported like C D, Fig. 1, from one end.

The tilting is effected in each of the above instruments by fixing them to a brass base, provided with pivots at one end and a vertical micrometer-screw with large divided head at the other. The method works admirably.

In conclusion, I wish to express my thanks to my friend Mr. F. B. Fawcett, a former student of University College, Bristol, and to my assistant Mr. J Quick, for much careful help in carrying out the measurements described in this paper. To Prof. Lodge my thanks are so numerous that I cannot express them. His kindness, both by word and by deed, has been unceasing. Indeed but for him this paper would probably never have been written.

Results.

1. Point-discharge depends only on the strength of field close to the point between pressures of 76 and 10 centimetres.
2. Field here measured absolutely by its pull on the point.
3. Seat of resistance to discharge shown to be in gas only, for a clean point (Grotthuss chain).
4. Atomic charge, probably of same order of magnitude as ionic charge.
5. Effects of pressure and of point-surface curvature in accordance with Grotthuss chains.

PORTSMOUTH.

Mr. Shoolbred suggests in his report to the Portsmouth Town Council the low-tension system for private lighting with storage batteries, and the three-wire system for distribution, using armour-protected cables, laid underground, and embedded without any other covering whatever. The capacity of the electrical installation which he recommends to be laid down at first would be of a maximum output of 5,000 lights each of 16 c.p., burning at one time. This figure of 5,000 lights would mean a total of about 8,000 lights connected with the system of distribution. The buildings at the generating station should, however, be constructed large enough to contain without addition generating plant for about double the electrical output above mentioned, so as to allow for reasonable extension of the first supply. The boilers preferred are of the Lancashire type, steel and double-flued, working at 180lb. pressure per square inch. He recommends that steam engines of the inverted vertical type, running at moderate speeds, driving the dynamo direct, and placed in the same bed-plate therewith, be adopted. The sizes of steam engines which he recommends are those capable of developing 150 i.h.p. and 75 i.h.p. respectively. Should sea water for condensing purposes be not readily available (and it is not at present in central Portsmouth) the engines should be one of the compound non-condensing type.

The capital expenditure for this part of the scheme is put at £45,000, and the revenue at £10,390, with a profit calculated to reach £1,451. We do not agree with Mr. Shoolbred's estimates—£10,390, with a maximum even of 8,000 lights wired, is rather more than we should expect, but as a rule the maximum number of lights estimated for are not wired for some years. For the public lighting Mr. Shoolbred suggests arc lights, the figures for which are: Cost of 25 lights on the Clarence Esplanade, 25 on the South Parade, with engines, dynamos, boilers, cables, lamps, and posts, etc., £5,500; 40 arc lights at refuges and other prominent points in streets named in the electric lighting order, with engines, dynamos, etc., £5,000; contingencies, 10 per cent., £1,050; making a total of £11,550.

The committee, having considered the general question of the electric lighting of Portsmouth, and inspected the s[illegible] in vogue elsewhere, stated they were of opinion that [illegible] furnished by Mr. Shoolbred was the best t[illegible] adopted. They had come to the conclusion, a[illegible] enquiry, that the low-pressure system was the m[illegible] reason of its absolute safety and economy i[illegible] further advantage of this system was that it [illegible] for motive power. In Mr. Shoolbred's report [illegible] the installations for public and private lightin[illegible] £56,550; but to this should be added a sum f[illegible] and meeting other expenses. The comm[illegible] that Mr. Shoolbred's report be adopted, and [illegible] made to the Local Government Board for [illegible] £60,000 for the purposes of the electric ligh[illegible]

THE

ELECTRICAL ENGINEER.

Published every Friday.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

IMPORTANT NOTICE.

We may occasionally follow the lead of our American Contemporaries, especially when they point out a serviceable way. They are not backward in asking their friends to do all they can for the welfare of the paper. We ask our friends to remember us. No Paper that we know ever refuses Subscribers or Advertisers. Nor do we; in fact, we invite them, believing that they will get full value for their money.

Specimen copies of the paper will be sent on request.

IS THE ELECTRIC LIGHT A FAILURE?

Such is the title of an article, describing an interview with Mr. W. H. Massey, which appeared in the *Oracle* of September 5th. It is not often one looks to professed financial papers for well-considered opinions upon any subject. The lucubrations given therein are too often biassed and intended to influence market operations. The *Oracle*, however, can hardly be classed as a purely financial paper; in fact, it seems a kind of olla podrida, touching upon art and sport as fluently as it touches upon finance. Its "interviews" are generally well done, and record opinions of experts upon the question of the moment. Last week the *Times* article upon the progress of electric lighting in London, and Mr. Massey's comment thereon, evidently struck the note which led to the interview. Our opinion upon certain points put forward by the *Times*, and commented upon by Messrs. Massey and Crompton, as expressed in our last issue, seems to meet the general view. The past is historical. Nothing that can be said or done now will alter it. Let bygones be bygones, but take care for the present and the future. The *Oracle* interviewer does not bring out so clearly as he might the emphatic answer to his title question. The electric light is not a failure, but many of the professed advocates of the electric light are not only failures—they are fools. They imagine any tale, be it as far-fetched as that of Sinbad the Sailor, may advantageously be used to induce people to patronise electricity. One of the most foolish, one of the most stupid arguments ever introduced, was the comparison of the cost of gas and of electricity. Mr. Massey, during the interview referred to, is reported to have said: "It is suicidal in my view for people to say that they can supply electricity at anything like the price of gas. It was because people said that that the maximum charge settled by Parliament was fixed too low. . . It is such a good light, both from the point of view of illumination and sanitation, that there is no reason why it should be pitted against gas." Mr. Massey's views relating to companies' profits and to patents are well worthy of consideration, but we think he is rather hard upon the companies. It may be agreed that at present a sufficient time has not elapsed to prove the accuracy of their accounts, to determine exactly what should and what should not be charged to capital. Far too much is usually put to capital account by managers of most companies. However, there is more depending upon the policy of the supply companies for commercial success than upon the question of accounts. Mr. Massey says, and this appears the crux of the whole matter, "I myself think that these public supply stations would have a much better chance of success if they were to go in by day for the supply of power, and by night for the supply of light. But in the early years of their existence they should in any case charge a sufficiently high price to pay their way." The general public will accept Mr. Massey's criticisms as by far the most valuable that have appeared, in that he is totally unconnected with any firm or any

supply company. He is known also as a very blunt exponent of his carefully arrived at conclusions. In all new departures the public has to be educated by interested parties, which renders it necessary that as occasion requires the more sensational statements should be toned down somewhat by those who view the question more dispassionately. If those interested in supply companies will take as much trouble to educate possible customers to use power as well as light they will certainly make their paths, paths of greater pleasantness, and bring about that happy time when their machinery can be used to the greatest advantage—when they can obtain the greatest output at the least cost per unit, and hence when the commercial value of electrical apparatus can be fully exploited.

STILL THE B. A.

Mr. Walker's criticisms of the British Association are in some cases a little too severe. Surely it cannot be expected that the evening lectures, for example, should partake of the character of scientific "pap." It serves to show how very varied are the opinions regarding the association's work, for a goodly number of critics have looked upon these evening lectures as *the* redeeming feature at each successive meeting. As to Prof. Rücker's lecture this year, we think that the general consensus of opinion is altogether favourable. Commencing with simple optical knowledge, gradually, as it were, link by link extending the width of knowledge, experimentally showing step by step the similarity of optical and electrical phenomena, Prof. Rücker carried his audience through the whole lecture without verbal redundancy or aught but the simplest language, so clearly delivered that no one starting with the flimsiest fundamental notions could fail to follow all that was said and to comprehend the beauty of the analogies experimentally brought forward. We should never fear for the future of an association that depended for preservation upon such lectures. There would be no falling off in numbers nor in interest—rather the contrary. Prof. Rücker's lecture was worth going to Cardiff and becoming a member of the association in order to hear. Those who attend these lectures are expected to have obtained a sufficient groundwork of scientific knowledge upon which the lecturer can build. They should not be learners in the sense of starting with absolute ignorance of the subject, but should be learners in the sense of having the necessary fundamental knowledge to follow the lecturer into some special path in which few have previously trod, and which till then is more or less hidden from the multitude.

We have no objection to criticise freely the sectional arrangements, or the monetary arrangements, but we could not, if we would, find one word of fault or of disparagement to a lecture such as that of Prof. Rucker's. A condemnation may be too sweeping to be effective, and we imagine Mr. Walker will after further consideration agree that the British Association cannot be expected to ask its lecturers to confine themselves to elementary subjects solely to benefit those still in the wilderness, nor, again, must it be expected that the presidential address be such as to be understanded of the multitude. This address is either a record of general progress, of progress in some one science, or the epitomised work of a lifetime. Few have trod the whole path delineated, and the address marks at the moment the uttermost point which has been reached. History starts afresh from this point, and so the record grows. Who would have it otherwise?

HELMHOLTZ'S BIRTHDAY.

On August 31 Prof. Helmholtz celebrated his seventieth birthday at Madonna de Campiglio, where he is spending the holidays.

Campiglio is an old monastery converted into an hotel, and stands at a height of 6,000ft. in the mountains of the Austrian Tyrol. It is accessible by a 13 hours' drive from Trient on the one side, and by a mule track over the Mendola Pass on the other, and commands views of the Bocca di Brenta and other famous mountains. There is no village, and the hotel stands miles from any other habitation.

Prof. Helmholtz is accompanied by Madame Helmholtz, by his sister (Baroness Schmidt Zabirow) and her husband (his Excellency Baron Schmidt Zabirow), and by his daughter (Mrs. Werner Siemens) and her husband (Mr. Werner Siemens, jun.)

At an early hour an illuminated address of congratulation, prepared by Herr Josef Hofer, the well-known Munich artist, who is also staying at Campiglio, and signed by all the visitors, was presented, and subsequently the visitors called on Prof. and Madame Helmholtz to offer their congratulations. Prof. Helmholtz's rooms were profusely decorated with flowers. Among those who called were Prince and Princess Molfetta, Prof. Dr. von Bayer (the well-known chemist), La Duchesse di Melzi, and her daughter, the Comtesse di Melzi, Herr Josef Hofer (Munich), Herr von Dechy (Budapest), Herr von Gündel (Hamburg), Mr. and Mrs. J. E. H. Gordon (London), Canon and Mrs. Harvey (Lincoln), Mr. and Mrs. Jennett Brown (Meran).

Later in the day a dinner was given to Prof. Helmholtz, when his health was drunk with great enthusiasm, while the peasants' band played under the windows. Prof. Helmholtz is in the best of health and spirits, and looks nearer 60 than 70.

CORRESPONDENCE.

"One man's word is no man's word
Justice needs that both be heard."

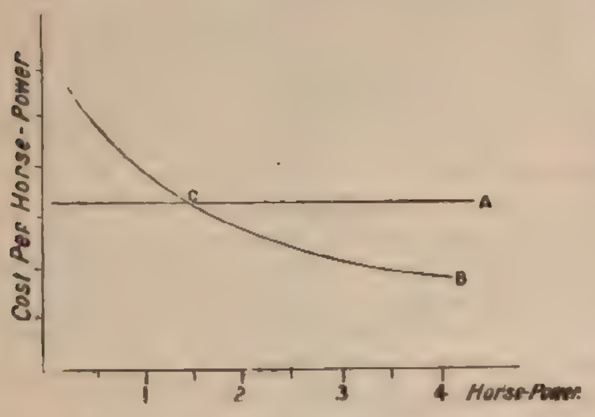
THE WEYMERSCH [illegible]

SIR,—While thanking you fo [illegible] ce of our
battery, may I point out one [illegible] h might
possibly be misleading. You [illegible] gives a
steady current of 20 amperes a [illegible] ours, the
cost being given by the syndic [illegible] ling per
unit." Now, the cost per unit [illegible] ate wit
the price of zinc, and of the [illegible] for pr
ducing the depolarising fluid [illegible] price
the above articles the cost p [illegible] 5d. a

1s. 6d. Should the price of zinc fall to what it was a few years ago, this, coupled with the fact that as the demand for depolarising solution becomes greater it is possible to make it more cheaply, would cause the cost per unit to fall to the figure named in your article.

I have troubled you with this perhaps unnecessary explanation because so many primary batteries, which promised marvellous things, and have enjoyed but an ephemeral existence, have come before the public, that it is wise to state that the Weymersch Syndicate do not claim to compare the burning of zinc as fuel with the burning of coal on the basis of cost only, and do not wish to claim extravagant advantages for the use of their primary battery in directions which are manifestly outside the legitimate scope of such an apparatus.

If I am not trespassing at too great a length on your valuable space, I might just call attention to the following diagram which may be taken to illustrate the field open to a good primary battery. Taking everything into account—viz., absence of all risks, of explosions, absence of moving



machinery, and simplicity in manipulation (no technical skill being necessary)—line A may be taken to represent the cost per horse-power of energy generated by the "chemical" engine, so to speak, while curve B may be taken to represent the cost when generated by a steam, gas, or petroleum motor. The cost per horse-power from the primary cannot vary very much for small or large powers, while the efficiency of a steam engine increases with the size and power of the engine. Assume that A and B intersect at about C, then it may be considered that for electric light installations of about 20 8-c.p. lamps it is less trouble to use the primary battery than a steam or gas engine and dynamo, but that beyond this the difference in cost becomes considerable. Speaking generally, it may be taken that where not more than 1 h.p. to $1\frac{1}{2}$ h.p. is required it is worth while to produce this by means of the primary battery, more especially if the installation is to be left in the hands of non-technical attendants.

It is, of course, needless to add that the battery can be used for a variety of purposes other than the production of electric light.—Yours, etc., ED. C. DE SEGUNDO,

Executive Engineer, The Weymersch Electric Battery Syndicate, Limited.

London, S.W., Sept. 5.

MISSIONARIES OF SCIENCE AND THEIR DUTY.

SIR,—It is perhaps somewhat bold for one of the rank and file in the great army of scientific workers to presume to criticise the action of his leaders. But when on all sides is heard the voice of widespread dissatisfaction with the proceedings of the British Association, perhaps the incipient mutiny may be pardoned.

The *Speaker* solemnly warns the association to put its house in order, or be prepared to go the way of the now defunct Social Science Association. Local papers in the town recently honoured by the presence of the association loudly complain that though a heavy tax is levied upon the town and district by the association, absolutely nothing is given by that body in return. Only one lecture of a popular character, that by Prof. Silvanus Thompson, was vouchsafed to the hungry souls that were thirsting for knowledge in the town, and that mainly owing to the determination of the professor himself. Perhaps it may be of advantage to enquire what the proper function of the British Association really is. If it were an exclusive body, such as the Royal Society, or the Institution of Civil Engineers, who paid a visit to certain localities at its own expense, aided possibly by subscriptions from its own local members and other sympathisers, no one would have any right to complain of the way in which it transacted its business. But it does not do this. It settles down upon the town it delights to honour for the year, like an octopus, embracing and practically stopping to a large extent the commercial life of the town. Numerous halls must be provided, and all the accessories of the headquarter staff of an army in the field, with its post and telegraph office, its executive, and, in addition, comfortable lounging-rooms. A large sum must be contributed by the people of the district, with the peculiar proviso that no matter how much an individual may subscribe to this local fund, he is not entitled to listen to any of the words of wisdom that are poured forth, unless he becomes for the time a member or associate. And all this is claimed on the ground that the presence of the association awakens the intellectual life of the town and district. Those who knew not what wonders science has wrought, and will do, are to know it now. The association is no exclusive body demanding guarantees of work done as a qualification for membership. Anyone may become a member or an associate, even a baby in its cradle, if only someone will pay the sum of one or two pounds into the coffers of the association.

And there is no doubt that large numbers of ladies and gentlemen join the association when it happens to be located in their midst, in the hope that they will learn something of the wonders of science they have heard about. But when the great parliament of science, as it has been inaptly termed, arrives, they find that in order to reap the harvest they had hoped for, they must belong to an inner trained circle. They may attend lectures upon supposed popular subjects—upon subjects they would be glad to hear about, but the lecturers might as well talk in Hindustani for the amount of information that is conveyed to the minds of at least 90 per cent. of their hearers. With every respect for the simple student who so ably filled the chair upon the present occasion, and for the splendour of his lifelong work, how many of his audience could possibly follow his opening address? How many, for instance, outside of the circle of scientific students know what a spectroscope is, and how many of those were able to grasp the method described by the president of measuring the approach or recess of certain fixed stars from our earth? How many, even among his audience, would understand what he meant by a measurement comprising so many seconds of arc?

So, too, with Prof. Rücker's lecture on "Electric Stress." To students of electrical phenomena it was a rare treat, and the writer of this article gratefully acknowledges many important truths learned from it. But to the mass of the audience, what interest could it have, beyond the appearance of light or its disappearance, and the appearance of certain colours or their non-appearance, just as the lecturer willed? And, except in rare cases, what lessons could they carry away.

It has been the same in other towns. At Bath, for instance, one of the lectures was given by an able professor of geology on "The Foundation Stones of the Earth's Crust"; but instead of the lecturer explaining to his audience how geologists make out that the earth has been built up in geological time, he proceeded to hold an intensely technical argument with some invisible opponent upon some theory of the formation of some particular rocks, and the argument, which was plentifully interspersed with such terms as gneisses and schists, was perfectly unintelligible and absolutely without interest to any but the geologists present. Is this fulfilling the duty which the British Association owes to those who support it, and to those for whom presumably it works? Does the advancement of science mean throwing the ball of argument round a particular circle of players, and never allowing outsiders a chance to

in the game? Does it mean keeping the achievements ience also within this charmed circle? Would it not oing more real good, advancing the interests of science substantially if outsiders—those who pay the bill— allowed to listen to the tune. Surely it must be rent that the object of discovery is not to be boxed o that only a few can know of its existence, but to be ad broadcast, to bear fruit. Every scientific fact that n or woman learns, and can apply intelligently, adds e wealth of the world in some form or other; and the missionary of science is he who proclaims his message nguage that can be understood by everyone.

ut there is also another and a very serious complaint d against the association, and with good reason. Practical say that its discussions and its papers are merely playing ience. They rarely advance science at all, because the rs are usually only half read, and *never* properly ssed. From seven to twenty papers are down to be and discussed in the time required for one, conse- tly the first is *sometimes* read, never properly discussed, second half read, and the rest lost. Why cannot these ers be arranged in a proper manner? Why should ors be asked to go to the trouble of preparing papers diagrams, bringing up elaborate apparatus, and then to et by the insulting request to read their papers to an ence of, say, three, or, if they do read them before a y large audience, to be constantly interrupted by nders from the chairman that time is short?

ow, also, is it possible to intelligently discuss a paper h you hear for the first time, and then perhaps in a led form, owing to the constant interruptions? Why ot the example of the leading engineering institutes be wed—only as many papers be accepted as can be read properly discussed, these papers carefully examined re being accepted and printed in advance, so that all are interested in the subject can have an opportunity tudying the paper? Surely one paper given under conditions would be worth a hundred given under present arrangements.

lso, is it not possible to avoid the tactics of the election form in discussions which take place on papers presented e British Association? A smart personal sally may cause gh, but it is hardly conducive to the advancement of ce, and is very undignified. Surely it should be in the power of the presidents of the sections to see their discussions do not degenerate into personal bbles, as unfortunately is too often the case at present. A differs from something stated in Mr. B's paper, with Mr. C states that Mr. A knows nothing of the ect. Surely it would not only be more dignified, but effective, for Mr. C to point out where Mr. A is wrong. lso, would it not be best that there should be no uritism shown in the selection and order of taking of papers? Certainly give eminence the first place, but riendship.

rther, are not three hours daily as much as human head human eyes can endure, at any rate in one subject? not let some sections meet from ten till one, and others two till five? The mornings or afternoons that were ngaged could well be devoted to the inspection of local s, etc. It often happens that a member is interested o or more sections. The different branches of science verlap each other, and one can never tell when one is to receive a hint that will be useful in one's own ch, from something which appears before another ch. Geology, for instance, bears an important relation to th." It would be very convenient to attend, say, ion G in the morning and some other section in the noon; or, if there happened to be nothing on of est in the afternoon, to go over some works or other t of interest in the neighbourhood. Possibly other bers may offer other suggestions. At any rate, the r hopes that there may be less cause for dissatisfaction e Edinburgh meeting on the points he has named than has been hitherto, and that the British Association, rming to the altered conditions in which it finds , may become once more a body of true missionaries, ging home the teachings of science, not only to the red few, but to everybody within its reach.—Yours,

SYDNEY F. WALKER.

THE GLASGOW ELECTRICAL ENGINEER.

As in the days to come local authorities will not only have their ordinary engineers, but also a specialist as electrical engineer answering somewhat in position to that of gas engineer, or water engineer, it may be as well to watch the gentlemen who secure these positions. One of the first appointments is that at Glasgow.

At the last meeting of the Town Council of Glasgow a recommendation from the Gas and Electric Lighting Committee to appoint Mr. William Arnot, of London, as the electrical engineer to the Corporation was approved of. There were about 50 applications for the appointment, the candidates hailing from all parts of the kingdom. After the first examination of the applications a list of 18 of the most likely men was made out, then a short list of six was selected, and each of these candidates had a personal interview with the sub-committee on electric lighting, after which it was unanimously agreed to recommend the appointment of the gentleman named above. Mr. Arnot, who is an associated member of the Institution of Civil Engineers, and a full member of the Institution of Electrical Engineers, is 36 years of age, and has an excellent "record," his practical experience in connection with the electric lighting industry being alike varied and extensive, and his training in theory and practice in the university and workshop having been very thorough. He had sole charge of the erection and maintenance of the Brixton central lighting station, in which both arc and incandescent plants were put down, and in which both overhead and underground circuits were run. He ran the mains for Plymouth Pier—arc and incandescent lamps, and laid several large underground mains, including those for Buckingham Palace. For over four years Mr. Arnot was employed in the electrical department of the Silvertown Works, and during that time, in addition to the usual electrical installation work, he superintended the laying down of all the plant for the Cannon-street central lighting station. In this case the plant embraced Babcock and Wilcox boilers and direct-driven engines, and dynamos for 1,000 lights, together with switchboards and fuse-boards, which were of his own design. While in that employment he was also engaged in the estimating for electrical plants; indeed, he has had a large amount of experience in estimating for all classes of work, and has put down a number of installations with gas engines and secondary batteries. His experience also includes the fitting up electrically of a number of her Majesty's warships. For some time Mr. Arnot had the management of the engineering department of Messrs. Latimer Clark, Muirhead, and Co.'s works at Millwall, where he constructed a large number of dynamos, arc lamps, and other machinery. Then, again, it may be mentioned that he had for a length of time charge of the high-tension electric lighting station at the Grosvenor Gallery, when the directors decided to adopt Mr. Ferranti's system and engaged his services. Several years ago Mr. Arnot did some excellent work in connection with the laying of electric lighting mains in the country for Callender's Bitumen, Telegraph, and Waterproof Company, Limited, from whose manager he holds a high-class testimonial. During the past 18 months he has been employed as the electrical inspector for the London County Council, and his work in that capacity at the meter-testing station is spoken of in a very generous manner by Prof. Silvanus Thompson, who is the consulting electrical engineer to the Highways Committee of the County Council. After an acquaintanceship extending over six years, Mr. Ferranti likewise bears most excellent testimony in favour of Mr. Arnot, whom we must, in closing this notice, heartily congratulate on receiving the first appointment of the kind in Scotland, and in a city where he may expect to have Sir William Thomson as "guide, philosopher, and friend."

THE BRITISH ASSOCIATION AT CARDIFF.

light, but
in opposite

two stars revolve round their common centre of gravity in a plane not perpendicular to the line of sight, all the lines in a spectrum common to the two stars will appear alternately single or double.

In the case of Mizar and the other stars to be mentioned, the spectroscopic observations are not as yet extended enough to furnish more than an approximate determination of the elements of their orbits.

Mizar especially, on account of its relatively long period—about 105 days—needs further observations. The two stars are moving each with a velocity of about 50 miles a second, probably in elliptical orbits, and are about 143 millions of miles apart. The stars of about equal brightness have together a mass of about 40 times as great as that of our sun.

A similar doubling of the lines showed itself in the Harvard photographs of β Aurigæ at the remarkably close interval of almost exactly two days, indicating a period of revolution of about four days. According to Vogel's later observations, each star has a velocity of nearly 70 miles a second, the distance between the stars being little more than $7\frac{1}{2}$ millions of miles, and the mass of the system 4·7 times that of the sun. The system is approaching us at the speed of about 16 miles a second.

The telescope could never have revealed to us double stars of this order. In the case of β Aurigæ, combining Vogel's distance with Pritchard's recent determination of the star's parallax, the greatest angular separation of the stars as seen from the earth would be 1-200th part of a second of arc, and therefore very far too small for the highest powers of the largest telescopes. If we take the relation of aperture to separating power usually accepted, an object glass of about 80ft. in diameter would be needed to resolve this binary star. The spectroscope, which takes no note of distance, magnifies, so to speak, this minute angular separation 4,000 times; in other words, the doubling of the lines, which is the phenomenon that we have to observe, amounts to the easily measurable quantity of 20 seconds of arc.

There were known, indeed, variable stars of short period, which it had been suggested might be explained on the hypothesis of a dark body revolving about a bright sun in a few days, but this theory was met by the objection that no such systems of closely revolving suns were known to exist.

The Harvard photographs, of which we have been speaking, were taken with a slitless form of spectroscope, the prisms being placed, as originally by Fraunhofer, before the object-glass of the telescope. This method, though it possesses some advantages, has the serious drawback of not permitting a direct comparison of the star's spectrum with terrestrial spectra. It is obviously unsuited to a variable star like Algol, where one star only is bright, for in such a case there would be no doubling of the lines, but only a small shift to and fro of the lines of the bright star as it moved in its orbit alternately towards and from our system, which would need for its detection the fiducial positions of terrestrial lines compared directly with them.

For such observations the Potsdam spectrograph was well adapted. Prof. Vogel found that the bright star of Algol did pulsate backwards and forwards in the visual direction in a period corresponding to the known variation of its light. The explanation which had been suggested for the star's variability—that it was partially eclipsed at regular intervals of 68·8 hours by a dark companion large enough to cut off nearly five-sixths of its light—was therefore the true one. The dark companion, no longer able to hide itself by its obscureness, was brought out into the light of direct observation by means of its gravitational effects.

Seventeen hours before minimum Algol is receding at the rate of about $24\frac{1}{2}$ miles a second, while 17 hours after minimum it is found to be approaching with a speed of about $28\frac{1}{2}$ miles. From these data, together with those of the variation of its light, Vogel found, on the assumption that both stars have the same density, that the companion, nearly as large as the sun, but with about one-fourth his mass, revolves with a velocity of about 55 miles a second. The bright star of about twice the size and mass moves about the common centre of gravity with the speed of about 26 miles a second. The system of the two stars, which are about $3\frac{1}{4}$ millions of miles apart, considered as a whole, is approaching us with a velocity of 2·4 miles a second. The great difference in luminosity of the stars—not less than 50 times—suggests rather that they are in different stages of condensation, and dissimilar in density.

It is obvious that if the orbit of a star with an obscure companion is inclined to the line of sight, the companion will pass above or below the bright star and produce no variation of its light. Such systems may be numerous in the heavens. In Vogel's photographs, Spica, which is not variable, by a small shifting of its lines reveals a backward and forward periodical pulsation due to orbital motion. As the pair whirl round their common centre of gravity, the bright star is sometimes advancing, at others receding. They revolve in about four days, each star moving with a velocity of about 56 miles a second in an orbit probably nearly circular, and possess a combined mass of rather more than $2\frac{1}{2}$ times that of the sun. Taking the most probable value for the star's parallax, the greatest angular separation of the stars would be far too small to be detected with the most powerful telescopes.

If in a close double star the fainter companion is of the white-star type, while the bright star is solar in character, the composite spectrum would be solar with the hydrogen lines unusually strong. Such a spectrum would in itself afford some probability of a double origin, and suggest the existence of a companion star.

In the case of a true binary star the orbital motions of the pair would reveal themselves in a small periodical swaying of the hydrogen lines relatively to the solar ones.

Prof. Pickering considers that his photographs show 10 stars with composite spectra; of these, five are known to be double. The others are: τ Persei, ζ Aurigæ, δ Sagittarii, 31 Ceti, and [illegible] Capricorni. Perhaps β Lyræ should be added to this list.

In his recent classical work on the rotation of the sun, Dunér not only determined the solar rotation for the equator, but at different parallels of latitude up to 75deg. The close accordance of his results shows that these observations are sufficiently accurate to be discussed with the variation of the solar rotation for different latitudes, which had been determined by the older astronomical methods from the observations of the solar spots.

Though I have already spoken incidentally of the invaluable aid which is furnished by photography in some of the applications of the spectroscope to the heavenly bodies, the new power which modern photography has put into the hands of the astronomer is so great, and has led already, within the last few years, to new acquisitions of knowledge of such vast importance, that it is fitting that a few sentences should be specially devoted to this subject.

Photography is no new discovery, being about half a century old. It may excite surprise, and, indeed, possibly suggest some apathy on the part of astronomers, that though the suggestion of the application of photography to the heavenly bodies dates from the memorable occasion when, in 1839, Arago, announcing to the Académie des Sciences the great discovery of Niepce and Daguerre, spoke of the possibility of taking pictures of the sun and moon by the new process, yet that it is only within a few years that notable advances in astronomical methods and discovery have been made by its aid.

The explanation is to be found in the comparative unsuitability of the earlier photographic methods for use in the observatory. In justice to the early workers in astronomical photography, among whom Bond, De la Rue, J. W. Draper, Rutherfurd, Gould, hold a foremost place, it is needful to state clearly that the recent great successes in astronomical photography are not due to greater skill nor, to any great extent, to superior instruments, but to the very great advantages which the modern gelatine dry plate possesses for use in the observatory over the methods of Daguerre, and even over the wet collodion film on glass which, though a great advance on the silver plate, went but a little way towards putting into the hands of the astronomer a photographic surface adapted fully to his wants.

The modern silver-bromide gelatine plate, except for its grained texture, meets the needs of the astronomer at all points. It possesses extreme sensitiveness; it is always ready for use; it can be placed in any position; it can be exposed for hours; lastly, it does not need immediate development, and for this reason can be exposed again to the same object on succeeding nights, so as to make up by several instalments, as the weather may permit, the total time of exposure which is deemed necessary.

Without the assistance of photography, however greatly the resources of genius might overcome the optical and mechanical difficulties of constructing large telescopes, the astronomer would have to depend in the last resource upon his eye. Now, we cannot by the force of continued looking bring into view an object too feebly luminous to be seen at the first and keenest moment of vision. But the feeblest light which falls upon the plate is not lost, but is taken in and stored up continuously. Each hour the plate gathers up 3,600 times the light energy which it receives during the first second. It is by this power of accumulation that the photographic plate may be said to increase, almost without limit, though not in separating power, the optical means at the disposal of the astronomer for the discovery or the observation of faint objects.

Two principal directions may be pointed out in which photography is of great service to the astronomer. It enables him within the comparatively short time of a single exposure to secure permanently with great exactness the relative positions of hundreds or even of thousands, of stars, or the minute features of nebulæ or other objects, or the phenomena of a passing eclipse, a task which by means of the eye and hand could only be accomplished, if done at all, after a very great expenditure of time and labour. Photography puts it in the power of the astronomer to accomplish in the short span of his own life, and so enter into their fruition, great works which otherwise must have been passed on by him as an heritage of labour to succeeding generations.

The second great service which photography renders is not simply an aid to the powers the astronomer already possesses. On the contrary, the plate, by recording light-waves which are both too small and too large to excite vision in the eye, brings him into a new region of knowledge, such as the infra-red and the ultra-violet parts of the spectrum, which must have remained for ever unknown but for artificial help.

The present year will be memorable in astronomical history for the practical beginning of the Photographic Chart and Catalogue of the Heavens, which took their origin in an international conference which met in Paris in 1887, by the invitation of M. l'Amiral Mouchez, director of the Paris Observatory.

The richness in stars down to the ninth magnitude of the photographs of the comet of 1882 taken at the Cape Observatory under the superintendence of Dr. Gill, and the remarkable star charts of the brothers Henry, which followed two years later, astonished the astronomical world. The great excellence of these photographs, which was due mainly to the superiority of the gelatine plate, suggested to these astronomers a complete map of the sky, and a little later gave birth in the minds of the Paris astronomers to the grand enterprise of an International Chart of the Heavens. The actual beginning of the work this year is in no small degree due to the great energy and tact with which the director of the Paris Observatory has conducted the initial steps through the many delicate and difficult questions which have unavoidably presented themselves in an undertaking which depends upon the harmonious working in common of many nationalities, and of no fewer than 18 observatories in all parts of the world. The three

years since 1887 have not been too long for the detailed organisation of this work, which has called for several elaborate preliminary investigations on special points in which our knowledge was insufficient, and which have been ably carried out by Profs. Vogel and Bakhuyzen, Dr. Trépied, Dr. Scheiner, Dr. Gill, the Astronomer Royal, and others. Time also was required for the construction of the new and special instruments.

The decision of the conference in their final form provide for the construction of a great photographic chart of the heavens with exposures corresponding to 40 minutes' exposure at Paris, which it is expected will reach down to stars of about the fourteenth magnitude. As each plate is to be limited to four square degrees, and as each star, to avoid possible errors, is to appear on two plates, over 22,000 photographs will be required. For the more accurate determination of the positions of the stars, a *réseau* with lines at distances of 5 mm. apart is to be previously impressed by a faint light upon the plate, so that the image of the *réseau* will appear together with the images of the stars when the plate is developed. This great work will be divided, according to their latitudes, among 18 observatories provided with similar instruments, though not necessarily constructed by the same maker. Those in the British dominions and at Tacubaya have been constructed by Sir Howard Grubb.

Besides the plates to form the great chart, a second set of plates for a catalogue is to be taken, with a shorter exposure, which will give stars to the eleventh magnitude only. These plates, by a recent decision of the permanent committee, are to be pushed on as actively as possible, though as far as may be practicable plates for the chart are to be taken concurrently. Photographing the plates for the catalogue is but the first step in this work, and only supplies the data for the elaborate measurements which have to be made, which are, however, less laborious than would be required for a similar catalogue without the aid of photography.

Already Dr. Gill has nearly brought to conclusion, with the assistance of Prof. Kapteyn, a preliminary photographic survey of the southern heavens.

With an exposure sufficiently long for the faintest stars to impress themselves upon the plate, the accumulating action still goes on for the brighter stars, producing a great enlargement of their images from optical and photographic causes. The question has occupied the attention of many astronomers whether it is possible to find a law connecting the diameters of these more or less over-exposed images with the relative brightness of the stars themselves. The answer will come out undoubtedly in the affirmative, though at present the empirical formulæ which have been suggested for this purpose differ from each other. Captain Abney proposes to measure the total photographic action, including density as well as size, by the obstruction which the stellar image offers to light.

A further question follows as to the relation which the photographic magnitudes of stars bear to those determined by eye. Visual magnitudes are the physiological expression of the eye's integration of that part of the star's light which extends from the red to the blue. Photographic magnitudes represent the plate's integration of another part of the star's light, namely, from a little below where the power of the eye leaves off in the blue, to where the light is cut off by the glass, or is greatly reduced by want of proper corrections when a refracting telescope is used. It is obvious that the two records are taken by different methods in dissimilar units of different parts of the star's light. In the case of certain coloured stars the photographic brightness is very different from the visual brightness; but in all stars changes, especially of a temporary character, may occur in the photographic or the visual region, unaccompanied by a similar change in the other part of the spectrum. For these reasons it would seem desirable that the two sets of magnitudes should be tabulated independently, and be regarded as supplementary of each other.

The determination of the distances of the fixed stars from the small apparent shift of their positions when viewed from widely-separated positions of the earth in its orbit is one of the most refined operations of the observatory. The great precision with which this minute angular quantity, a fraction of a second only, has to be measured, is so delicate an operation with the ordinary micrometer—though, indeed, it was with this instrument that the classical observations of Sir Robert Ball were made—that a special instrument, in which the measures are made by moving the two halves of a divided object-glass, known as a heliometer, has been pressed into this service, and quite recently, in the skilful hands of Dr. Gill and Dr. Elkin, has largely increased our knowledge in this direction.

It is obvious that photography might be here of great service, if we could rely upon measurements of photographs of the same stars taken at suitable intervals of time. Prof. Pritchard, to whom is due the honour of having opened this path, aided by his assistants, has proved by elaborate investigations that measures for parallax may be safely made upon photographic plates, with, of course, the advantages of leisure and repetition; and he has already by this method determined the parallax for 21 stars with an accuracy not inferior to that of values previously obtained by purely astronomical methods.

The remarkable success of astronomical photography, which depend upon the plate's power of accumulation of a very feeble light acting continuously through an exposure of several hours, are worthy to be regarded as a new revelation. The first chapter opened when, in 1880, Dr. Henry Draper obtained a picture of the nebula of Orion; but a more important advance was made in 1883, when Dr. Common, by his photographs, brought to our knowledge details and extensions of this nebula hitherto unknown. A further disclosure took place in 1885, when the brothers Henry showed for the first time in great detail the spiral nebulosity issuing from the bright star Maia of the Pleiades, and shortly afterwards nebulous streams about the other stars of this group. In 1886 Mr. Roberts, by means of a photograph, to which three hours' exposure had been given, showed the whole background of this group to be nebulous. In the following year Mr. Roberts more than doubled for us the great extension of the nebula region which surrounds the trapezium in the constellation of Orion. By his photographs of the great nebula in Andromeda, he has shown the true significance of the dark canals which have been seen by the eye. They are in reality spaces between successive rings of bright matter, which appeared nearly straight owing to the inclination in which they lie relatively to us. These bright rings surround an undefined central luminous mass. I have already spoken of this photograph.

Some recent photographs by Mr. Russell show that the great rift in the Milky Way in Argus, which to the eye is void of stars, is in reality uniformly covered with them. Also quite recently Mr. George Hale has photographed the prominences by means of a grating, making use of the lines H and K.

The heavens are richly but very irregularly inwrought with stars. The brighter stars cluster into well-known groups upon a background formed of an enlacement of streams and convoluted windings and intertwined spirals of fainter stars, which becomes richer and more intricate in the irregularly rifted zone of the Milky Way.

We, who form part of the emblazonry, can only see the design distorted and confused; here crowded, there scattered, at another place superposed. The groupings due to our position are mixed up with those which are real.

Can we suppose that each luminous point has no relation to the others near it than the accidental neighbourship of grains of sand upon the shore, or of particles of the wind-blown dust of the desert? Surely every star from Sirius and Vega down to each grain of the light dust of the Milky Way has its present place in the heavenly pattern from the slow evolving of its past. We see a system of systems, for the broad features of clusters and streams and spiral windings which mark the general design are reproduced in every part. The whole is in motion, each point shifting its position by miles every second, though from the august magnitude of their distances from us and from each other, it is only by the accumulated movements of years or of generations that some small changes of relative position reveal themselves.

The deciphering of this wonderfully intricate constitution of the heavens will be undoubtedly one of the chief astronomical works of the coming century. The primary task of the sun's motion in space, together with the motions of the brighter stars, has been already put well within our reach by the spectroscopic method of the measurement of star-motions in the line of sight.

From other directions information is accumulating: from photographs of clusters and parts of the Milky Way, by Roberts, in this country; Barnard, at the Lick Observatory, and Russell, at Sydney, from the counting of stars, and the detection of their configurations, by Holden and by Backhouse; from the mapping of the Milky Way by eye, at Parsonstown; from photographs of the spectra of stars, by Pickering, at Harvard, and in Peru; and from the exact portraiture of the heavens in the great international star chart which begins this year.

I have but touched some only of the problems of the newer side of astronomy. There are many others which would claim our attention if time permitted. The researches of the Earl of Rosse on lunar radiation, and the work on the same subject and on the sun, by Langley. Observations of lunar heat with an instrument of his own invention, by Mr. Boys; and observations of the variation of the moon's heat with its phase, by Mr. Frank Very. The discovery of the ultra-violet part of the hydrogen spectrum, not in the laboratory, but from the stars. The confirmation of this spectrum by terrestrial hydrogen in part, by H. W. Vogel, and in its all but complete form by Cornu, who found similar series in the ultra-violet spectra of aluminium and thallium. The discovery of a simple formula for the hydrogen series by Balmer. The important question as to the numerical spectral relationship of different substances, especially in connection with their chemical properties; and the further question as to the origin of the harmonic and other relations between the lines and the groupings of lines of spectra; on these points contributions during the past year have been made by Rudolf v. Kovesligethy, Ames, Hartley, Deslandres, Rydberg, Grunwald, Kayser and Runge, Johnstone Stoney, and others. The remarkable employment of interference phenomena by Prof. Michelson for the determination of the size, and distribution of light within them, of the images of objects which when viewed in a telescope subtend an angle less than that subtended by the light-wave at a distance equal to the diameter of the objective. A method applicable not alone to celestial objects, but also to spectral lines, and other questions of molecular physics.

Along the older lines there has not been less activity; by newer methods, by the aid of larger or more accurately constructed instruments, by greater refinement [illegible], knowledge has been increased, especially in precision [illegible] exactness.

Astronomy, the oldest of the [illegible] than renewed her youth. At no time in the past [illegible] so bright with unbounded aspirations and hope[illegible] her temple [illegible] numerous, nor the crowd of her [illegible] The [illegible] Astronomical Association formed [illegible] about 600 members. Happy is t[illegible] eastern side of life's meridian!

Already, alas! the original [illegible] are falling out—Kirchhoff, A[illegible] Becquerel: but their places a[illegible] race is gaining, but the goal is [illegible]

Since the time of Newton [illegible] nature has wonderfully incr[illegible]

earnestly now than in his days, what is the ultimate reality behind the reality of the perceptions? Are they only the pebbles of the beach with which we have been playing? Does not the ocean of ultimate reality and truth lie beyond?

RECENT PROGRESS IN THE USE OF ELECTRIC MOTORS.*

BY PROF. G. FORBES, F.R.S.

In any comparatively new industry, as electrical engineering, a great deal of mental "striction" must be got over to get people to adopt new methods even when known to be an improvement.

Lord Rayleigh in his presidential address in 1884 expressed his astonishment that while no addition to our electrical knowledge of 50 years previously was required to develop the dynamo, it was so slow in being introduced. The same is true in England now, even of electrical inventions which have been proved by long and extensive experience in other countries to be economically desirable.

It is the duty of engineers who see and inspect such work abroad, to urge upon people at home the importance of their inventions, and point out the troubles which have been met and overcome elsewhere so as to avoid failure, and to point out the directions in which different inventions are being adopted, modified, or rejected, as the result of extensive practical experience. Even in electric lighting, I am sure more than one company will admit that in following this rule some of us have saved them from buying costly experience in the past. In saying this I recognise the fact that all countries look upon England as having improved the dynamo more than any other country. In the application of electric motors I have noticed three directions in which this country needs the testimony of independent and impartial people to assist the value of applications which in some other countries are generally adopted. These are (1) electric railways, (2) replacing shafting in shops, especially for cranes, by electric conductors and motors, (3) transmitting power to a distance from waterfalls by means of electricity.

My remarks on these heads are largely founded on experience gained in visits to the United States, and also from a very thorough investigation of the utilisation of water power in all parts of Switzerland, undertaken this summer in conjunction with Prof. Unwin.

1. *Electric Railways.* — These are thoroughly established in America on the cheapest system—*i.e.*, electricity supplied from a central station by overhead wires. The extensive adoption of electric tram lines in America, and the small number in England, is entirely due to the fact that they allow these overhead conductors and we do not generally do so. The electric lines in America are one-half of the horse car lines in number, and are rapidly ousting horse lines as well as steam and cable lines; and yet it is extremely difficult to get correct figures of the cost. The most trustworthy estimates seem to vary between 4.18 and 6.00 cents per car mile, including coal, attendance, land, buildings, machinery, line, oil, water, and waste. The question of repairs is serious and must be reduced. Most of the lines adopt spur gearing to reduce the speed from the electric motor to the car axles. They generally use two pinions and two spur wheels. This introduces great friction. It is very generally accepted that 8 h.p. is lost in gear friction, though this seems somewhat incredible, being about 30 per cent. These cars are large, and the motors are 30 h.p. This enormous power is absolutely demanded to enable them to start on a gradient with facility, and they do this. There is no crawling about these cars. You feel that there is plenty of power for the work. The noise on these cars used to be very considerable, and the injury to watches through magnetisation was at one time an objection. The noise from the gearing, especially when worn, has been deadened by enclosing the motor and gearing in cast-iron boxes. The magnetisation of watches is prevented by adopting a suitable type of motor. The type first advocated, I believe, by Eickmeyer in America, and myself in England, in which the magnetising coils are wound round the armature when we want the magnetism instead of round the field magnets, is now being adopted by the Thomson-Houston Company, which has done such splendid work in street railways.

Another source of trouble in motors used to be the brushes, for sparking is liable to be very violent with the variable load of a tram motor, and the commutators wear away rapidly. Since my carbon brushes have been introduced this difficulty has entirely disappeared, and the motors can be used with any variation of load, and can be reversed without wearing of the commutator and with very little sparking. Even in stationary motors they are now generally adopting these brushes, and also in dynamos.

The loss in double reducing gear and the wear and tear led to all the important companies turning to single reducing gear with rather heavier motors. It would at first appear impossible to go further, and adopt armatures on the wheel axles without sacrificing the great advantage of gearing which allows the motors to be independently supported without being subjected to the same shocks as the wheel axles. In spite of this, the Westinghouse Company has introduced a gearless motor, which has strength enough to stand the shocks. But other inventors had the idea of fixing the armature alone on the axle and supporting the field magnet wholly on springs—to support it partially on springs is of little value. Now, with ordinary motors the armature cannot have up and down motion relatively to the pole-pieces. But Mr. Short, of the Brush Company, introduced a motor with pole-pieces, the sides of which allows an up and down motion without fear of the armature windings striking the pole-pieces. If the difficulty of end thrust is overcome, this ought to be an important step. But in this direction the most important and promising plan seems to be that adopted by Eickmeyer and Field. They support the whole motor in guides on springs, and connect the motor axle and the wheel axle by cranks and a coupling bar, the cranks on the right and left sides being at right angles to each other. This serves to reduce gearing friction to a minimum, while completely obviating shocks.

It may be well to give the result of American experience as to the injuries from shocks to the motor. In the first place, every manufacturer there has had to buy his own experience on one head—viz., that all loose wires such as those which join the magnet coils, or those passing from armature to commutator, are fractured by vibration. This experience has been universal, and the South London Electric Railway has also bought the same experience. The remedy lies in making such loose connections of flexible stranded wire. The other serious result of vibration is that the insulation, especially of the armature, is broken off, and short circuits occur. In America spur gearing is almost universal, but in Switzerland the Oerlikon Company are introducing worm gearing, which has been so much approved by M. Reckenzaun. Storage batteries have not generally been successful in America, but some trials have worked very well. In the last few years I have seen several of them in the States which seemed to promise well, but nothing has come of them.

The Thomson-Houston Company are now experimenting with heavy locomotives to drag trailer cars. They have not yet decided to adopt them, and in the plans proposed for rapid transit in New York I see a tendency to go in for separate motors on all the axles of a train, which is the only plan that utilises all the characteristic advantages of electric motor propulsion for long and rapid trains. We thus abolish the excessive weight of a locomotive, we are able to use lighter and less expensive rail, wear and tear of permanent way is diminished, and grinding action in going round curves. If trains are supplied by sufficient power they are not limited by rail friction to going up slight inclines, nor to getting up speed slowly. On a line with many stops the time occupied in a complete journey is thus largely reduced.

2. *Replacing Shafting by Electricity.*—The benefit of replacing shafting by electric conductors and motors has been thoroughly appreciated in America. Everyone knows of the hundreds of motors for small work which are supplied with electricity by central stations in Boston and New York besides other places, and of the large number of electric lifts supplied by the Otis Company, with the electric motors designed by Eickmeyer. I will only place before English manufacturers two of the establishments where a statement of what has been done is enough to bring conviction to the mind of every shrewd and sensible employer of power. In the great works of William Sellars and Co., shafting has been abolished as far as possible. I saw seven motors at work, chiefly on cranes. I saw a 15-h.p. Sprague motor working a 30-ton travelling crane, which has been in continuous use for the last two years. They, of course, use carbon brushes, and the motor has never given any trouble. Ordinarily working at 200 volts and 60 amperes, the latter have been increased to 110 for a short time without injury. There are also electric connections all over the shop, by means of which motors can be used at any time. The second establishment is Baldwin's locomotive factory, where 16 to 20 locomotives are sent off every week, and where space is so valuable that there is no room for shunt lines, and where a 100 ton travelling crane picks up one out of these 20 and puts it down where wanted. This fine travelling crane and every other crane in this huge part of the works are driven by electric motors.

3. *Transmitting Power to a Distance.*—With regard to transmission of power to a distance from waterfalls, I have seen little to chronicle in America, and what there is seems rather antiquated, but in Switzerland important work has been done by continuous and alternating currents. The high-tension electrical work in connection with continuous currents that most impressed me was what has been done by Cuenod, Sautter, and Co., Geneva. Their six-pole machines, with Gramme commutators, up to 2,000 volts, designed by M. Thury, seem to work admirably and sparklessly, and I must here state my conviction, which I did not previously have, that the insulation of such a machine can be made perfect, as there done, by supporting the dynamo or motor on a number of alternate slabs of vulcanised rubber and porcelain, and by connecting the shafts by Raffard couplings. This consists of a disc in the end of each of the two shafts to be coupled, which are as nearly in line as possible. Each disc has half-a-dozen steel pins on a circle near its periphery. In one of the discs the circle of pins is, say, 1ft. diameter, and in the other 1ft. 6in., and the two circles of pins are in the same place and are connected in pairs by india-rubber rings. This avoids the necessity of perfect alignment and ensures perfect insulation. At Oyonnax, a small village with artisans who make combs and wooden pipes and other articles, the lathes are driven by electric motors from a low-pressure supply. To get this power, a waterfall six miles distant is used. Each turbine, of 120 h.p., drives a dynamo of 1,800 volts, which is sent by overhead conductors to Oyonnax, where it drives a 1,800-volt motor, which drives a low-tension dynamo which supplies three three-wire circuits—one for power, one for public light, and one for private light. They have supplied similar plant in many other places.

I will not take up time with describing different works of this kind, but I will now say something about the use of multiphase or rotary currents, about the prospective use of which so much has been published. I have seen the machines and transformers in course of construction at Oerlikon, and the insulators which

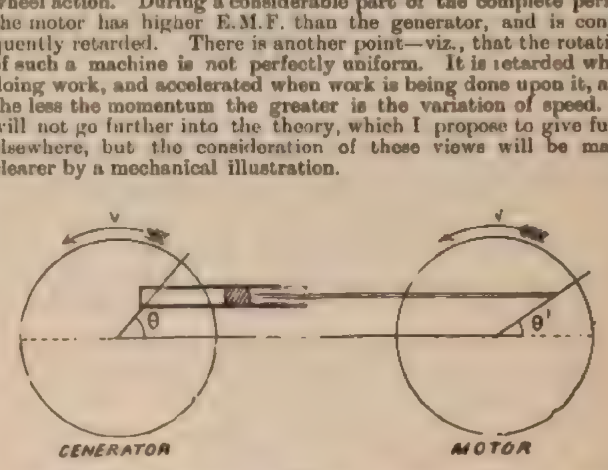
* Paper read before the British Association.

have been used, and the mechanical design is excellent. This plant is now about to be tried at Frankfort over a distance of 112 miles. Tests will be made, and we shall soon know something definite about their working. I have not seen the Dobrowolski machines, but both these and the others have been described in the technical journals. The principle employed by Mr. Brown, of Oerlikon, is the fact, discovered by Wilde, that an alternating dynamo used as a generator will drive a second similar machine as a motor; but three separate circuits are put on the armatures, so that three separate currents travel along the line and reach the electric motor in succession, so that there is alway one circuit at least on the armature of the motor, tending to drive it round. Now these three currents in the line will interfere seriously with each other—just as it was found at New Orleans, that two circuits in unusual proximity for 1½ miles, and fed by two separate alternators, interfered with each other so much that the lamps on both circuits flickered badly. I find that, in order to prevent this, it is necessary that along the whole line the three conductors shall be at the corners of an equilateral triangle. I can quite understand the difficulties of regulation of three currents referred to by Dobrowolski, but I think there are further points upon which information is much wanted. I want to know—for hitherto I have entirely failed to see—the advantages of this three-phase synchronising alternator over the simple alternators which do such excellent work. I have been told that Mr. Brown's machine has 96 per cent. of efficiency as a dynamo. Well, I reply that an ordinary alternator without iron, not having the hysteresis of Mr. Brown's machine, ought to have a higher efficiency. In the next place, I am told by Mr. Brown that while you cannot switch one of these three-phase synchronising motors with its load on to an electric circuit and expect it to get up to the synchronising speed, yet it will do so along with the electric generator of electricity if the latter be also started from rest. In this it certainly has the advantage over the synchronising alternator with iron, but none whatever over those without iron, which will act in precisely the same way unless the motor happens to be stopped on dead centres—*i.e.*, with the centres of coils (in a Mordey alternator, for example) halfway between poles of the field magnets.

If this is the only gain over single-phase alternators with self-induction, and if there be no advantage gained over alternators without large self-induction, I fail to see the merit of the complication of three phases. I would not have drawn attention to the absence of advantage, but would have preferred to await the experiments before expressing an opinion, were it not for the great attention directed to the scheme by the Press, altogether out of proportion to the results which Mr. Brown and the Oerlikon managers hope to obtain. The great experiment about to be tried at Frankfort, which interests electricians all over the world, is not to prove that transformation is efficient, but to prove that 30,000 volts can be carred along 112 miles of overhead conductor. The Dobrowolski motor does not resemble the synchronising motor, but is a modification of the Tesla motor, except that the number of currents of differing phase is increased. Here also I fail to see any cause of better work, but I await any trials that may be made with interest, and I speak as one who has worked with and made tests with the developed type of Tesla motor at Pittsburg. Mr. Dobrolwolski, however, says that whatever load may be put on this motor there is no serious difference in phase between the potential difference applied to the motor (and there is no appreciable lag) and the current. If this be so, it would be a decided improvement, but I shall require strong proof before I accept the multiphase motor as a great advance over the Tesla machine. The only advantage which it possesses over synchronising alternators without iron in the armature, and with large momentum, lies in its power to start with load on. But I do not see that in large applications this advantage is to be compared with what it loses by its want of synchronism. All shops ought to be driven at a steady speed, but in some trades, such as weaving with sensitive looms, it is essential, and even the best turbines driven at nearly constant fall, if not governed, cause the breaking of threads in a loom to be a serious drawback. On the whole I would prefer the synchronising type. But Mr. Dobrowolski claims that these machines have the further advantage over the synchronisers that they will not stop when overloaded. Now this prevalent prejudice requires examination. For my own part, after having tested Mr. Mordey's synchronising alternators on many occasions, and after having very much overloaded them, I have a strong conviction, almost amounting to a feeling of certainty, that it is impossible to put them out of step in ordinary conditions by merely increasing the load. The more you increase the load, the more current goes through them to keep them in step. They would rather get red hot than get out of step. They behave just as a continuous-current motor, or a Tesla motor, or a Dobrowolski motor behave under the same conditions. It gets hots, but it does not stop. At this stage I must say that it is much to be deplored that no conclusive experiments by any independent authority have as yet been made on the Mordey alternator as to its efficiency when used as a motor.

In concluding my remarks about the Frankfort experiment, I wish to express the admiration that electricians feel for the men who have undertaken to prove that 30,000 volts can be practically transmitted overhead for 112 miles; and for the engineers who have so ably designed such excellent mechanical machines to do the work.

I now have a word to say on the alternating synchronising motor, which it seems so difficult to get people to believe in. I have for some time past been working at its theory. I will not go into the mathematics of it now. I will content myself with stating the conclusions, and replacing analytical or geometrical proofs by a mechanical analogy. People seem to be strangely at a loss to explain why it is that some alternators work well as motors while others do not. It has been shown that self-induction will assist this action. So many people have rushed to the conclusion that self-induction is the cause, and many a machine has been thrown away that was built on these lines. Mordey overthrew these views by showing that his machine, having less self-induction than most alternators, synchronised the best. Then, when we compare the Siemens or Ferranti alternator with the Mordey one, we see that they are electrically identical, especially as to self-induction. Why, then, does the Mordey work so well as a motor and not the Ferranti? The explanation is simply that the former has a large momentum and the other has not. I announced this explanation of the difficulty at a meeting of electricians in Paris last February, and found that M. Hospitalier had arrived at exactly the same conclusion and quite independently. I feel confident in predicting that the Ferranti dynamo, if supplied with a heavy enough flywheel, will be found to work as well as the Mordey machine as a motor. The reason of this is that the motor has dead centres to get over, just like a steam engine. During the alternations the current is reduced to zero twice during each complete period, so also is the back E.M.F. of the motor, and at each of these points we have dead centres beyond which the motor cannot move except by flywheel action. During a considerable part of the complete period the motor has higher E.M.F. than the generator, and is consequently retarded. There is another point—viz., that the rotation of such a machine is not perfectly uniform. It is retarded when doing work, and accelerated when work is being done upon it, and the less the momentum the greater is the variation of speed. I will not go further into the theory, which I propose to give fully elsewhere, but the consideration of these views will be made clearer by a mechanical illustration.



Imagine two wheels on independent axles connected by a coupler which is not rigid, but consists of a piston attached to one of the wheels and a cylinder attached to the other; the piston working in the cylinder. If one of these is driven and slowly increased in speed, the other will rotate with it, but if it be loaded with a brake it cannot get over the dead centres unless it has momentum. Here the air friction, varying as the relative velocity of piston and cylinder, is the force which moves the motor wheel, and this corresponds to the electric current conveyed in the electric motor analogy. It is supposed that the wheels are so distant that the coupler is always parallel to the line of centre. The E.M.F. of either machine is represented by the inclination of the line of the coupler to tangent of the wheel at its point of attachment.

In the electrical problem, if θ and θ^1 are the phases of generator and motor, and if v and v^1 are their velocities at the moment, and if M and M^1 are the strengths of field, then, omitting self-induction altogether, their E.M.F.'s are proportional to

$$M\,v \sin \theta \text{ and } M^1 v^1 \sin \theta^1;$$

the current to

$$(M\,v \sin \theta - M^1 v^1 \sin \theta^1,$$

and the work on the motor to

$$M^1 v^1 \sin \theta^1 (M\,v \sin \theta - M^1 v^1 \sin \theta^1) \quad . \quad . \quad . \quad . \quad (A)$$

In the mechanical model the force transmitted is proportional to the relative motion of cylinder and piston—*i.e.*, to

$$v \sin \theta - v^1 \sin \theta^1,$$

and the pressure in the tangential direction moving the motor is

$$(v \sin \theta - v^1 \sin \theta^1) \sin \theta,$$

and the work on the motor is

$$v^1 \sin \theta^1 (v \sin \theta - v^1 \sin \theta^1),$$

which is an expression of exactly the [illegible]), the electrical expression. Hence, the mechanic[illegible] ical problem is exactly represented by the [illegible] model, and the influence of momentum [illegible] d by the mechanical engineer, and h[illegible] entum is essential for synchronous acti[illegible]

ELECTROLY[illegible]

BY ROBERT [illegible]

The study of Clerk M[illegible] electric energy through [illegible] through the magnificen[illegible] from the purely mathe[illegible] it to the elucidation of [illegible]

* Paper read before [illegible]

tion of electric energy through that class of conductors known as electrolytes.

The propagation of electric energy along metallic conductors is invariably found to produce the following four phenomena:

I The electric energy is propagated with the velocity of light.

II. An electromagnet field is produced.

III. Induced currents are produced in neighbouring conductors.

IV. Heat is produced in the conductor uniformly along its length proportional to the strength of the current and the resistance of the conductor.

These four phenomena are also produced during electrolysis. They are, however, accompanied by a fifth phenomenon—namely, chemical decomposition at the electrodes, and this chemical decomposition is strictly proportional to the strength of the current, but not to its intensity.

Hence, by infinitely increasing the potential and diminishing the strength of the current, we can make the absorption of electrical energy due to chemical action as small as we please; and thus we can establish so complete an analogy between the propagation of electric energy along metallic conductors and along electrolytes that any views brought forward to explain the phenomena in the one case must perforce apply to the other.

The theory of the propagation of electric energy along metals has been thus concisely defined by Prof. J. J. Thomson:

"The velocity of transmission of an electric impulse along a wire is, according to Maxwell's theory, equal to the velocity with which light passes through the dielectric in which the energy resides, and the function of the wire seems merely to be that of guiding the discharge which travels at a rate fixed by the dielectric."

Prof. H. Hertz has recently shown that when an electric oscillation travels along a wire the electric force produces a mechanical effect at right angles to the wire, whilst the magnetic force which accompanies it tends to repel a ring brought into its vicinity; thus there are two vibrations perpendicular to each other, the nodes of the one coinciding with the antinodes of the other, passing along the wires, whence he concludes that "from the above experiments with conductors of very simple form it is evident that a conductor of any form, when placed in the path of electromagnetic wires, is subject to forces of a very complex character."

Since a guiding conductor surrounded by dielectric is required (according to the above theory) for the propagation of electric energy in definite directions, the question arises, "How can an electrolyte act as such a guiding conductor?"

For this there are two possible explanations. Either (I.) the bulk of the electrolyte might be considered the conductor, and the surrounding medium the dielectric, such as glass or air, or (II.) in the electrolyte itself a rearrangement of molecules is produced, some (*i.e.*, the best conducting) forming the guiding conductors along the lines of force between the electrodes, other dielectric tubes surrounding the same.

The first proposition is untenable, for although it explains how an electromagnetic field may be produced outside the electrolyte, it utterly fails to explain how a fairly uniform field is produced inside it.

Molecular chains have formed the basis of every theory of electrolysis since they were first proposed by Grotthus, although the mode of action of the molecules has been explained in a great number of different ways.

The molecular arrangement required for the second proposition—*i.e.*, molecular chains surrounded by dielectric tubes—was first proposed by Prof. G. Wiedemann, who brings weighty proofs in its favour, but who also, like his predecessors, assumes that the current passes through the molecular chain. He has, however, provided the requisite mechanism for the application of Clerk Maxwell's theory to electrolysis.

The electric energy in being propagated through these dielectric tubes along the chain of conducting molecules produces these magnetic and electric effects, which act chemically on the dielectric, decomposing the molecules into atoms or weakening their affinity along the zones of intense electric action surrounding each molecular chain. A similar view was already suggested by Faraday, when he considers the electric current to be "an axis of power having contrary forces exactly equal in amount in opposite directions," modifying the chemical affinity of the electrolyte in directions parallel to the axis, and providing the conditions for the transfer of electro-positive and negative ions in their respective directions.

That there is a tendency for a strong electric field to produce molecular decomposition is evident from the action of the silent discharge and the elect[illegible], and also from such observations as those made by Bouty of electrolytic action on the surface of condenser plates.

The view proposed, which considers metallic and electrolytic conduction as identical, finds strong support in the following investigations.

Prof. J. J. Thomson finds, as the result of experiments, "that the velocity of propagation of a rapidly alternating current along an electrolyte surrounded by air cannot differ much from the rate along a wire"; and in examining the resistance of electrolytic alternating currents, "The results obtained agree sufficiently well to enable us to say that the relative resistance of electrolytes is the same when a current is alternating a hundred million times a second as for a steady current."

Prof. Mengarini, of Rome, in a very exhaustive paper on electrolysis by alternating currents, formulates the following law: "4. A limiting value to the rapidity of alternations exists, beyond which decomposition does not take place," which he proves both theoretically and experimentally; and he finds that at the limit "the voltameter only becomes heated by the passage of the current like an ordinary metallic conductor. He also states in his conclusions "6. A voltameter traversed by an alternating current behaves like a metallic conductor possessing self-induction."

A committee appointed by the British Association has also investigated a series of solid compounds—such as sulphides and selenides—some of which conduct purely metallicly, others purely electrolytically, and others in both ways at the same time, and declared themselves unable to draw any marked line of distinction between these bodies.

To resume. The number of the molecular chains formed will depend on the strength of the electric field and on the concentration of the electrolyte, whilst the cross-sectional area of each zone of decomposition will depend on the strength of the current and number of chains, and the current density will be measured by the number of such chains in the cross-section of the electrolyte.

The existence of these zones explains—

I. How the atoms can travel along molecular chains towards their respective electrodes without recombination.

II. Why the atoms are given off as molecules at the electrodes only, because there the electric field, being weakest, and atoms of one kind preponderating, they combine and are given off.

By artificially weakening the electric field by introducing a metallic plate into the path of the molecular chains, such plate acts similar to an electrode. Mr. A. Tribe, by interposing silver plates in a copper sulphate cell, obtained one end coated with copper, the other with protoxide of silver, and found the boundary line of the zone of deposition to be at right angles to the line of flow of the current. This enabled him to observe the refraction of this line of flow by interposing a porous vessel with water, whose parallel sides were inclined at an angle of 45deg. to the sides of the rectangular electrolytic trough, a most important verification of the directive tendency of the current in an electrolyte.

Prof. J. J. Thomson has also shown that an electric field is weakened in the presence of a solid dielectric, because the surface tension is increased. Hence, if a solid dielectric is intruded into a zone of intense electric action, by sending the current through a porous diaphragm or a cracked glass plate, the fields will be weakened and atoms liberated, as abundantly proved by the experiments of Grotthus, F. Braun, Ostwald, Tamman, Overbeck, and others.

III. Why the atoms cannot escape through out of the liquid is explained by the directive force preventing the atoms escaping laterally out of the decomposing zones.

It is obvious that only an exceedingly small E.M.F. would be required to produce the minimum zone of decomposition necessary for electrolysis along a single or few molecular chains, and, since a weak electric field could only have a few lines of force, there would only be a few such rows, and this gives us an explanation for the electrolysis produced by the infinitesimal currents observed by Helmholtz, M. Deprez, and others.

Also, if two bad conductors of slightly varying conductivity be mixed—such as alcohol and water—the conditions are provided for electrolytic action, the better conducting forming the guiding conductors, the other dielectric tubes, whence a greatly increased conducting power is produced and observed; as witness the experiments of Gladstone and Tribe, Overbeck, Pouillet, Ayrton and Perry, and others.

This also explains the action of exceedingly minute quantities of impurities on influencing the conductivity of electrolytes.

The assumption that the solvent is primarily decomposed suffices to explain all the chemical phenomena observed in electrolytic cells, and was fully accepted by the older electricians, being specially worked out by Berzelius and his school.

The electrolysis of solutions by strong currents gives strong support to this view, for when constituents of the solvents are more rapidly generated than they can be absorbed by secondary chemical action they are given off in the free state. I have shown this to be the case for copper sulphate solutions, from which I have obtained oxygen and hydrogen by sufficiently increasing the strength of the current. Kohlrausch also states that in very dilute solutions water is decomposed.

The complicated phenomena classed under polarisation are mainly due to voltaic currents arising from chemical changes taking place at the electrodes and their physical effects.

The phenomenon known as wandering of the ions has been shown by Profs. Wiedemann and Quincke to be due to three causes.

I. The free charges on the surface of the molecular chains, producing motion in opposite directions of the salt and the solvent molecules.

II. The same effect being also produced by the free charges on the electrodes; and

III. By the electrification of the vessel containing the electrolyte, which latter they also consider to explain the phenomena known as electrical endosmose.

It is obvious that these explanations may also be adopted in connection with the above expressed views.

In order to corroborate the theory of molecular chains, I have carried out a series of experiments with different apparatus to study whether the displacement of the molecular conductors would influence the conductivity. I found that the resistance of a jet of electrolyte, which was caused to flow at varying speeds between the electrodes, rose proportional to the velocity of the electrolyte up to a maximum of about 10 per cent. of the total deflection. In order to ensure the result being solely due to the velocity of the jet and not to diminution of the area of the conductor, the electrodes, carefully insulated except at the places where the jets, one to each electrode, impinged, were kept immersed in separate cells

connected with a tube and provided with overflow tubes, the jet playing beneath the surface of the electrolyte. The result was in complete accordance with those previously obtained.

Faraday has shown that an interrupted current flowing through an electromagnet is able to induce a current in a secondary coil made of an indiarubber tube filled with an electrolyte wound round the keeper.

Considering it to be of interest to have both a primary and secondary coil of electrolytic conductor, I constructed two flat spirals of indiarubber tubing filled with acidulated copper sulphate, and provided with copper electrodes; for the primary a continuous current of 90 volts was employed, which was simply interrupted by means of an electric bell worked from an independent battery.

The secondary coil was connected with a Sir Wm. Thomson 60-ohm reflecting galvanometer; a thermo current giving 10 divisions was observed, but the effect of the induced alternating current was to produce intermittently deflections of over 50 divisions on each side of the zero, thus removing all doubt of the success of the experiment.

The complete analogy between an electrolyte and a high-resistance wire led me to suspect that if such a wire were inserted between the electrodes, electrolysis would be observed at the ends. On referring to the literature I found that Jacobi had obtained the desired result with a German silver wire in a copper sulphate solution, but did not obtain the result with platinum. Having some thin platinoid wire at hand I determined to repeat the experiment, coiling the wire to increase its resistance. Copper was deposited along about one half of it, beginning slowly at the negative electrode whilst the other half turned black by oxidation, and was gradually destroyed at the end nearest the positive electrode.

I know that the view I have ventured to bring before you leaves many facts connected with electrolysis as yet unexplained, but the same must be admitted for all other theories on the subject hitherto propounded, over which it has, I believe, the advantage that it brings the propagation of electric energy along electrolytes into harmony with the now generally accepted theory of Clerk Maxwell of its propagation along metallic conductors, and that it offers an explanation of the electrical as well of the chemical phenomena observed.

ON THE ELECTROMAGNETIC THEORY OF THE ROTATION OF THE PLANE OF POLARISED LIGHT IN A MAGNETIC FIELD.*

BY PROF. A. GRAY, M.A.

Sir William Thomson has explained the turning of the plane of polarised light in a magnetic field by supposing the ether to have embedded in it a large number of small gyrostats, having the undisturbed positions of their axes in the common direction of the magnetic force, and the propagation of the beam, and all rotating in the same sense. When, in consequence of the vibratory motion, each gyrostat has its axis of rotation displaced from this direction it reacts on the surrounding medium with transverse force at right angles to the plane through the axis of rotation and the direction of motion.

By compounding this stress with the elastic forces of displacement of the ether, differential equations of motion are obtained which are of precisely the form necessary to account for the difference in rate of propagation of the two circularly polarised rays constituting the plane polarised ray.

The equations thus found are of the form:

$$\rho\frac{\delta^2 \xi}{\delta t^2} = n\frac{\delta^2 \xi}{\delta z^2} + c\rho\frac{\delta^3 \eta}{\delta t\,\delta z^2}$$

$$\rho\frac{\delta^2 \eta}{\delta t^2} = n\frac{\delta^2 \eta}{\delta z^2}c - \rho\frac{\delta^3 \xi}{\delta t\,\delta z^2}$$

where ξ η denote component displacements of a portion of ether in two rectangular directions, perpendicular to that of z, taken as the direction of propagation.

It is suggested by the gyrostatic investigation that it ought to be possible to explain the magneto-optic rotation on the electromagnetic theory of light, as a consequence of the existence of the similarly oriented small magnets which are supposed embedded in the medium with their axes in the direction of propagation of the ray, and therefore producing the magnetisation of the medium in that direction. Such a theory, while analogous to the gyrostatic theory, would be quite independent of the latter.

In consequence of the motions of the ether, the directions of the chains of magnetised molecules, which are supposed to exist along the direction of magnetisation (here taken as axis of z), in the undisturbed state of the medium, are continually undergoing change at every point, and thus the direction of the axial magnetic force along each chain also undergoes alteration. It is obvious that if the displacements be everywhere small the actual magnitude of this force will sustain only a very small percentage of alteration, but that each such small change of direction will produce a component magnetic force in each of the two directions at right angles to the axis. The calling into existence of these components will produce corresponding E.M.F.'s tending to increase or diminish the electric displacement.

* Abstract of a paper read before the British Association.

The E.M.F. in the direction of y is given in Maxwell's notation by

$$Q = \frac{dG}{dt} - \frac{\delta\psi}{\delta y},$$

where dG/dt stands for the total time-rate of change of G, the component of vector potential in the direction of y, and δ denotes partial differentiation. Also since H, the component along z, does not perceptibly vary along x, if the direction of propagation be as taken here along z $-\delta G/\delta z$, denotes magnetic induction through unit of area in the plane of yz. Hence any part of the total time-rate of variation of $-\delta G/\delta z$ will denote the space-rate of variation, in the direction of z, of an E.M.F. parallel to y, provided the time and space differentiations of the part are commutative. This is to be borne in mind in what follows.

Now, if the displacement of the ether particles from the undisturbed positions be taken as parallel and proportional to the electric displacement, and C be the component of magnetisation of the substance in the direction of z due to the existence of the molecular magnets, then, considering the electric displacement f in the direction of x, the component magnetic force in the direction of x will be, approximately, $e\,C\,\delta f/\delta z$, and thus the magnetic induction through unit of area in the plane of yz is $\mu\,e\,C\,\delta f/\delta z$, where e is a coefficient of proportionality. The time-rate of variation of this is

$$\mu\,e\,C\frac{\delta}{\delta t} \times \frac{\delta f}{\delta z}.$$

But we have by the equations of electric currents

$$\frac{\delta f}{\delta t} = \frac{1}{4\pi}\left(\frac{\delta\gamma}{\delta y} - \frac{\delta\beta}{\delta z}\right) = -\frac{1}{4\pi}\frac{\delta\beta}{\delta z}$$

since there is no conduction current.

Further, by the relation of magnetic force to vector potential, $\beta = (\delta F/\delta z)/\mu$, and therefore the last equation becomes

$$\frac{\delta f}{\delta t} = -\frac{1}{4\pi\mu}\frac{\delta^2 F}{\delta z^2}.$$

Now, since the differentiation of f with respect t is partial only, we may use the substitution

$$\frac{\delta}{\delta z}\frac{\delta f}{\delta t} = \frac{\delta}{\delta t}\frac{\delta f}{\delta z}.$$

Hence, differentiating $\delta f/\delta t$ with respect to z, we find

$$\mu\,e\,C\frac{\delta}{\delta t}\frac{\delta f}{\delta z} = \frac{e\,C}{4\pi}\frac{\delta^3 F}{\delta z^3},$$

which gives an E.M.F. in the direction of y of amount

$$\frac{-e\,C}{4\pi}\frac{\delta^2 F}{\delta z^2},$$

since there can be no constant or arbitrary time function concerned. Hence we have, finally,

$$Q = -\frac{\delta G}{\delta t} - \frac{e\,C}{4\pi}\frac{\delta^2 F}{\delta z^2} - \frac{\delta\psi}{\delta y},$$

and therefore
$$\frac{\delta Q}{\delta t} = -\frac{\delta^2 G}{\delta t^2} - \frac{e\,C}{4\pi}\frac{\delta^3 F}{\delta t\,\delta z^2}.$$

But the displacement current in the direction of y is dg/dt, and this is $K/4\pi \cdot \delta Q/\delta t$. Also by the equations of currents $\delta g/\delta t = -1/4\pi\mu\,\delta^2 G/\delta z^2$. Therefore we have the equation

$$\frac{K}{4\pi}\frac{\delta Q}{\delta t} = \frac{\delta g}{\delta t} = -\frac{1}{4\pi\mu}\frac{\delta^2 G}{\delta z^2},$$

which, used in the equation already found for $\delta Q/t$, yields

$$\frac{\delta^2 G}{\delta t^2} = \frac{1}{K\mu}\frac{\delta^2 G}{\delta z^2} - \frac{e\,C}{4\pi}\frac{\delta^3 F}{\delta t\,\delta z^2}.$$

Similarly for the other component in the case of circularly polarised light we find the equation,

$$\frac{\delta^2 F}{\delta t^2} = \frac{1}{K\mu}\frac{\delta^2 F}{\delta z^2} + \frac{e\,C}{4\pi}\frac{\delta^3 G}{\delta t\,\delta z^2}.$$

These two equations are identical in form with those quoted above, as given by the gyrostatic theory, and, of course, lead to the same results; that is to say, the plane of polarisation of an electromagnetic beam would show a turning effect in a magnetised medium.

The theoretical view given above has been suggested by a reference in M. Poincaré's "Théories de Maxwell," to a note by M. Potier, in his French transla[illegible] "Maxwell's Electricity," which appears to contain a si[illegible]ing to equations of the same form. REPORT OF THE COMMITTEE ON ELECTRICAL STANDARDS.*

Report of the committee consisting of Prof. G. Carey-Foster, Sir William Thomson, Prof. Ayrton, Prof. J. Perry, Prof. W. G. Adams, Lord Rayleigh, Dr. O. J. Lodge, Dr. John Hopkinson, Dr. A. Muirhead, Mr. W. H. Preece, Mr. Herbert Taylor, Prof. Everett, Prof. Schuster, Dr. J. A. Fleming, Prof. G. F. FitzGerald, Mr. R. T. Glazebrook (secretary), Prof. Chrystal, Mr. H. Tomlinson, Prof. W. Garnett, Prof. J. J. Thomson, Mr. W. N. Shaw, Mr. J. T. Bottomley, and Mr. T. Gray, appointed for the purpose of constructing and issuing practical standards for use in electrical measurements.

The work of testing resistance coils at the Cavendish Laboratory has been continued. A table of values found for the coils is appended.

B.A. UNITS.

No. of unit.	Resistance in B.A.U.	Temperature.
Elliott 245 —74	·99954	11·9
Elliott 246 —75	·99949	12·15
Elliott 248 —76	·99988	13·9
B.A. No. 38—77	1 00023	15·7
Elliott 257 —78	1·00046	15·6

LEGAL OHMS.

No. of coil.		Resistance in legal ohms.	Temperature.
McWhirter	L O —200	·99836	13·9
Elliott	244 —202	·99871	11·75
Elliott	250—203	·99924	13·9
Nalder	3,081—204	·99868	15·2
Elliott	258—205	·99985	15·4

Elliott	267—325	1·00040	16·
Nalder	3,059—326	1·00005	16·8

Among these the coil B.A. No. 38—77 has a special interest. It is an original platinum-silver coil which formerly belonged to Prof. Balfour Stewart, and is now in the possession of Prof. Schuster, at the Owens College. According to the label on it, it was right at 16deg. 5. According to my observations, its value is one mean B.A. unit at 14·9. This coil, therefore, would appear to have risen in value since about 1867 by ·0006 B.A.U., and this result is not in accordance with the conclusions deduced in 1878 from the observations on the other platinum-silver coils then examined.

Some further experiments have been made with satisfactory results on the air condensers of the association. A megohm resistance-box has been purchased for use in comparisons of capacity. With a view to testing the permanence of the resistance standards, it was thought desirable to compare them again with the mercury standards. This was done in December and January by the secretary. The coil that was compared with two mercury tubes constructed in 1884 by M. J. R. Benoit, which had been filled at Cambridge early in the year 1885 and had remained full since. An account of the comparison was read before the Physical Society, May 9, 1891, and appears in the *Phil. Mag.* for July, 1891. The coils were compared with the B.A. standards, if we take, as was done in 1885, for the resistance in B.A. units of a column of mercury 100 cm. long, 1deg. in section, the value ·95412 B A.U. We have the following results for the resistance of the tubes in legal ohms :

No.	Value in 1885 found by R T *b*.	Value in 1891 found by R T *b*.
37	99990	99986
39	99917	99913
